Lumleian Lectures

ON

SOME POINTS IN THE NATURAL HISTORY OF PRIMITIVE DRY PLEURISIES.

Delivered before the Royal College of Physicians,

BY SIR ANDREW CLARK, Bart., M.D.,

FELLOW OF THE COLLEGE.

LECTURE II.

Mr. President and Gentlemen,—A careful study of the cases related with more or less completeness in my first lecture leads naturally and necessarily to the second stage of this inquiry. A full understanding of the clinical demands a solution of the pathological problem; they are *inseparably connected, and find their common origin in* dynamic disturbances, which, although sometimes intangible, invisible, and incalculable, constitute the ultimate nature or essence of disease. What, then, is the nature of the visible pathological changes originating, underlying, maintaining, and continuing the symptoms and signs characteristic of *the course and issues of the cases* set forth as the grounds of this inquiry?

But before describing those changes as I have *observed* them in the course of my *examinations*, I must clear the way to the better understanding of them by some remarks on the minute anatomy of the lung, and *on the structural characters of a blood-clot* formed in freshly drawn blood.

Setting aside the earlier and in sundry ways admirable accounts of the minute anatomy of the lung given by Addison, Rainey, Rindfleisch, Schultze, Charcot, Luppey *Lefort*, and *Waters*, and confining our examination to the accounts *more recently* published *by such observers* as Schäfer and Klein, we shall learn from them the views received and adopted at the present time. Here is what Schäfer *says*:[1] "*After a certain stage* of subdivision, each bronchial tube reduced to a small *size is termed a lobular* or respiratory bronchial tube, and its walls become beset with *small hemispherical saccules* termed air-cells or alveoli. They occur at first only *here and there*, and confined to one side of the tube only, but at length almost cover it, *so that* the tube in a great measure loses its cylindrical character. At length *it ends in an enlarged* completely sacculated passage, termed the alveolar passage, *from which* are given off blind ramifications, somewhat enlarged towards their extremities, and everywhere closely beset with the air cells. These enlarged *terminations* are named *infundibula*." In order to give as exact an expression as *possible of* these views, he illustrates them by a diagram given at page 516 of the work already cited. From Klein's Atlas and from his more recent masterly little Handbook of Histology I extract the following account, which *on the whole is* the simplest, clearest, and most accurate of any hitherto published concerning the *minute anatomy* of the *pulmonary* parenchyma: "The small or intra-lobular bronchi are cylindrical tubes; they divide *dichotomously* into smaller tubes, and ultimately pass into the alveolar ducts, which *take* up on all sides of their circumference the lateral alveoli; the ultimate parts of the alveolar ducts are the *infundibula*, which take up the terminal alveoli. The alveoli are spherical or polyhedral *in* shape; and those belonging to the same alveolar duct or *infundibulum* are *separated* by much less tissue than the alveoli of adjacent *lobules*." *In the Handbook* (p. 220), it is further said that "all ducts or infundibula are closely *beset in their* whole extent with spherical, or being pressed against one *another* with polygonal, vesicles—the air cells or alveoli—opening by a wide aperture into the *alveolar* duct or infundibulum, but not communicating with each other. *The infundibula* are much wider than the terminal bronchiole, and also wider *than* the alveoli."

To Rainey and to both these distinguished observers is due the merit of having cleared away much of the confusion in which this intricate subject was until recently buried, of having discarded a complex, misleading, and useless terminology, and of having made it possible for persons not investigators or *experts to form a tolerably* accurate and clear conception of the anatomy of the pulmonary parenchyma and *of its relations to the larger air passages*. But even yet the reform is incomplete. It is not enough to have swept away as mere subjective expressions such *terms* as primitive and secondary lobules, lobulettes, air sacs, and the like. *Others supported by great authority remain*; and, whilst either having no correlative facts, or conveying inaccurate representations of those really existing, they suffice to keep obscure that which is simple, and to render barren or fertile only in error the application of anatomical facts to pathological *processes and* practical work.

Schäfer, for example, speaks of bronchia, bronchioles, or respiratory bronchial tubes, of their endings in enlarged *completely sacculated alveolar* passages, and of the giving off *from them of blind ramifications or infundibula enlarged* towards their extremities and everywhere closely beset with air cells. Elsewhere he says: "At the end of the respiratory *bronchioles, near the* passage of the infundibula, all the cells which line the wall *of the tube are of the non*-ciliated pavement variety. But the air cells themselves, both those which are scattered over the respiratory bronchioles *and those which cover the infundibula*, as well as intermediate portions of the *infundibula*, which *occur here* and there between the air cells, possess an epithelium of a peculiar character."

Now, in this quotation, even with the *help of the context*, it seems to me *impossible to find a clear, connected*, and exact account of the *terminal* air passages *and of* their relations to the *pulmonary* alveoli. And this impossibility, as I view it, lies less in any error committed by this distinguished anatomist than it does *in the multiplication of* distinctions, forgetfulness of the archetypal idea of a respiratory organ and the use of terms which *are at once* confusing and useless. There are two necessary—and, as it happens, they are the *only unerring*—guides to the complete and accurate understanding of the structure of an adult organ. The first is the study of its comparative history throughout the animal series; and the second is the study, from beginning to end, of the course *of its own development*. Investigated after this manner, the difficulties *encountered* in understanding the minute anatomy of the lung disappear; *and the relation* of the air passages to the alveoli become so clear and easy of apprehension *and expression*, that the use of many and complex terms is neither *necessary nor justifiable*. The primitive type of a lung is a cylindrical tube, *the sides and end of* which are portioned out by delicate membranous septa into shallow cubical *spaces, not communicating* with each other, but only with the common *lumen* of the tube round which they are arranged. If one will *imagine a corridor* with open cubicles fully occupying not only each side, but the *further end, the* floor, and the roof; if one will also imagine that no free *space is left between the cubicles*, that they *fully occupy* the sides, roof, floor, and end of the corridor, that they do not communicate with each other, except through the corridor around which they are arranged; that the *corridor imagined* is surrounded without loss *of space* on every side by corridors and *cubicles* similarly arranged; *that all these corridors* lead outwards to the exterior of the house of which they *form a part*; *that, as all these* corridors *run outwards*, they are joined by others without enlarging through the junction; and that at first the corridors are so short as *to have only* a single or double row of cubicles, whilst further outwards they have *three, four*, or even more,—*if you will imagine* all these things, you will be able to frame a sufficiently clear and *accurate conception* of the simple way in which the pulmonary alveoli are *connected* with the pulmonary air passages, and these with one another.

To describe the relation of the air *passages to* the alveoli in a more formal and literal manner, we may take a lobule as the *subject of description*. Each lobule, more or less conoidal in shape, *surrounded by areolar* tissue with all its usual contents, and penetrated at its smaller end by the *lobular* bronchus and by bloodvessels, lymphatics, and nerves, constitutes, as we know, a miniature lung. As soon as the terminal bronchus enters the lobules, *it divides* and subdivides with *increasing* rapidity and but small diminution of size, *until the dividing or branching* process is brought to an end at the *circumference* of the lobule. At its entrance into the lobule the lobular bronchus is but in the second and third divisions, which diminish in size, the walls are alveolated throughout, and the direction is constantly changing. In the terminal portions of the air tubes or passages which do not diminish in size the division is extremely rapid, and the end of each passage is formed by its abrupt closure just beyond a final division. It is this fact which, when a section of lung, including the pleura, is examined from the deep surface, has led to the notion that the terminal passages or tubes form dilatations or sacs at their blind extremities. Fortunately, sections and dissections parallel to the long axis of a passage demonstrate this notion to be incorrect. If this view of the relation of the air passages to the alveoli be accurate, and long study of the subject makes me somewhat confident about it, there is no need for a complex and copious terminology. It will be enough to speak of the lobular bronchus, of the intralobular bronchi or bronchioles, of the inter-alveolar passages and of the alveoli.

---

[1] Quain's Anatomy, vol. ii., p. 514.

The alveoli are almost always spoken of as being hemispherical or vesicular; and their relation to the air passages is often illustrated by reference to a racemose gland or to a bunch of grapes. Both the description and the illustration are alike erroneous and misleading. It is true that under forced inflation, and as a result of injection and of other manipulations, the alveoli do exhibit occasionally a distantly hemispherical shape. But this is abnormal. Lying on the walls of the terminal passages, varying a good deal in size and somewhat in shape, but fairly uniform in depth, they can best be described in the main as irregular cubical spaces. A single layer of a honeycomb rolled into a cylindrical tube and closed at one end by another single layer, the cells of both looking inwards, would illustrate better than anything else that I can remember the relation of the alveoli to the inter-alveolar passages. By carefully inflating and drying a portion of lung, and examining sections of it made at varying angles to the pleura under an inch objective attached to a binocular microscope, the statements now advanced with respect to the relation of the alveoli to the inter-alveolar passages may be easily corrected or confirmed by any competent observer. These remarks on certain points in the minute anatomy of the lung have led me from the main subject of inquiry further than I intended or desired. I excuse myself on the ground that an accurate and adequate knowledge of this subject is essential to a just understanding not only of pathological processes, but also of those respiratory sounds which we employ in the diagnosis of disease.

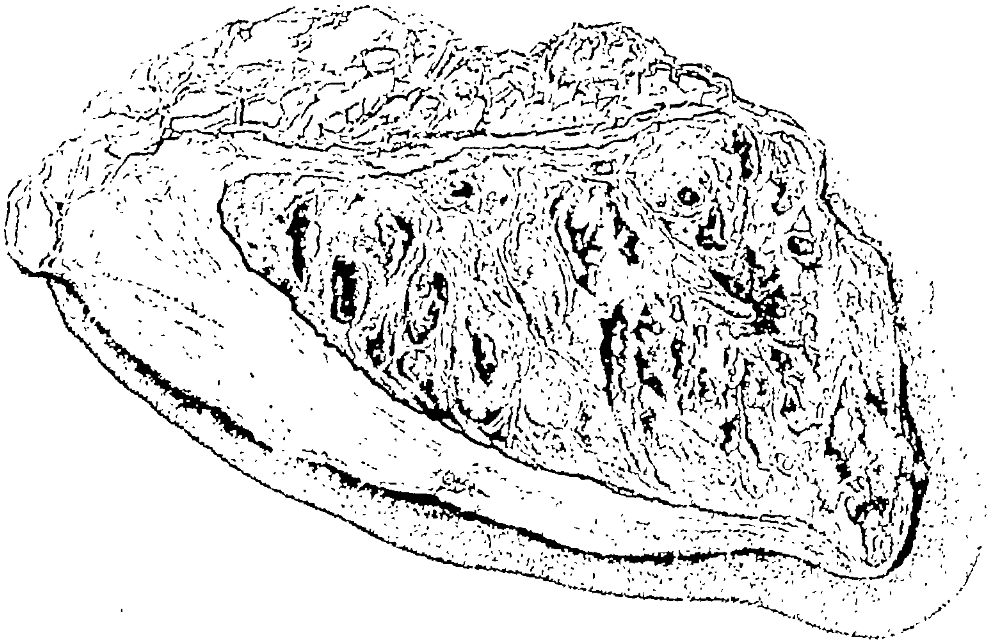
If a little freshly drawn blood is dropped upon a glass slide, permitted to clot, decolourised by gentle washing, and submitted to microscopic examination, three things and their mode of combination will arrest the attention of the observer: a basis substance arranged by wrinklings or foldings into varying sized areolæ, a faint and close network made up of minute molecular-looking fibres, and a small number of leucocytes. The fine fibrillar network will be seen to occupy the spaces enclosed by the areolæ of the basis substance. The leucocytes imprisoned in the basis substance, or in the fine fibrillar network, and undergoing some granular change, appear to be shooting out in all directions protoplasmic processes, and to be engaged in textural development. Examining such a specimen without any knowledge of its nature, it could be easily mistaken for a delicate glioma, and would be unhesitatingly received as a conclusive example of the development of fibrous tissue from leucocytes. But a further critical study of such a specimen will make it certain that no such development is taking place; that both the areolar basis substance and the fibrillar network are formed directly from the liquor sanguinis; that the leucocytes and their processes are in the way of degeneration; and that, whilst they and the fibrillar network will melt into a granular débris, the basis substance will remain unchanged.

I have related this experiment to show how easily one may be deceived by appearances when they run along the line of one's ideas, and how much care is needed in interpreting the changes which occur in recently exuded lymph. In this matter three structural elements are to be found: a fibroid basis substance, fibres, and cells. The latter are either migrated leucocytes or proliferating connective-tissue corpuscles; and it is held that from one or other, or both, the fibroid substance and the fibres are developed, and that the idea of the direct formation from an exudation of [illegible] fibroid tissue must be definitively abandoned. [illegible] the fibres formed in some kinds of lymph this [illegible]ubtless correct; but in respect of the fibres formed in at least one kind of lymph about to be mentioned no conclusive evidence has been adduced. In those exudations which consist of a fibroid basis substance and imperfectly formed white fibrous tissue, this theory cannot justly be maintained.

It is true that there are present in them leucocytes, and sometimes a few fusiform cells; but it is equally true that they do not exist in such numbers, nor show such changes of transition into fibroid materials as would warrant the inference of an exclusively causal relation between them. In such instances, as in the instance of the blood-clot, one may fairly hold that the fibroid elements have been directly formed out of the exudation, and that the cells present therein have taken at least no structural share in their development.

Leaving these collateral considerations, I proceed now to consider the chief forms of exudation produced in the course of primitive dry pleurisies. These exudations may be classed under three heads: the fibrinous, the croupous, and the proliferative.

The fibrinous exudation is characterised by the scantiness of its cell forms and its permanency; the croupous by the abundance of its cell forms and their rapid degeneration; and the proliferative by the abundance of its cell forms and the rapidity and variety of their structural developments. In no case does any one of these forms constitute the entire exudation; but in every case one variety predominates and determines the characters and the course of the changes which ensue. In its early stage the fibrinous exudation consists of membranes more or less extended and more or less thick, which can be detached from the pleura without apparent injury to its epithelial surface. This membrane is greyish, sometimes semi-transparent and elastic, but friable. It does not often adhere to the costal pleura, and it is more frequently found over the upper than over the under part of the lungs; indeed, its most frequent seat is around the summit of this organ. It is composed of a basis substance studded with moleculo-granular matter, shaped into rude areolæ or differentiated into bands of imperfectly formed fibrous tissue, and it contains embedded in it a few epithelial cells, some oat-shaped nuclei, and here and there a nucleated fusiform cell. Sometimes the exudation presents the appearance of an irregularly honeycombed or reticulated membrane, in the meshes of which there is found a yellowish, glutinous fluid, clotting on exposure to the air. In this fluid are found amorphous flakes, leucocytes, and red blood-discs. The structural constitution resembles that of the smooth membranous exudation; but it cannot be so easily removed from the pleura, and whereas the subpleural areolar tissue is in this instance congested, swollen, and infiltrated with a fluid containing many leucocytes, it is in the former instance apparently little if at all affected. At a later stage of its existence this fibrinous exudation becomes denser, harder, tougher, extends into the pleural matrix, and now, opaque and yellowish, cannot be detached without injury from the pleural surface. The subjacent pulmonary alveoli are for the most part little affected, but here and there their walls are thickened [illegible] without apparent proliferation, and their cavities contain a [illegible] fibroid substance, with epithelial cells and leucocytes embe[illegible]dded therein. At a later stage, however, when the fibrinous exu[illegible]dation invades the lung, further changes take place. This invasion, when it takes place, moves in the first instance along the lines of the interlobular fissures, and only at a later period steals along the bloodvessels into the alveoli. In well-marked cases three striking naked-eye changes slowly appear in the wake of this invasion. The interlobular areolar tissue of the affected part is converted into thickened and indurated bands, which, in some instances, contracting and compressing the lobules, give rise to the appearance, rather rare, of a true pulmonary cirrhosis. In the second place, portions more or less extended of the pulmonary parenchyma become solid, hard, tough, dark, and creak under the knife, which cuts them with difficulty. And in the third place, along the course of the fibroid invasion, adjoining the consolidations and at various parts of the summit and free margins of the lung, there are tracts or patches of vesicular emphysema. In the summit of a lung in which limited tubercular growths have undergone fibroid substitution, all these changes, thickened pleura, the fibrous bands, the small consolid and the emphysematous patches, will be found side b In addition to these changes, others less obvious wi found upon close examination. One of them is thick of the adventitia and intima of the pulmonary arterie



the growth from the intima of minute fibroid nodules, which sometimes fill the cavity of the vessel. Another change is thickening of the alveolar walls, with the development therein of free nuclei, not apparently engaged in tissue development. A third change is the appearance in the fibrous bands, chiefly at their intersections, of small fibrous nodules, which resemble and are considered to be true grey granulations or tubercles. But neither the structural characters of the nodules nor the history of the patients in whom they are found justifies this interpretation. They are composed of a fibroid basis substance, having embedded in it numbers, never large, of small free ovoidal nuclei, a few nuclear fibres, and rarely a little elastic tissue. Each consists of one mass, and not of several masses; it does not, as far as I know, contain giant cells; and it never undergoes the cheesy change. Akin to these little nodules, there are sometimes found in cases of long standing, where there have been repeated exudations, larger lumps or flattened masses of like characters connecting the visceral with the parietal pleura, and looking like growths, from which it is not always easy to distinguish them.

The pleura, once the subject of fibrinous exudation, is liable to fresh attacks of inflammation, and to the formation of new membranes, superimposed upon the old. These new layers, although resembling each other in structure, are never completely fused into one, and on section can be easily distinguished. Between the layers there are left spaces, of various sizes, filled with a glutinous fluid, containing epithelial cells, leucocytes, and a few fusiform nuclei. These spaces are coated with an *interrupted* epithelium, and distantly resemble lymphatic sacs. This is the form eventually assumed by the reticulated fibrinous exudation when it is permanent. When only a single thin layer of this fibrinous exudation exists, vessels are not found in it. Even when there are several layers, vascularisation, as compared with the proliferative exudation, is exceedingly scanty; and it seems probable that the development of new vessels takes place rather by channelling and differentiation than by development through the medium of protoplastic cells. Lastly, this form of exudation is characterised by the scantiness of its cell constituents, by the slowness of the changes occurring in it, by its persistence, by its freedom from complication with caseous consolidations and bronchial dilatations, by the lines which it follows in invading the lung, by the rarity of its disintegration thereon, and by the insignificance of its effects upon the general health.

The croupous, or, as it was originally named by me, the corpuscular exudation occurring in primitive dry pleurisies, differs in many ways from the fibrinous on the one side and the proliferative on the other. It occurs for the most part at the middle and lower parts of the lung; it is yellow, soft, thready, unplastic, and full of fluid, containing multitudes of degenerating cells, hyaline globules, blood-discs, amorphous flakes, fragments of granular fibres, granular débris, and countless micrococci. Sometimes, *without* the occurrence of pneumothorax, these accumulations escape by means of minute openings in the pleura, through the lung, and the patient recovers. A single exudation, examined more closely may be divided into three parts. The first is an opaque, yellowish, and friable membrane of varying thickness, incapable of detachment from the subjacent pleura, with which it is apparently organically incorporated. The second is a loose, open, soft, areolated pseudo-texture, infiltrated with fluid. The third, occupying the free surface of the exudation, consists of incohesive, soft, fringe-like processes, which often break on handling. There is seldom any strong adhesion between the costal and the pulmonary pleura. When the exudation is very abundant, and occupies a considerable space between the visceræ and parietal pleura, circumscribed portions of it are sometimes found broken down and occupied by a fluid resembling pus. For the most part this fluid is not pus—not a fluid holding in suspension spherical globules of uniform size, structure, and mode of response to reagents; but a fluid holding in suspension disintegrating leucocytes and epithelial cells, granule cells, and hyaline spheres, oat-shaped nuclei, and broken fusiform cells, fragments of fibres, and granular débris.

The lung adjacent to the inflamed pleura is always affected to varying depths and in different ways. All the alveoli are congested, and contain desquamated epithelium and leucocytes. A few, but in my experience always a few, groups of alveoli are found in a state of hepatisation. Larger and much more numerous groups of alveoli are in a state of caseous consolidation. In the subpleural areolar tissue, in the interlobular fissures, and occasionally at the entrance of the vessels into the apex of the lobule, small yellowish nodules are seen, and may be commonly traced to lymphatics, from the proliferation of which, or of their contents, the nodules appear to arise. They are composed of an adenoid reticulum and of areolæ of common fibrous tissue, in the meshes of which are found masses of lymph-corpuscles, free, rounded, or oval nuclei, nucleated fibres, and numerous multi-nucleated cells in a state of active endogenous proliferation. Resembling in some ways tubercular nodules, they are often declared to be tubercles.

A close examination of the outer surface of one of the earliest formed layers of exudation will sometimes bring to light the existence of two sorts of minute openings. The one are stomata, chalice-shaped cavities, with epithelial lips and linings leading into lymphatic spaces. The other are minute openings, the mouths of burrowing and sometimes branching tunnels, which occasionally can be followed into the pulmonary alveoli. It is not improbable that when a croupous exudation melts, it sometimes makes its way through these tunnels into the lung, and is thence discharged. In a case which I recently attended with Dr. Barnes and Mr. Merriman, a puerperal pleuritic croupous exudation led, by melting, to the formation of three small encysted empyemas. Paracentesis having been considered inexpedient, the pyoid collections were left to nature. After a week, in the neighbourhood of one of the sacs there was heard a coarse moist crepitation; a few days later the crepitation became a bubbling rhonchus; and shortly afterwards some ounces of a pyoid fluid, quite different from genuine pus, were expectorated. The same procession of events attended the emptying of each sac. Meanwhile there was no single sign of pneumothorax; and although the thoracic walls corresponding to the empyemas were bulged, there was no displacement of the heart or of other organs. The patient is now completely convalescent. Sometimes this pleuritic croupous exudation has a constitutional origin, and then the affection may be bilateral. With a low capacity for organisation, this exudation exerts at times a considerable influence for evil on the subjacent lung. The effect consists sometimes in disseminated caseous or lymphoid consolidations, sometimes in fibroid changes, and sometimes, although rarely, in small excavations or in bronchial dilatations. Basic lung disease akin to that described by Mitchell Bruce and others now and then arises in this manner. The tissues of this exudation are, in at least one respect, remarkable. When the case pursues a favourable course, the exudation is for the most part entirely absorbed, and I have once or twice learned from examination after death, that within a few months of an attack, every vestige of its presence has been removed. Now and then the fluid part of the exudation is absorbed, and the residue, becoming dry, undergoes caseation. In this condition calcareous plates and particles are occasionally deposited in it, and the patient becomes subject to obscure and often recurring attacks of pain.

The proliferative pleuritic exudations which I now proceed to describe are of more frequent occurrence than the other two, more varied in their course, and more enduring in their larger issues and effects. They are still further distinguished in their origin from fibrinous and croupous exudations; for whilst the latter are preceded by the phenomena of inflammation, and accompanied by an abundant fluid exudation, the former sometimes arise, increase, invade the lung, and undergo textural changes unaccompanied by any other phenomena except those belonging to a slow and simple textural growth. Indeed, this variety of proliferative exudation often passes almost imperceptibly into pleural new growths, and further on I shall have to advert to several cases of this kind. Beginning in the subpleural connective tissue, and accompanied from the first by active cell proliferation, this exudation passes through the pleural matrix in two ways. Accompanied, as is usually the case, with an abundant fluid plasma, the exudation reaches the pleural surface without apparent breach of continuity. Unaccompanied by any such fluid, proliferating cells arranged in pointed groups push their way through the pleural matrix, and, making breaches of continuity therein, reach the epithelial surface, spread rapidly thereon, and unite to form a continuous proliferating neo-membrane, which at various parts differs in aspect, consistence, and thickness. The even membranous form, however is not always maintained. Sometimes, when the masses of cells and fibres arfounded on concurrent clinical and pathological observations, we shall have to re-classify bacillary affections in such a manner that, whilst the bacillary supremacy remains acknowledged, the differentia giving them permanent and real, although subordinate, individualities shall be formulated and maintained.

The homoplastic are not, however, the only changes which occur in the exudations of primitive dry pleurisies. Metaplastic changes arise; and out of the simple structural elements of the proliferative exudation are developed such changes of form and of arrangement as constitute, within certain limits and conditions, fibrous, syphilitic, leprous, and other growths. But neither upon them nor upon the arger considerations which they suggest have I time at present to dwell. Reviewing the pathological changes brought about by primitive dry pleurisy, it becomes plain that they may be properly arranged as so many pathological entities in four divisions: the neoplastic pleuritic membranes, the fibroid lung, the bronchiectatic lung, and the fibroid phthisical lung. The complete and adequate understanding of these pathological changes is undoubtedly important, but it is not sufficient; for, although sometimes they are the direct results of injury coming from without, they are in the majority of instances the anatomical renderings or structural expressions of underlying states of system which are of the essence of the disease, and demand he first and chief attention. To these dynamic states we hould now naturally turn in order to learn how, by their ntegrations and disintegrations, their ceaseless groupings and shifting equilibria, they originate, maintain, transfigure, and end the varying structural forms which are the only visible manifestations of their presence. Such an inquiry, however, would lead us into the realms of speculative pathology, and leave out of sight the clinical uses of our anatomical study. To this humbler task let me proceed; and in trying to show that the pathological entities have corresponding clinical autonomies, let me endeavour to turn the knowledge of this relationship into use for the daily business of our lives.

Before proceeding with this task it may be useful to state more formally than I have done the position which, at present, the bacillary hypothesis seems to held in the scientific mind. In the first place, it is held that there is nothing autogenetically distinctive in the structure or form of a tubercle; that what alone makes a growth tubercular s the presence in it of the tubercular bacillus; that tubercular bacilli are present in all tubercular and scrofulous products which are thus in nature essentially identical; and that their absence, at some given time from such growths, s not a proof that the bacilli have never been present, but merely that they have been destroyed by some curative change in the tissues invaded by the parasites. In the second place, it is held that the inoculation of certain healthy animals with the tubercular bacilli is followed invariably by an eruption of acute general tuberculosis, and that the tubercles thus begotten, as well as their successors for generations, remain inoculable and virulent. In the third place, it is held that the inoculation of healthy animals with substances not containing tubercular bacilli are invariably infructive, or fructive only in products which are either sterile or beget only local effects. In the last place, it is held that the true and sole causal agent of tubercular, scrofulous, and allied diseases is the tubercular bacillus; and that the various forms which they assume, and the different courses which they follow under the irritative action of the bacilli, are accidental results due to local peculiarities of structure, the influence of external circumstances, and the constitutional tendencies of the invaded organism.

But whilst some of these contentions are proved, and some are probable, they are neither universally nor unconditionally accepted. There is a minority of persons, and I place myself among them, who contend that the exclusively causal agency of the bacillus, although extremely plausible, is not conclusively proved; that a greater number and variety of experiments of control are yet needed to satisfy a just scepticism; and that, even now, in the affections discussed, there must be admitted the existence of bacillary and of non-bacillary consolidations; and therefore of a bacillary and non-bacillary phthisis.[3]

At the present time, when men are still in the fervour of their conversion to the brilliant experimental discoveries of Koch, such protestations of a sober judgment will regarded as unpardonable sins, and punished with suita severity. Well, the sufferers under chastisement must co sole themselves with the reflection that it is only th whose judgments have been disturbed by emotion, or w have never sounded the deepest depths of knowledge, who have not passed through the perils of its subtl casuistries, that are exempt from difficulties, or doubts, fears; and that for the most part truth is won, not by th who rush impetuously forward in its pursuit, but by th who, with open and eager mind, are yet in patience conte to "labour and to wait."

Croonian Lectures

ON THE

HYGIENIC AND CLIMATIC TREATMENT O CHRONIC PULMONARY PHTHISIS.

Delivered at the Royal College of Physicians,

By HERMANN WEBER, M.D.,

PHYSICIAN TO THE GERMAN HOSPITAL.

LECTURE II.

Curative Treatment.—Relation of Doctor and Patient. 1. Diet: Defective Digestion; Raulin's Researches o Mineral Substances; Milk; Times of Meals; Cures o Phthisis; Alcohol.—2. Air and Ventilation; Open-ai Treatment; Defective Arrangements for the Treatmen of Phthisis in General Hospitals; Brompton and Ventno Hospitals; Necessity for numerous Small Hospitals fo Phthisis in the Country.—3. Exercise.—4. Managemen of the Skin; Clothing.

Mr. President and Gentlemen,—With regard to th curative treatment of phthisis, the main points which w ought to aim at are: improvement of the general nutritio of the body, or, to use Dr. Beale's expression, of the "bi plasm"; restoration of healthy respiration and circulation i the lungs; limitation of the existing disease; preventio of fresh outbreaks or fresh infection. The principal mean to obtain these ends are: adequate supply of food; abundance of pure air by night and day; regulated exercise strengthening of the skin; healthful occupation of th mind. We might perhaps say, in other words, that w must aim at improvement of the tissue change by increase supply of pure air and nutritive material to the cell and tissues, and by perfecting the elimination of used-u material; but we must, at the same time, keep off impur air from the diseased spots. I shall discuss the hygieni treatment under the following heads:—1. Food. 2. Air and ventilation. 3. Exercise and rest. 4. Bathing and management of the skin. 5. Climate.

Allow me, however, Sir, before I enter into these point to say a few words on the relation of the doctor to the consumptive patient. Shall the doctor frankly tell the latte that his disease is phthisis? It is still the opinion of many eminent medical men that we should, as a rule, not do s As long as phthisis was considered an incurable disease there may have been reason for such concealment, but now as we know, and can tell our patients, that phthisis is a curable disease, I think the patient ought to be informed of his condition, more or less according to the individuality; and as far as my experience goes this has a salutary effect. The patient is more ready to co-operate with the doctor and to bring the great and long-continued sacrifices, for h becomes aware of his own large share of responsibility. have already alluded to the circumstance that intelligenc on the part of the patient and his friends is a great hel towards recovery in phthisis, and that want of judgment o insight into the nature of the illness, and of the manifol dangers, and into the means of cure, renders the prognosis less hopeful, unless we are able to place the patient unde the strictest superintendence of a judicious doctor, or, still better, in a health establishment under the control of a resident medical man and his assistants, or into a well-arranged special hospital.

---

[3] De La Phthisie Bacillaire, par le Professeur G. Sée, 1884.

1. *Diet.*—All those who have been successful in the treatment of phthisis have paid much attention to the question f food. Sir Risdon Bennett and many other physicians ave shown that by "feeding" alone great service can be one. If the popular idea were correct, that the appetite d digestion of consumptive patients are specially good, it ould be more easy to cure phthisis; but the rule is rather e reverse. The poorer the blood and nutrition of the cells d tissues, the greater therefore the want—the less is often eir desire for food. The appetite is not rarely capricious, d the digestion is apt to be disturbed. It happens also at patients object to the diet ordered, and it is therefore metimes necessary to tell them plainly that without their ordial and constant assistance in this matter they have no hance of recovery. At the same time, however, the fancies f the patient ought not to be disregarded. The food which e desires, if it is in any way permissible, ought to be proured for him. It ought to be as varied as possible, and he cooking and serving of meals ought to be nice. The xample of others is mostly very useful; and this one point in favour of special establishments and ealth-resorts for phthisis, as at Goerbersdorf, under Dr. rehmer and at Falkenstein under Dr. Dettweiter. I ave also seen at Davos and St. Moritz patients in mpany with other patients eat and drink, with regard quantity and quality, what they would never eat their own rooms alone, or with members of their amilies. Though it is impossible to lay down fixed rules or all cases, one rule is almost general—namely, that those uffering from consumption ought to take the amount of od required by frequent small meals, and not by only two rge meals, as in French, or three meals, as in German and wiss hotels. This is one of the reasons why ordinary otels are in general not adapted to the treatment of active hthisis. In addition to breakfast, lunch, and dinner, there ught to be four supplementary meals—namely, early in e morning, between breakfast and lunch, between lunch d dinner, and at bedtime. Before passing in review me of the principal articles of food, I wish to direct tention to the possibility that there may be important lations between the life of the tubercle bacillus and e quality of the food that we take, especially the saline aterials which enter into the composition of the blood, e cells, and tissues. A short time ago I had the pleasure listening to a suggestive lecture delivered by Dr. Vivian oore at the Society of Arts, in which he related the sults of most instructive researches by M. Raulin on e growth of the Aspergillus niger. A short account of ese researches is given in Dr. Duclaux's "Handbook on ermentation," prepared for the International Health Exhibition in 1884. After much trouble, Raulin found the folwing liquid the best nutritive medium of the aspergillus. is known as Raulin's liquid:—Water, 1500 grammes; sugar ndy, 70 grammes; tartaric acid, 4 grammes; nitrate of ammoia, 4 grammes; phosphate of ammonia, 0·6 gramme; carboate potassium, 0·6 gramme; carbonate magnesia, 0·4 gramme; ulphate of ammonia, 0·25 gramme; sulphate of zinc, 0·07 ramme; sulphate of iron, 0·07 gramme; silicate of potassium, 07 gramme. By sowing the spores on this fluid, two ops of aspergillus can be grown, which weigh together grammes; but if we prepare the fluid without the otassium, the gathering will dwindle to 1 gramme only; e crop has, therefore, fallen to $\frac{1}{25}$th of what it was. It ill fall to $\frac{1}{200}$th if the phosphoric acid, and to $\frac{1}{150}$th if the mmonia, be withdrawn. The withdrawal of the zinc would duce the crop to $\frac{1}{10}$th of what it was in the complete quid—in other words, would bring it down from 25 grammes o $2\frac{4}{10}$th grammes. Duclaux points out that the zinc—in veight only $\frac{1}{50000}$th of the fluid—increases the crop of the lant by 700 times its own weight; and he further states that, $\frac{1}{1600000}$th of nitrate of silver be added to the nutritive uid, the vegetation stops abruptly. We learn from this at microbes require mineral food in the same way as lants and animals do, and if we knew exactly which ineral substances the tubercle bacillus requires, and could, vithout harm to ourselves, deprive our blood and cells and issues of these salts, by abstaining from food containing them e should deprive the bacillus of the means of existence. he investigation of these matters, however, is very difficult. t is not easy to construct the best nutritive fluid for each icrobe. It can only be obtained by a series of methodical esearches. When the best artificial medium has been reated, it must be first ascertained that the result of the owing of the spores is always uniform, otherwise the result of the withdrawing of certain elements cannot be calculated. It is further evident that a study of agents impeding or destroying the growth may also become very important. With regard to the different articles of food, Dr. Bidder, of Berlin, points out from several papers by Dr. Bunge, of Dorpat, that the food of carnivorous animals contains a larger quantity of soda and smaller of potash than that of herbivorous animals, and he reminds us that carnivorous animals are on the whole less subject to tuberculosis than herbivorous animals. If it could be proved that the potash salts are more conducive to the growth of tubercle bacillus than soda salts, articles of food containing excessive properties of potash ought to be taken only sparingly.

Milk is regarded by the majority of medical men as one of the best articles of food in the treatment of phthisis. It contains all that is required by the body, and the mineral matters in the best proportion. It is less irritating than other nourishing kinds of food, and is more easily digested. There are differences in the quality of the milk of different animals, and also of the same animal, according to the food consumed by it, and other influences; but when merely speaking of milk we mean cow's milk. The dangerous substances which can be introduced by it, as the fever poisons and the tubercle bacillus from cows affected by the disease, and principally those with diseased udders, are, so far as we know, destroyed by boiling. We ought therefore, unless we are perfectly sure about the milk-supply, always to recommend the milk to be boiled. Patients often say that milk disagrees with them, but I have only rarely been able to acknowledge this statement as correct. In some cases where there is a tendency to diarrhœa or sickness, or acidity of the stomach, it is necessary to dilute it with from one-third to one-sixth of lime-water, which often exercises a soothing influence on the mucous membrane of the intestinal canal, and may, besides, help to bring on the cretaceous change in caseous deposits. In other cases, especially where there is constipation, the addition of Apollinaris or natural Selters, or Bilin water, is useful; in others that of barley water; in others, a small quantity of coffee, tea, or cocoa renders the milk palatable to persons who have a dislike to the taste of pure milk. In many instances the addition of rum or cognac promotes the digestibility of the milk, especially in persons accustomed to stimulating food, including much alcohol, but this addition ought to be made only under the guidance of the doctor. The quantity of milk suitable to different invalids varies very much, indeed, in the same person at different periods of the disease, and also according to the amount and quality of other food consumed. I generally advise from one and a half to three pints in twenty-four hours, but in many cases, especially those complicated with albuminuria, I restrict, sometimes for weeks, almost entirely to milk and milk food.

I dare not discuss other articles of food in the same way as I have done with milk. Everyone interested in dietetics will find valuable information in the works of Playfair, Frankland, Pavy, and Bauer.

About diet in general I will confine myself to some general rules. 1. To induce the individual to take as much nourishing food as his digestion permits, and to endeavour to increase the appetite and digestive powers by air and exercise, and sometimes by medicinal substances. 2. To give as much choice and variety as can be obtained. 3. To avoid articles of food, or of relish, of inferior nourishing value, if by these the appetite for more necessary articles is diminished, or the digestion of the latter is disturbed. Such articles are, for instance, acids, salads, and especially uncooked acid fruits, sugar, and pastries, a list which might be largely increased. Potatoes ought to be taken only in very moderate quantities. They contain much potash in proportion to soda, and experience shows that the exclusive, or even preponderating, use of potatoes favours scrofula.

I have mentioned before that in the majority of ordinary cases of phthisis, except the very chronic and arrested forms, it is better to take the desirable amount of food in frequent small meals than in two or three large ones. I am in the habit of recommending a plan of the following kind, with many modifications according to circumstances:—At seven o'clock or earlier, while still in bed, a cup of milk by itself, or with a dessert- or tablespoonful of cognac, or with lime-water, or with a small quantity of tea or cocoa and a small piece of bread-and-butter. At half-past eight or nine, after dressing, breakfast of milk, with some slightly stimulating addition, as tea, coffee, or cocoa; bread-and-butter, or bacon, ham, or fish. At eleven, a tumblerful of milk or koumiss, or sometimes a cup of broth or beef-tea, or a sandwich and a glass of wine. At one or half-past one, a substantial meal of meat, or poultry, or fish, or game, with fresh vegetables, some light pudding or cooked fruit, and a glass of wine. At four o'clock, a glass of milk or koumiss, or a cup of tea or coffee with much milk, and some bread-and-butter or plain biscuits. At seven another substantial meal similar to that in the middle of the day. At half-past nine or ten, on going to bed, a cup of milk, or bread-and-milk, or milk with some farinaceous food, as Hart's, Liebig's, Nestlé's, or Mellin's. At this time, if there are night sweats, the addition of a tablespoonful of brandy is very useful.

In cases of considerable pyrexia it would be injudicious and impossible to give as much solid food as in chronic non-febrile or nearly non-febrile cases, but it is necessary to give as much easily digestible food as the patient can digest. Our aim ought to be somewhat to check the waste, and to replace by food the increased waste. Here alcohol is of great use. Milk is often not digested in its natural state, but it must be tried peptonised and diluted with pure water, aerated water, or, still better, with barley-water or thin gruel. Chicken broth, veal broth, beef-tea, and gelatinous substances are in these conditions most useful; while in health, and in the non-febrile consumptive cases, they ought not to take the place of the more solid proteinaceous substances. In most cases of phthisis it is desirable to introduce into the system a fair amount of fat, and this can often be done better in the shape of bacon, fresh butter, and milk and suet, than in the form of cod-liver oil, though the latter, too, is most useful. There are some popular "cures" of phthisis into which milk or different kinds of fat, assisted by open air, enter largely. You all know the milk cure in the various mountain districts, from the time of the Romans to the present day; the koumiss cure in Tartary. I remember also the buttermilk cure in some German villages, and have often heard that in the American prairies consumptive patients are cured by consuming large quantities of the bone marrow of the buffalo. Many years ago, when assistant at a clinic at Bonn, two of my poor consumptive patients left me to be cured in a neighbouring village by taking three times a day or more frequently a large plateful of a kind of porridge prepared of dog's fat and rye meal, and certainly their improvement was most remarkable. But they had exchanged at the same time their in-door town work for out-door country work. All these cures have two points in common: first, food rich in fat and proteinaceous matter; and, secondly, out-door life.

I cannot close the chapter on food without entering into the debated question of alcohol. Much as I am convinced that in health alcohol is rarely necessary, in phthisis, especially in the febrile stages, experience has convinced me of its great usefulness in the majority of cases so long as the kidneys are sound. It acts as respiratory food (Binz) and limits the waste of tissue. Brehmer, Spengler, Unger, Rüdi, Volland, and Dettweiler use it largely; Austin Flint, too, is a strong advocate for its use. The quantity and quality required vary very much in different cases. In some cases as much as a bottle, and even three pints, of moderately strong wine, or ten to twelve ounces of cognac or whisky, are taken in twenty-four hours with advantage; in others scarcely one-sixth of this amount; and, again, in others alcohol must be altogether avoided. Alcoholic drinks seem to be specially useful in those cases where a pretty large quantity can be taken without unpleasant excitement or headache; but where, on the contrary, a sense of comfort and increased strength is produced by them, where appetite and digestion are improved, flatulence and indigestion removed, and pyrexia, where it exists, is diminished. Where, on the other hand, they cause throbbing in the arteries, headache, listlessness, flushing, or great excitement, or loss of appetite for ordinary food, they are either unsuitable or can only be taken in small quantities. The doctor must decide by careful examinations whether, and in what quantity, alcoholic drinks are to be given. The quality, too, cannot always be known without trial. In Germany and Austria the stronger Hungarian wines are much liked; in the Alps the red wines of the Valteline; but Madeira, Marsala sherry, Burgundy, good claret, and some pure Italian and Greek wines are likewise useful in many cases, and not rarely beer; cognac and whisky suitably diluted are of great value in cases of weakness. Very often Dr. Dettweiler's plan, to give the amount of alcohol required in very frequent and small doses, is of great practical value.

2. *Air and Ventilation.*—Although it is generally acknowledged that impure air is the foremost cause of phthisis, and although Dr. Henry Mac Cormac, Dr. B. W. Richardson, and others have preached not only this, but also that pure air is the most important means of cure, yet we must all confess that in practice the first principles of air treatment are, with rare exceptions, most imperfectly carried out. Wherever climate permits an entirely open air and tent life is the best help in the treatment of phthisis; but this is not easily practicable the whole year round in our climates, although much might be done in this direction. Fears of the inclemency of the weather are far too great amongst the public as well as the profession. Patients affected with chronic consumption, without or with only moderate and partial pyrexia, ought to spend the greater part of most days in the open air, and ought not to be deterred by a little rain, or mud, or low temperature, or by the fact that they begin to cough when they come out of the close house into the open air. Arrangements ought to be made by which invalids are enabled, warmly dressed, to sit in the open air, sheltered from wind and rain. It is here where the degree of intelligence of the patient forms an all-important element in the chances of success. It is necessary, as I have already stated, to give the patient and his friends an idea of the nature of the illness and the means of cure, and to obtain their intelligent, courageous, and persevering co-operation. The patient must see that though it is more difficult to carry out the open air principles in an inclement climate, that it is yet infinitely more injurious to him to shut himself up in close rooms than to use every possible moment of even an indifferent day to walk or sit in the open air. The improvement of the appetite, the digestion, and the strength, the diminution of night sweats, of restlessness, and mental depression, are in most instances so marked that the invali after some time begins to have confidence, and to feel tha his life is rendered more bearable even if no cure ca be effected. We must always bear in mind that ev in the midst of large towns the air in open places, a even in the streets, is very much purer than within t houses. The researches of Angus Smith, Pettenkofer, a others have shown this with regard to the proporti of oxygen and carbonic acid and other impurities; a those of Miguel with regard to the number of microb in the air at Paris manifest this in a most strikin manner. Their proportion within the wards of t Hôtel Dieu and of the Notre Dame de la Pitié being mu larger than in the Rue Rivoli. As, however, the great part of the twenty-four hours is spent in-doors the arrangements of the house and of the rooms are of the greate importance. The invalid ought to have sunny room sitting- as well as bed-room, for, though the sun does no shine at night, the vivifying influence which it exercises o the air of the bed-room during the day does not disappea at once with the cessation of the sunshine, but las through the night and longer; 2000 cubic feet per head not too much space for each inmate, and by good ventilation the air ought to be frequently renewed by day and night. The temperature ought, if possible, never to excee 62° F.; and the open fire is by far the best producer of artificial warmth; gas ought to be entirely excluded. The be ought to be open on all sides, and the ordinary consumpti invalid ought not to be longer than eight or nine hours bed, even if the body temperature is somewhat raised durin some hours of the day. It is a horrible custom to keep suc invalids during the greater part of the day in bed unless th weakness be extreme. In all diseases it would be a usef subject of discussion when a patient is to be in bed an when not; when he is to take exercise and when to sit o lie still. But in phthisis the long stay in bed, and particularly in the bed-room, is certainly injurious; breathin ventilation of the lungs, circulation, appetite, tissue chang almost everything is unfavourably influenced. In acut forms and stages of phthisis, when there is much feve I do not advise the patient to take active exercise, o to fatigue himself by sitting up during any length o time; but it is certain that pure and fresh air is a necessary, and even more so, than during the non-febril stages. The bed of the patient ought therefore to placed that he receives as much open air as possible withou exposure to actual wind or draught. In summer, and also i winter, weather permitting, a couch or bed ought to be place on a balcony or terrace, or in an open field or garden; th patient ought to be carried to it and properly covered, la there from morning to night, or as long as possible. Som

of my patients have spent during weeks, or even months, a great part of the day in hammocks slung up between trees, with great advantage. The change from the ordinary bed treatment in a close room to this open air couch or hammock treatment is an infinite gain to the patient who breathes more, eats better, is more cheerful, sleeps more soundly, and is less troubled with perspiration. The pyrexia, likewise, often rapidly decreases. I shrink at present from touching the open-air treatment of the poor at their homes, except so *far as they likewise* should be taught to be as much as possible in the open air, and to sleep with open windows; and I may add that I have seen many instances where a change to open-air occupation in all weathers, from indoor work in close workshops or bakehouses, has led to an arrest of disease and recovery. I must enter, however, a little more fully into the treatment of poor consumptive patients in our general *hospitals situated in large towns. There they* have usually only between 800 and 1200 cubic feet of air per head, with ventilation through open windows, which cannot be efficiently carried out without *draught, and is in winter* often sadly neglected. The majority of these patients, even if here *is only moderate* and partial pyrexia, spend the whole, by far the greater, part of every day in bed, which, as I ave already said, ought not to be, excepting in acute cases, stages, or in excessive *weakness; but if, after the subsi-* nce of the pyrexia, they are out of bed standing, or sitting, *walking about in the* wards, they are exposed to draughts, d frequently contract fresh attacks of bronchitis or eurisy, or other illnesses due to chill, and thus take rther steps in their *downward course. Although I have* ways been fond of hospital work, these considerations ave for a long time been a source of worry to me whenever stood at the bedside of my consumptive patients, and in spair I have more than once said that they were in the orst place in the world; and yet the hospital to which I attached stands on an open spot at Dalston, and has all plots of ground attached to it where convalescents sit and walk, while the hospitals in the *interior of* ndon *are* mostly deprived of this advantage. This is, leed, *a subject,* gentlemen, which deserves your serious ught, and I earnestly entreat you, if you agree with me, enlighten the public and to use your influence to procure er accommodation for the treatment of the consumptive ents of the poorer classes. I know that many medical , and perhaps *some* of those whom I have the honour of essing, are not in favour of special hospitals. If the eral hospitals are well arranged for the *treatment* of isis, and situated in good air, *some of my objections* fall e ground, but these favourable conditions are rarely met . Very much better are the arrangements in the Brompton ital for Consumption, especially in the new building, I had the advantage of seeing quite recently with heodore Williams. Each of the three floors devoted to tients consists of a corridor *10 ft. in width,* a large al dining-room, ten wards 13½ ft. high, holding from eight beds—forty-six in all. The average floor space d is 115 ft., the cubic space being 1400 ft. The ventiis maintained independently of the windows and fire-, and supplies 4000 cubic feet per hour to each patient. ir is admitted by numerous openings placed on a level different floors—on the east and north into the gal-, on the west and south into the wards, the greater n being heated by passing over coils of hot-water ; a part is admitted directly. The quantity of hot old air can be modified at will, and the temperature able of being evenly maintained. The foul air is off from the corridors, wards, &c., through extracting built in the walls, and furnished with *openings* at floor eiling. These flues run into large air ducts beneath the which communicate with *four* towers heated by steam forming the exhausting chambers. With these arrange-s *it is possible for patients* to walk about in the corri- or to sit in the central hall and converse with *one* er without being exposed to draughts and chills. It a great pleasure to *see almost all the* patients out of

The drawbacks unavoidable with the situation in lon, especially with *the east* and north-east winds, are rdinary contamination of the air and the *occasional* and the *fair results* obtained show how much good can ne by judicious treatment and arrangement *in* spite of a grave natural defect.

initely more advantage*ous is the* situation of the onal Hospital for Consumption at Ventnor, with which e been *acquainted* for many years past, and which I have lately again visited, under the guidance of Drs. Coghill and Robertson. The Undercliff is so well known to you that I need not give a description of the delightful and healthy situation. The peculiarities of the arrangement are, you know, that the whole hospital is built in blocks for twelve patients each, that each patient has a separate sleeping room of from 1500 to 1750 cubic feet, and in the newest block 2000; that each six patients have a separate sitting-room, *3000 cubic feet space*, and each block (twelve patients) has an additional room in which breakfast, tea, and supper are served, of 3000 cubic feet; that male and female patients *dine separately in large rooms* at the end of the blocks. There are various arrangements for the renewal of air, which, though they would be regarded as satisfactory in *other hospitals*, have not appeared so to the authorities of the institution, so that in the new block, on Dr. De *Chaumont's recommendation*, a supply of 5000 cubic feet of fresh air per head per hour has been adopted, and the fresh air is to be delivered at a temperature of 62° F. *Dr. Hassall has rendered a great service* to the public and the profession by originating the foundation of this hospital. Between the hospital and the sea there is a large piece of open ground for exercise and sitting in the *open air.* The diet of the patients is well arranged; the results of the *treatment are satisfactory*, and the patients are mostly very happy during their stay. What I should like to add are terraces and balconies, on which light beds or couches could be placed for *febrile patients to lie on, and thus to enjoy* the open air; and, further, large verandahs, glass covered, *and with* movable glass doors to be opened and closed at will, so that patients might sit and walk there during wet and windy weather. Further useful additions would be seats with *shelter overhead and on three sides, turnable so* that the shelter might be turned against the wind, and the patients sit there with the whole front open, even in rain and windy weather. I should *also* be *inclined to erect in* suitable places walls with reflecting surfaces, to serve as *shelter* from wind and as *reflectors of the sun's warming* rays. Hammocks would be at times likewise a comfort.

There *are, also, small sanitaria* for consumptive patients at Bournemouth and *Torquay; but the number of beds added* together is almost infinitesimal compared with the number of consumptive patients belonging to the poorer classes. *If* there were a hundred of such hospitals they would *be a fair* instalment of what is required to meet the most necessary wants. I should not recommend large hospitals, but small *ones,* for 80 or 100 beds, with from *one to three* or four patients in each room; with balconies to hold one bed, so that one febrile patient could be moved into the open air, and more than one such ought never to be in the room. There should be *large verandahs for exercise and sitting* in wet and windy weather, shady and sunny seats, seats such as roughly sketched above, with turnable shelter to be used in windy and wet weather; and in other respects *arrangements* similar to those at Ventnor and Brompton. Each hospital ought to have a resident medical officer, and there ought to be ample *room for exercise on level as well* as on rising ground; the neighbourhood of a pine forest would be a farther advantage. They ought to be in the *country or at the seaside,* on account of the greater purity of the air. Even in the suburbs the air is *much purer than* in the interior of towns; thus Miguel found in ten cubic *inches* of *the air* of Montsouri (a suburb of Paris) 7600 microbes; in the Rue Rivoli (in the centre of Paris) 55,000; and a still *much larger* number, as already stated, in the hospital wards, especially in the winter. It would not be difficult to find fairly suitable localities. Surrey, Kent, Berkshire, and Hampshire *have* good sites. On the southern slopes of their pine-clad hills—for instance, between Leith-hill *and* Ewhurst *Windmill*, between East Grinstead, Frant, Wadhurst, and Ticehurst; between Ripley and Cobham; on the Chobham ridges; between Farnborough, Minley, Bramshill Park and Eversley; *near Haslemere, on the* slopes of Black Down and Hind Head. The southern coast and also the south-eastern *offer fair localities,* if care is taken in the selection of the spot with regard to shelter, dryness of soil, *and exercise ground. The* Undercliff, for instance, and the neighbourhood of Bournemouth still possess some not yet overcrowded sites; also Torquay, Sidmouth, Lyme Regis, Dawlish, Hastings, and perhaps Sandgate; on the coast of North Devon and Cornwall and near Llandudno and in Bute good spots could be found. I know, gentlemen, that small hospitals for consumption such as I have suggested are *expensive,* and *that* it would be difficult to find the money, but if you are convinced of the advantage to the patients, and will use your influence, donations and legacies will come in, and in the course of time we shall take a step in the right direction.

3. *Exercise.*—Exercise is one of the most powerful and essential means of cure. It is as necessary as air and food, because it enables the invalid to take both in a sufficient quantity to improve the nutrition by taking up fresh material and removing the waste, and thus to fight a battle with a fair chance of success. Without exercise I should not like to treat phthisis. To take exercise properly requires, however, the guiding hand of the physician; there are judicious persons who can be taught to become sufficiently acquainted with their entire condition and their surroundings to enable them to do neither too much nor too little, but such persons are rare amongst consumptive invalids. In many of them the nutrition of the brain has suffered as much as that of the stomach and lungs and other systems, and their judgment with regard to their own state and their wants is impaired. We ought, therefore, to bear in mind that by far the majority of those suffering from phthisis require constantly to be held by "leading reins," and must be told what kind of exercise to take, how much, and at what times; walking on level, climbing gently, and with measured increase as to duration and steepness. Riding on horseback, skating, and tobogganing are all useful *exercises under guidance, but over-exertion ought to be* carefully avoided, and one mistake often destroys the fruit of months and years of judicious management. Up to a certain point the sense of fatigue is a guide, but not always, for some persons feel fatigue at the beginning of a walk and improve while taking it, and others never acknowledge to themselves the sense of fatigue. The medical man alone can measure the amount of strength, and how it can be maintained and increased by gradually increasing exercise. Climbing is especially useful, as it brings the whole systems of circulation and respiration into play, and leads to expansion of the lungs and thorax and strengthening of the respiratory muscles. Regulated climbing for a course of weeks and months in suitable cases has a wonderful effect on every organ and function of the body; not only respiration and circulation, but the digestion, the action of the skin, sleep, mental power, resistance to changes of temperature, all show the beneficial effect, and we scarcely doubt that this is due to an improvement of Beale's bioplasm, or "living matter," in the cells. Riding on horseback is likewise excellent exercise, exhilarating and accelerating the circulation, and through this the respiration; and it has been the principal means of treatment in several cases of recovery under my observation (Sydenham). Riding on donkeys may, in some localities, be substituted for horse exercise. Tricycling is likewise useful to some invalids. Pulmonary gymnastics—i.e., a methodical deep inspiration, followed, after a pause, by full expiration, practised in pure air several times a day are very useful in chronic non-febrile cases. Well-arranged exercises of the upper extremities materially assist the expansion of the apices and the subclavicular regions. Where active exercise is impossible from great weakness, or forbidden from inflammatory complications, the movement in a Bath chair is especially to be recommended, and by turning the head against the wind it can be used in almost all weathers. Open carriage exercise is likewise good, but there ought to be very little wind, or some arrangement for sheltering from the wind, by having, for instance, the front hood up, and sitting with the back to the horses, which can be well arranged in landaus. Those who have the chance of being moved in a boat up and down a river, or on calm days on the sea, often derive great benefit from this mode of motion. In some cases under my observation well-arranged journeys, in agreeable company, in rowing-boats, or small yachts, or steamers up the Thames, the Rhine, the Main, the Neckar, the Danube, the Isar, the Seine, and Meuse, have had very beneficial effect on body as well as mind, and the latter ought never to be forgotten in phthisis. In some very chronic cases of nerve prostration, with inability to walk and to take food in sufficient quantity, massage can with advantage take the place of active exercise, being a powerful accelerator of tissue-change, and leading to increased breathing and improved circulation. I have as yet had only a few cases in which I have recommended a plan somewhat analogous that of Weir Mitchell and Playfair, though very much nergetic, but with evident advantage on the nutrition, lar and and mental energy. It appears to me, so far experience goes, that there should be no active lung symptoms. The open-air treatment has been combined in those cases with massage, the patients having been placed during a greater part of the day on couches in the balcony, or in the garden. Walking exercise was not allowed during the first part of the massage treatment, but was gradually substituted for it.

4. *Strengthening of the Skin.*—Weakness of the skin is one of the prominent features as well in the tendency to phthisis as also in the developed disease, and ought always to be taken into consideration and remedied if possible. A slight change of external temperature, or exposure to a slight draught or change of clothing is apt to produce chill, which by reflex action is thrown on the lungs; it is also a frequent source of bronchitis and catarrh of the lungs, and also of digestive derangements and a great obstacle to recovery in phthisis. Constant exposure to the open air and exercise are the best tonics for the skin, and often suffice by themselves; but in many cases these must be combined or preceded by the judicious use of hydro-therapeutics. The has never been altogether neglected in England either medical men or the public, while on the Continent neglect has been incredible, and is still so in many localities hence systematic hydro-therapeutics have had their on the Continent; and in the treatment of phthisis Brehmer was the first to introduce them with special *fications,—viz., powerful cold douches to the chest of* short duration. Unger, Spengler, Dettweiler and others have continued and modified this system; Jaccoud, and other French physicians are powerful advocates hydro-therapeutics. Much benefit is no doubt obtained by well-adopted procedures, but they require most management by the medical man. Even the ordina of the skin in itself ought to be guided by the doctor, will not only examine the state of the skin, but also condition of the heart and circulation in all its the degree of reactive power must be cautiously and gradually raised. In great weakness dry rubbing an attendant of one part of the body after another is that can be done; then rubbing the chest with a towel, and dry rubbing afterwards. Later on a very sponging with tepid, and again later with cold, followed by a short return to bed, and a light, breakfast. It requires a considerable degree of force to bear with advantage on rising in the morning sponging of the whole body by cool or cold water, follo by brisk friction as daily practised by the majority of health, and forcibly recommended by J. Henry whose views on the hygiene of phthisis have good influence. A rapid plunge into cold water is in cases of fair reaction the best plan. In others a very shower bath, and, again, in others a tepid bath for a of minutes, followed by a momentary cold shower or into cold water. Many sound hints on bathing and management of the skin may be gathered from the of the "Book of Health," in his article on the skin. CASE OF ANEURYSM BY ANASTOMOS THE HEAD,

TREATED BY LIGATURE OF THE COMMON CAROTID AND SUBSEQUENT LOCAL LIGATION.

BY G. B. FERGUSON, M.D., & G. A. CARDEW, M
SURGEONS TO THE CHELTENHAM HOSPITAL AND DISPENSA

ANNIE S——, aged nineteen, came first under the ob tion of Mr. Cardew at the Cheltenham Dispens November, 1881. She then complained of a p swelling at the back and right side of the head, in also the right ear, which was greatly enlarged. had some swelling about that position throughout th of her life, the first stage having been a nævus, whi never been subjected to any treatment. During the months previous to her seeing Mr. Cardew the tumour had increased rapidly in size, and had frequently burst, severe hæmorrhage in each case ensuing. The patient was a strong-looking girl of short stature, who, with the exception of occasional headaches, had enjoyed excellent general health. On examination, a considerable tumour was visible, evidently a cirsoid aneurysm, otherwise styled aneurysm by anastomosis, extending from the back of the right ear to the occipital protuberance, and extending as high and descending as low as the upper and lower borders of the temporal bone, occupying, in fact, about twenty square inches. The tumour was of a pulpy consistence, and pulsated forcibly, as also did the ear. A loud thrill was audible over it. It was covered with small and thin-walled venous projections, which were the sites of the frequent hæmorrhages. After a specially severe and dangerous hæmorrhage about the middle of December, 1881—she was stated then to have lost about three pints,—her friends and herself became seriously alarmed, and requested the institution of some radical treatment. Accordingly she was shortly afterwards admitted into the Cheltenham Hospital, and came under the care of Dr. Ferguson. There, after due consultation, it was decided that the common carotid artery should be tied, and this was accordingly done in the ordinary manner and with the full Listerian precautions that have been employed by all the surgeons of the Cheltenham Hospital since the year 1876. The operaion presented no difficulty, and calls for no remark save hat, the omo-hyoid muscle passing apparently somewhat higher than is usually the case across the neck, it was easier to secure the artery below than above the muscle; n which former position it was accordingly reached and ied. The ligature was of chromic catgut of medium thickiess, most obligingly sent to Dr. Ferguson by Sir Joseph Lister. And in order that his kindness should not be unnecessarily trespassed on hereafter, we would desire in his place to repeat Sir Joseph's information, that chromicised atgut of identical quality can be supplied by David Marr of Holborn. The patient's progress after the operation was typically satisfactory, there having been neither pain nor any even the most trifling) elevation of temperature. In fact, the ressings were finally removed on the eleventh day after the peration, exposing then the firm cicatrix of a wound that ad evidently healed by first intention. The immediate esult of the operation was the shrinkage, almost to disappearance, of the tumour and the complete cessation of the lsation. It was, therefore, no small disappointment to notice r the removal of the dressings that a slight pulsation again perceptible over the site of the tumour. However, was shortly afterwards dismissed from the hospital in health and spirits and well pleased at the result of the tion. During the next six months her history nted no points of special interest, save that the tumour ne still less noticeable, and that the pulsation remained re. But after this six months' period of quietude a eral circulation succeeded in establishing itself to a someconsiderable extent, and the tumour began again to ine and pulsate somewhat after its former fashion (though less forcibly), and there was even some recurrence of orrhage. This being the case, Mr. Cardew (to whose care ad returned) determined to ligature the tumour subeously. One half of the tumour was accordingly ured with a silk thread in the usual manner, the latter tightly tied. The result was the entire stoppage of pulsation in the part tied. The silk was tightened day for ten days, after which time, when it had t cut its way out, it was removed. This process of ion brought about a notable consolidation of one-half e tumour, and this at the expense of but little pain or uration. Some few days afterwards the posterior pular artery was ligatured on a pin, which had been first ed under it, this step being taken in consequence of its size and evident connexion with much of the remainpulsation. Two months later the other half of the our was similarly ligatured subcutaneously, and again, weeks later, as an additional safeguard, the whole was more subcutaneously re-ligatured. With this last ion the treatment ended, almost complete obliteration e tumour having been effected, with an entire removal e hæmorrhagic tendency; and on inspection of the nt on March 7th, 1884, and eighteen months after the tion of treatment, it was evident that a substantial had been effected. Some slight softness only was arent at the position of the former growth, but there was no feeling of pulsation anywhere, save over an artery in the position of the occipital, and the ear, which was formerly so tumid, had returned to a moderate size. The hæmorrhagic tendency had not again manifested itself, and the patient's health and spirits were of the best.

Remarks.—The chief interest of this case lies in its close resemblance to the one treated by Mr. Storks and Sir William Fergusson, and narrated in the latter's System of Practical Surgery (p. 151), where much information respecting such cases will be found. Sir William Fergusson, however, trusted more to obliteration of the vessels in the growth by pins and ligatures, and Mr. Cardew to ligation *en masse.* In respect to all such cases it may be doubted if the treatment by pins or direct ligation could be safely applied without the preliminary tying of the chief nutrient artery, in reference to which question the following remarks of Sir William Fergusson are much to the point. "The practice above described was certainly attended with considerable hazard, both on account of the inflammation as well as the hæmorrhage, and it was not without misgivings that I adopted it. But the case seemed otherwise hopeless, and the previous obliteration of the common carotid led me to trust that such bleeding as might occur could be controlled. Without this preceding step it may be doubted if the result would have been equally successful; and I am therefore disposed to attribute the satisfactory issue to a combination of the two methods—viz., first, the obliteration of the main arterial current towards the disease, and then the destruction of the vessels in its substance." It is interesting, finally, to note the success of both these cases in the face of Billroth's direct condemnation of the treatment pursued (Surgical Pathology, vol. ii., p. 337), as interesting as it is to remember that the treatment which was written about so warningly by John Bell is that very one of extirpation most highly commended by Billroth.

Cheltenham.

THE BACILLUS OF SYPHILIS.[1]

BY DR. SIGMUND LUSTGARTEN,
FIRST ASSISTANT TO PROFESSOR KAPOSI IN THE DERMATOLOGICAL WARDS OF THE VIENNA GENERAL HOSPITAL.

TRANSLATED BY DR. J. N. BLOOM, B.A., M.D.

SINCE Hallier's time, a period of almost twenty-five years, the virus of. syphilis has been the subject of frequent communication and of almost constant discussion; but, nevertheless, the conviction is universal that none of these researches have even partially solved the question, because of their countless contradictions, inefficient methods, and errors that are easily recognised. And further, as my effort is not the continuation of any preceding one, I will not tax your time and patience by a review of the literature of the subject, but will at once detail my own observations, referring for the literature and development of the subject to a publication of mine shortly to appear.[2]

My researches with syphilitic products have led to the discovery of micro-organisms which until now were unknown, which are constant in their appearance, and which are thoroughly characteristic. They approach nearest in their morphological appearance and staining reaction to the bacilli of leprosy and tuberculosis, and, like these, are to be found in granulomata. By means of the method about to be given they appear as straight or curved, and sometimes irregularly bent rods, which are on an average from three and a half to four and a half micro-millimetres long, and from one-fourth to three-tenths thick. With a low power they appear uniformly smooth, presenting here and there a bulbous swelling at their extremities. With a homogeneous immersion lens (one-twentieth of an inch, Reichert) their surface appears irregularly undulatory, and slightly notched, yet in a manner such as to leave no doubt as to their rod nature. Within them we recognise, at equal distances from one another, oval, colourless, bright spores, from two to four in every bacillus. I never saw the bacilli lying free, but always enclosed in cells. These cells are from a trifle larger than, to double the size of, white blood-corpuscles. They are round, oval, or irregularly polygonal, and sometimes show a central or eccentric oval nucleus in the shape of a light spot. The bacilli are to be found in *them singly or in groups of from two to nine or more*, sometimes intertwined, or, again, in irregular confusion. The cells containing bacilli occur sparingly in the midst of the infiltration, more often on the borders of the same in the apparently normal tissue immediately adjacent. I have observed them in papules embedded between the prickle cells of the rete Malpighii, and also in the initial lesion in the lumen of a large lymphatic duct. It seems to me to be beyond doubt that they possess the power of active locomotion—migratory cells. To obtain these results I had to employ a new method. Starting with the idea that bleaching measures would be serviceable in microscopic work, as well as in the arts and trade, I succeeded, after numerous fruitless attempts, in finding what I sought in permanganate of potash and sulphurous acid. In brief the method is as follows. Sections, which have been hardened in alcohol, are coloured in a solution of gentian violet (Ehrlich-Weigert),[3] from twelve to twenty-four hours at the ordinary temperature, and then for two hours at a temperature of 104° F. The section, in order to be decolourised, is first washed in absolute alcohol for several minutes, and is then, by means of a glass or platinum needle, conveyed into a watch-glass containing about three cubic centimetres of a 1½ per cent. aqueous solution of permanganate of potash. In this it remains about ten seconds. As a result, a brown flocculent precipitate of the hyperoxide of manganese is formed in the fluid, and also covers the section. It is then placed in an aqueous solution of chemically pure sulphurous acid, in which it is deprived of the hyperoxide of manganese, either instantaneously or in a very short time, dependent upon the concentration of the acid; it now appears entirely rid of its colouring matter in some places, while in others it is still deeply coloured. It is next washed in distilled water, and is again placed in the solution of the permanganate of potash, in which, as in the succeeding repetitions, it remains three or four seconds, and from which it is again conveyed to the sulphurous acid. When it appears colourless, which as a rule occurs after this procedure has been gone through three or four times, it is dehydrated in alcohol, rendered transparent in clove oil, and mounted in Canada balsam. Xylol Canada balsam is best. This method of decolourisation, to which, besides those already mentioned, the bacilli of leprosy and tuberculosis do not yield, not only permits the micro-organisms of syphilis already described to be brought to view, but is a characteristic staining reaction of them. The bacilli of syphilis, leprosy, and tuberculosis are *not decolourised by my method. All other bacteria are.* The bacilli of syphilis, however, are differentiated from those of leprosy and tuberculosis in that the latter are not decolourised by nitric and hydrochloric acids, whereas the bacilli of syphilis are. My method failed in the examination of splenic fever, typhoid, equinia, endocarditis ulcerosa, croupous pneumonia, various secretions of wounds, the contents of acne and scabies pustules, and also in the examination of normal tissue. I wish also to mention that my attempts to prove the presence of these micro-organisms in two chancroids were futile.

---

[1] A paper read before the Royal and Imperial Society of Physicians of Vienna, on March 27th, 1885.

[2] Die Syphilis Bacillen, Wiener Medizinische Jahrbucher, first quarter, 1885; also as a brochure about to be printed by Braumueller, Wien.

By means of the method just given I have examined sixteen cases of syphilis, which I will simply enumerate without going into particulars. Sections of two initial lesions; a lymphatic gland; three papules and four products of the tertiary stage; and further, the secretions of three initial lesions, and of the same number of moist papules. The result was a positive one in every case. The number of bacilli found varied. In general they were not very numerous. As regards the number, the age of the infiltration, and perhaps also the length of time since infection, are of importance. Thus I found in every section of two initial lesions, and of a periosteal gumma in a new-born child, one or more groups of bacilli, and here and there quite large groups among them; whereas in other cases a series of sections had to be examined before the undoubted presence of bacilli could be confirmed. According to my experience, the proof of the presence of the bacillus in syphilitic products is of equal diagnostic importance to that of the tubercle bacillus in the sputum.

Inasmuch as I have found, as a constant factor in undoubted syphilitic products of various kinds, a special kind of bacillus which differentiates itself in form and staining reaction from all those known up to the present time, and which therefore is a specific bacillus, and as we believe ourselves justified as regards other infectious diseases in *assuming the constant occurrence of peculiar micro-organisms* to be the cause of the disease, I maintain, as regards syphilis, that it is very probable that the bacilli which I have discovered are the carriers of the syphilitic virus. In addition to this specially important result the above-mentioned researches present several other theoretically and practically important facts and deductions, which I will briefly mention. The occurrence of bacilli enclosed in lymphoid cells whose power of locomotion, according to my before-mentioned observation, is beyond dispute; further, the occurrence of bacilli in the apparently healthy tissue lying nearest the infiltration; and, finally, and most especially, their discovery in the initial lesion in a closed lymph-duct—support the theory that the poison of syphilis is conveyed from the place of infection, first by the lymphatic system, and later through it into the blood-vessels. The occurrence of bacilli in the rete Malpighii is of great theoretical interest, and accords with the clinical observation that in certain cases syphilitic infiltrations need only lose their covering of horny epidermis (moist papules) to be contagious.

As I have shown bacilli of the same nature as in primary and secondary products to exist in typical gummata, we must look upon the latter, as indeed do the greater number of syphilologists, as specific syphilitic affections. Only a few writers have evaded the difficulty, inasmuch as they consider gummata to be the result of a specific cachexia, and not of a syphilitic virus, basing their claim upon a number of negative inoculations, and pointing out that syphilitic patients in the tertiary stage, as a rule, produce healthy—i.e., non-syphilitic—children. Recall to mind how long Ricord and his followers maintained the non-infectiousness of the products of the secondary stage, where the circumstances were so much simpler, because of the much greater frequency, the situation, and the nature of the manifestations. Further, I cannot understand why because one has some local syphilitic deposit he should not have healthy generative cells, and as a result should not produce healthy children. In heredity we must not forget that there are affections of the generative glands which have, perhaps, no subjective or clinical symptoms, and yet are followed by the production of diseased generative cells, or, at least, of spermatic fluid containing the virus. I kn
from a personal communication of Armauer Hansen, an
have been in a position to convince myself of it, th
testes of leprosy sufferers contain numerous bacilli i
between the seminal ducts, whether symptoms of dise
the testicles exist during life or not. In the futur
question as to whether a given case is syphilis can on
affirmatively answered if the presence of the sp
bacillus can be demonstrated.

In conclusion, I venture to hope that by continuo
search, particularly in the cultivation and inoculation
bacillus which I have discovered, etiological relation bet
it and syphilis will be so decidedly proved that non
deny it, and that a means will thereby be attained fo
cessfully combating one of the saddest diseases o
human race. The experiences of the last few years i
successful attenuation of the virus of splenic feve
other infectious diseases warrant the hope that thi
pectation is not over-sanguine.

CLINICAL MEMORANDA OF TWO CA OF CHRONIC VAGINITIS.

WITH REMARKS.

BY J. BRAXTON HICKS, M.D. LOND., F.R.S.,

CASE 1. *Vagina throughout covered with granula*
freely bleeding; complete recovery.—A widow, of abou
years, applied to me in consequence of a constant
discharge from the vagina. To the finger it felt velve
granular, from os to vulva, bleeding on examination
passage of the speculum caused much distress, an
bleeding; and it revealed the fact that from one end
other the vagina looked as if covered by granulation
a healing wound. The bleeding being severe, it was
sary to swab the whole surface over with tincture of p

---

[3] One hundred parts of a concentrated aqueous solution of aniline with eleven parts of a concentrated alcoholic solution of gentian violet.

ride of iron diluted with three or four times its weight of water. This restrained the bleeding, but gave some pain. Astringent injections of tannin were used daily, and every third day the speculum was passed, and a sponge saturated with the dilute tincture of perchloride of iron left behind, and subsequently withdrawn. As this gave much distress, injections of the same solution were used alternately with tannin solution (two drachms to the half pint.) The vagina was very sensitive, and all manipulations were attended with distress. But at the end of a month she was free from the bleeding, and in a few weeks more the vagina had resumed its normal state.

CASE 2. *Severe chronic vaginitis, with constant and free secretion of pus for over a year; treatment by injections hitherto useless; cured.*—This case, though not raw and bleeding like that just described, was with this exception the most severe of any I have seen. Throughout the whole passage it was felt to be granular and velvety, and through the speculum the mucous membrane was observed pouring forth purulent secretion in large quantity. Her age was about thirty, married. The condition had come on gradually, and there was no information leading one to suspect it to have had its origin in gonorrhœa. She had been under treatment by injections for a year before I saw her. She was admitted under my care into Guy's Hospital, and the vagina treated by means of the speculum. Various applications were used in succession: nitrate of silver (twenty grains to the ounce) once; swabbing with the iron solution, as in the former case; plugging with cotton having powdered tannin diffused in it every day for some time—all of which gave gradual improvement. After a fortnight I applied a drachm of anhydrous sulphate of zinc to the upper half of the vagina, plugging it below with cotton well greased. This caused considerable pain and some exfoliation of the vagina; but when it had passed over, the vagina made a quick recovery, aided of course by continued though milder injections, till she left the hospital cured in about a month from admission.

It is not often that cases of like severity are seen; but many present themselves of long standing, with a granular state of the vagina and pus-like discharge, defying the former treatment. But these are obstinate only for the reason that they have not been thoroughly and perseveringly treated; either the syringing of the lotion has been inefficient, applied in vertical posture, or by a sponge only to the vulva, it having never properly reached the upper portion of the vagina. The mode of application is of more importance than the kind of drug employed. The material should be in contact with the diseased membrane for ten minutes at the very least, if possible for an hour, or, better still, for twelve hours; if used as an injection, the patient should be in the horizontal position. But it is best in all cases to commence treatment with a good swabbing of the upper half of the vagina with strong carbolic acid or iodised phenol through the speculum, which should be retained for five minutes, and then the superfluous portion removed by dry cotton. Care should be taken that a portion be not drawn down to the vulva; if it should be, pain will ensue; this, however, can be removed by washing the part with wet cotton. Care also must be taken lest the carbolic acid run down the speculum on to the thigh or drawers, for if it does, a blister will ensue, and much grumbling likewise. This carbolic application might be repeated in about six or seven days, whilst twice every day an astringent lotion can be employed as strong as can be borne without distress. Of these there are numerous kinds:—Chloralum solution (one ounce to the half pint), tannin (two drachms to the half pint), boroglyceride (one ounce to the half pint), the old sulphate of zinc and alum lotion, tannin and alum mixed, tannin with iodoform, bichloride of mercury (1 in 1000). Preceding the use of either of these, it is well to employ an antiseptic douche, in order to wash away the secretions which would impede the action of the astringents. But I prefer to apply every three or four days, through the speculum, a stronger astringent than can be employed by the syringe—such as the tincture of muriate of iron diluted three times, strong chloralum; or, as recommended by Dr. Oldham, the walls of the vagina can be kept apart by a plug of cotton. An excellent way of effecting this is by using pledgets of cotton with a string attached, diffusing through them dry powdered tannin and alum with a little iodoform, passing these through the speculum and leaving them behind, and removing them after twelve hours. This can be done every second or third day. But I think that although the healthy vagina tolerates anhydrous sulphate of zinc and the tincture of muriate of iron or the weaker solution, yet when it is abraded or spongy these agents are apt to cause exfoliation of too severe a kind. The ordinary sulphate of zinc or alum, however, it will readily bear. These and similar expedients will, if continued steadily, almost always cure the condition as far as the vagina is concerned; but inasmuch as the mucous membrane of the uterus is often involved, attention must be directed to this part, or the vaginitis will recur.

George-street, Hanover-square, W.

MALT AS FOOD.

BY J. MILNER FOTHERGILL, M.D.

MALT as food has a great future before it. In the process of malting (which is a rapid germination) a distinct change is brought about in the seed. By the action of the diastase the insoluble starch is converted into soluble dextrine, which goes sweet in the mouth, so near maltose is it. The malt-combings, which are too rich in albuminoids for the brewer's purposes, are useful when malt is looked at as a food. Malt contains dextrine (some diastase), soluble albuminoids and phosphates, and when ground is an admirable food, while it is not expensive. Its taste is pleasant. It can be made into a pudding with an egg and some milk, and as such is palatable. It can be made a constituent of a milk pudding with advantage. When the brewer mashes his malt with hot water the diastase remaining in the malt converts the dextrine into maltose, which the yeast (next added) breaks up into alcohol and carbonic acid gas. The best white malt is not heated to more than 190°, as the diastase is acted upon injuriously by a heat above that point. Maltose is a sugar which does not readily undergo the acetous fermentation, and, therefore, as Dr. Mitchell Bruce points out in his "Materia Medica and Therapeutics," "will not give rise to acidity and dyspepsia." This is a great matter, as the cane sugar the cook adds to stewed fruit and milk puddings readily undergoes the acetous fermentation in many stomachs. The lævulose sugar of fruit, like maltose, readily undergoes the alcoholic but not the acetous fermentation. Maltose being less powerfully sweet than cane sugar, a greater quantity is necessary to sweeten the pudding. If the raw starch, semolina, sago, or tapioca be first put in the dish by itself, and placed in the oven for an hour (taking care not to have it burnt by the oven being too hot), not only are the starch cells cracked, but a certain conversion of the starch into dextrine takes place. If to this be then added an equal quantity of ground malt and some hot milk poured on, and the dish be allowed to stand a few minutes before being put into the oven again, the diastase of the malt acts upon the farina and converts it into dextrine and maltose. Dextrine and maltose being soluble, the pudding is very thin. Such a pudding is admirably adapted for invalids and dyspeptics, as requiring scarcely any digestion in the body. For those with whom ordinary milk puddings produce acidity, such a pudding is specially suitable. Ground malt may be added to fresh milk, and forms an admirable food in cases of acute disease. Baked flour perhaps goes better with meat broths, to which it gives a high food value. (Well-baked flour requires but a touch of saliva to render it soluble, and, added to meat broths and gravy soups, renders them very nutritive.) Malt, being sweet, goes better with milk, or apple-water, or tamarind-water, or lemonade, and gives us a food which being all but independent of the digestive act, can be most usefully employed in the sick room. Beef-tea (which alone is scarcely a food) and milk-and-seltzerwater pall upon the palate of the sick person, who craves variety just as do healthy persons. The adoption of ground malt as a food will solve for us one or two knotty questions connected with feeding people when the digestive power is feeble. Drinks like lemonade, made with malt instead of cane-sugar, would not only not go sour in the mouth and stomach, but would contain some phosphates and soluble albuminoids, and so form admirable beverages in pyrexial states. The many malt extracts now in the market are well adapted for such end.

Park-street, W.

PATHOLOGICAL RELATIONS OF FIBROUS DISEASE.

BY CHARLES DAY, M.R.C.S., L.S.A.LOND.

IN asking permission to record in THE LANCET a case connected with a certain group of diseases presenting somewhat peculiar features, I am reminded of a passage in the preface of Mr. Abernethy's work on the "Constitutional Origin and Treatment of Local Diseases," where, supporting his opinion of the advantages resulting from the report of cases, he observes: "If diseases, like other objects which we mean to delineate, be placed in various points of view and illuminated at pleasure so as to show distinctly their various parts, one accurate representation would suffice; but we see them obscurely, and as knowledge increases it seems like light shining from different places to illuminate the various parts of our examination." Thus I think it may be allowed that although the mere account of any case of morbid growth may not be susceptible of practical deductions available in the treatment of such disease, yet it may bring to our knowledge some accompanying phenomena hitherto unobserved, some special characteristic attending the case under observation, or the absence of the special physiological effects usually observed as resulting from the interruption to or cessation of the functions of some particular organ; and I think in the case I have to narrate there will be found points of sufficient interest to merit attention.

A lady, aged forty-five, married, no family, no miscarriage, menstruation having ceased without constitutional disturbance, of good height, fine figure, excellent physique and health, the only interruption being occasional attacks of biliousness attended with "sick headache," having had some fatigue and anxiety from attendance on a sick relative during the month of January, 1882, necessitating her getting up perhaps more than once in the night to see to the invalid in the adjoining room, was attacked with catarrh. As this subsided she complained of pain in the lumbar region and shoulders, which was regarded as rheumatism resulting from the cold. But in March inconvenience was experienced from a frequent desire to pass water, with difficulty in micturition, which increasing, an examination was made on April 2nd. There was no fulness in the hypogastrium indicative of any accumulation of urine, neither was there any tenderness. On passing the catheter not more than half a pint of urine flowed out; but although the quantity was small it afforded some relief. It was of a natural colour, sp. gr. 1019, and healthy to ordinary tests; no sediment, merely mucous cloud. After a short use of the catheter, the quantity removed each time being very small, the irritability of the neck of the bladder gradually subsided, but returned in a fortnight, causing painful efforts of expulsion, with the result of passing only a few drops at a time. This condition suggested the necessity of a more thorough examination, for although there was no sign of uterine trouble save the pain in the back, now of diminished force, the rheumatic character of which appeared to be confirmed by its attacking the lower extremities, the knees, ankles, and feet becoming very painful and swollen, the joint of the great toe presenting the usual appearance of gout, the patient at the same time being exceedingly apprehensive of and sensitive to anything touching the foot, yet treatment affording no relief, and nothing to be detected amiss with the bladder, it was evident the mischief was deeper seated. On passing the finger into the vagina it encountered an obstruction which felt like the os uteri, patulous, thickened, and corrugated, the first impression being that it was a case of prolapsus, but proved to be a fibrous growth springing from the sides of and encircling the ostium vagina. Passing the finger through the centre of this growth, the upper part of the vagina felt as though roofed in with a firm, smooth body—the uterus retroverted,—the walls of which were infiltrated with fibrous deposit, the whole being firmly adherent to the brim of the pelvis, the result no doubt of perimetritis. In the left labium was a fibroid perfectly round and smooth the size of a large gall-nut. In the left labium was a similar growth of smaller size, and on examining the rectum patches of induration could be felt. From the commencement to the end of the case there was not the slightest tendency to hæmorrhage, neither was there any discharge beyond a slight moisture, having no unpleasant smell save a faint odour somewhat resembling blood halitus. The progress of the case became very rapid, the growth in the vagina increasing until the central orifice was not larger than a No. 12 bougie. For the first two months the appetite was fairly good, but gradually became more and more impaired; then came on nausea, pain after food, and at last rejection of food by vomiting, unaccompanied with coffee ground sediment, merely the food returned. The urine—dating from the time when the catheter was first used, April 2nd, when scarcely half a pint could be withdrawn — became less and less in quantity until none could be withdrawn by that instrument; and from June 2nd to June 16th, when the patient expired, the secretion entirely ceased. During this time no inconvenience or any desire to void urine was experienced; neither was there any accompanying ascites, anasarca, or delirium, no evidence of toxic action from retained urea, unless the sickness and rejection of food could be referred to that cause, and not to malignant disease. The mind remained undimmed until the last moment arrived. Only for a short time in May did she complain of being disturbed by dreams, generally of an absurd tendency. No pain was present to add to the suffering of the patient and the distress of friends. The restless tossing to and fro, the very weariness of weakness as strength went out with the ebb tide of life is painful enough to experience or to watch. The emaciation became extreme and the skin assumed such a remarkable whiteness that it might well be taken to represent the reflection of "pallida mors."

There are several interesting features in this case, which, I think, may be pointed to as deserving consideration. Thus, the urine, which from an early period of the illness was scanty, diminished in two months from the small quantity of half a pint secreted in twenty-four hours to *nil*, and for the long period of fourteen days not a drop was secreted, or if secreted did not find its way to the bladder. If formed without passing from the body, one would naturally look for some corresponding systemic disturbance, some fluid infiltration into cellular tissue or cavity, some disturbed mental functions; but no, we observed none of these things. The stomach alone exhibited disturbed action, which might have resulted from that cause, but which I think there is far greater reason to believe arose from the same organic change which had invaded so many other parts of the body. Then the bowels became equally dormant without any abdominal fulness, so that ingesta being refused, feeding per rectum of no avail, and the natural outlets for refuse material being closed, one might almost describe the wasting of the body as a process of natural cremation through the lungs. The general state of fibrosis is also remarkable. The vulva, vagina, uterus, rectum, and doubtless the kidneys and stomach, were all impregnated with the same morbid material. The suddenness of its development in an apparently healthy person, its rapid progress, the absence of pain, hæmorrhage or any discharge, the want of a probable cause of its inception, and other circumstances previously referred to, all tend to give additional interest to the examination of the subject, and make us pause, as we too freqently are obliged to do, when endeavouring to trace the why and the wherefore, the *fons et origo*, of those many mysterious and manifold changes which constitute the deviation from that happy state called health, the lot of so few of us, to that other state designated disease.

In formulating a history for the case one is somewhat at a loss. What shall we say? Was it a constitutional cachectic diathesis, such as one might affix to cancer attributable to heredity? or caused by local irritation acting through nervous conduction on an anxious and depressed condition of the mind, inducing by some unknown agency such a change in the blood and eliminating organs as to result in the formation and general deposit of this special morbid material? The pathological position of fibrous disease I think is at the present unsatisfactory, and remains one of interest and doubt. Whether it is a disease *sui generis* of independent origin, unassociated with any disease, acting, as one may say, *loco parentis*, or whether it is essentially cancerous in its nature, and therefore connected with heredity, as held by Dupuytren, Ashwell, and Hodgkin (an opinion which may yet find upholders), is a wide subject for discussion and beyond the scope of this communication. But a case in which scirrhus of the breast existed with fibroid in the vagina, similar to one reported in a recent number of THE LANCET, leads not illogically to the view that, if not identical, there is much to favour the opinion that diseases so associated may result from a similar onstitutional idiosyncrasy capable of developing the one r the other. Inquiring into the family history of the atient, I could not hear of any member who had suffered rom cancer in any form, but there had been *gout*, an ttack of which manifested *itself* during the progress of his case.

Since reading Mr. Hutchinson's admirable Bowman Lectures, in which he traces a very intimate connexion between gout and various diseased conditions of the eyes, I have been impressed with the thought whether a similar relation may not be found to exist between that disease and other maladies, such as the one in point and *others of a more* malignant character. *Additional force* has been lent to the thought by the following circumstance. A family with a long history of gout has in the last two generations suffered but little inconvenience from it. The grandfather of the present generation was the last who experienced any violent attack. He was a "martyr to it," and crippled by it. He had four children, two sons and two daughters. Of these one of the sons only had two sharp attacks in middle life, remaining free up to the time of his death, which occurred at the age of seventy from cancer of the pylorus. Not one of his six children had any positive attack of this complaint (gout), *although two of the sons* had *enlargement of the great toe*-joint, but one daughter died of cancer of the breast, two sons of cancer of the bowels, and one son of cancerous ulceration of the leg. Cancer was unknown in this family when gout was in the *ascendant*. I *can* relate another case of a lady having gouty ancestry who became the subject of scrofulous ulceration of the glands of the neck. Some time after these healed a fibrous tumour formed in the *uterus attaining* a large size, unattended with pain or hæmorrhage, the health remaining unaffected. Sir James Paget also in his Bradshawe Lecture, "On Some Rare and New Diseases," like Mr. Hutchinson, *tracking certain of them, more perhaps by history* than pathology, discovers gout to be the source whence they spring, suggesting that as the typical form becomes less common, others hitherto unknown, or but little recognised, assume a prominence and attract *attention* by their increasing number, and though presenting at the first glance scarcely any feature by which their relationship would be suspected, yet, as he observes, "types vary in diseases as in species," and "the certainty and probable extent of this variation must seem the greater if we consider the mingling of diathesis in transmission from and through both parents." Thus he says, "In phlebitis we very *often trace* a variation from the customary type or standard of the very old and heritable disease—gout; in short, all the evidence of being one of the many forms of what is called incomplete gout." Osteitis deformans, rickets, and mollities ossium appear to have some relation to gout, "for some of the cases have known inheritance of gout," and are sometimes seen in "typically gouty persons."

It must be allowed that in searching after an "unknown quantity" a certain amount of guessing is permissible, and I think, with Sir J. Paget, "that it is a legitimate use of the imagination which may happily discern a way towards the truth." Hence, when we find fibroids and cancer associated or separated, yet blastemal formations developed in individuals of a typically gouty descent, it can scarcely be called "using the imagination to the furthest bounds of propriety" to suggest that they both owe their existence to the same dyscrasia. As one swallow does not make a summer, so deductions made from one or two cases may perhaps be regarded as only hypothetical, yet they may serve as a basis on which co-operation may establish a substantial structure of facts confirmatory of the view here suggested.

St. Mark's-square, West Hackney, E.

THE BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.—On the 27th ult. a meeting in furtherance of the interests of this hospital was held in the Jerusalem Chamber, Westminster. The chair was taken by Sir A. H. Layard, and amongst those present were Sir Edmund Lechmere, Bart., M.P., Hobart Pasha, Sir Richard Temple, and Mr. Mocatta. The hospital was founded in 1882 by the English branch of the Order of St. John, and is chiefly intended to provide proper treatment for the peculiar diseases of the eye prevalent amongst the population. At present the hospital contains only four beds, and is maintained at an annual cost of £300, but double the amount is needed to carry on the work effectually.

CHARING-CROSS HOSPITAL.

CASE OF LATE CONGENITAL SYPHILIS OF THE THROAT; TREATMENT WITH MERCURY AND RECTAL ALIMENTATION; CURE; REMARKS.

(Under the care of Dr. BRUCE.)

THE diagnosis of the later manifestations of congenital syphilis is sometimes extremely difficult, especially when, as in the case which we publish, there are few, if any, *signs* in the patient *himself of previous* disease. In the absence *of* personal and family history *in such* cases it is sometimes necessary to wait until the effect of treatment has been tried. Although congenital syphilis at the age of this patient is not often fatal, still from the situation of the local lesion it may become so, and the treatment by nutritive enemata which Dr. Bruce adopted had without doubt very great influence in producing the cure of the case.

W. D——, *aged* thirteen, from Kent, was admitted into Charing-cross Hospital on Sept. 2nd, 1884, *suffering* from severe ulceration of the throat.

History.—He stated that his illness commenced about a month ago with inflammation of the lungs, followed within a week by the sore-throat, which has persisted ever since. From the first there was pain on swallowing and discharge from the mouth, and he immediately began to lose flesh. Previous to this illness the boy had been fairly healthy, but not robust. It was ascertained that as a baby (? aged two years) he suffered from rash and snuffles, and was treated at King's College Hospital. He *has recently been living in an isolated* house, in a healthy district, and the drains have been in good condition. He is the second of nine children; the eldest is alive and well, but all the others snuffled as babies, and several are *dead*. *His father* is alive and well. His mother miscarried five times.

Condition on admission.—The patient is a wasted, fair-complexioned boy, confined to bed. He lies with the mouth *open, in obvious distress in the throat*, and speaks with a very indistinct nasal voice. The skin is of an earthy tint and very dry, without rash or œdema. The uvula and posterior border of the soft palate have entirely disappeared, leaving an ulcerated *margin*; *anterior to this the* palate is red and shiny. The posterior wall of the pharynx is entirely occupied by a foul greyish-yellow slough, which extends upwards and downwards as far *as* the eye can reach. There is no swelling of the glands of the neck. The patient takes food indifferently, owing to dysphagia; part returns through the nose, and part is rejected by vomiting. The liver and spleen are not enlarged; bowels confined. A *hacking* cough ends in expectoration of mucus and sloughs detached from the pharynx, which contain no tubercle bacilli. The physical signs connected with the lungs, heart, and abdomen are normal. Pulse 74, regular, weak; urine scanty, sp. gr. 1033, without sugar or albumen. Sleep good.

Diagnosis.—Syphilitic ulceration of the throat, congenital.

Treatment.—Mercurial ointment (half strength), a portion as large as a hazel nut to be rubbed into the adductor region of the thigh daily. Pharynx to be rubbed with solution of nitrate of silver, twenty grains to the ounce. To be fed by nutrient enemata of beef-tea, yelk of egg, and brandy, four times a day, whilst allowed to take what food he cares to attempt by the mouth.

Progress of the case.—Sept. 12th: Very little but still decided improvement; rectum becoming irritable. Two minims of tincture of opium added to each enema. Little change in throat. Strength of silver solution increased to forty grains to the ounce. A little brandy taken by the mouth.

16th.—Marked improvement; the patient looks more lively and the throat is less foul, the soft palate looking more healthy, its posterior margin more raw, and the pharynx less thickly covered with sloughs. The enemata are better retained; a little food, both solid and fluid, taken by the mouth. Urine very scanty and high-coloured.

19th.—Strength increases; but little change in throat since the 16th. Most of the enemata retained; very little food can be swallowed. Spirits improving; voice still thick and nasal. Throat to be swabbed out twice a day with silver solution, sixty grains to the ounce.

24th.—Marked improvement. He sits up for an hour, and is more active and cheerful. No dysphagia; no regurgitation of food; enemata all retained. Back of pharynx presents only a thin slough; posterior part of soft palate merely reddened.

26th.—Moves about the ward. Throat greatly improved, the red base being seen through the grey surface of the pharynx, and the edge of the soft palate looking healthy. Can take most of his food by the mouth, but has still four nutrient enemata daily. Strength of silver solution reduced. Gargle of chlorate of potash ordered. Urine more abundant.

30th.—The slough has entirely disappeared from the pharynx. Strength increased, but three pounds weight said to have been lost within three days.

Oct. 3rd.—Throat now clear. Further loss of two pounds, but strength increased. Slight salivation. Mercurial reduced to one half.

7th.—Weight has increased two pounds. Salivation continued. Mercurial inunction stopped.

10th.—Nutrient enemata stopped. Meat diet by the mouth.

14th.—Steady increase in body weight. Still salivation.

17th.—To take syrup of iodide of iron.

21st.—Has gained two pounds weight in three days. Great improvement in general appearance. Adhesions forming in pharynx, with small points of ulceration.

Nov. 19th.—Discharged cured.

Clinical remarks by Dr. BRUCE.—This case was of considerable interest from its nature, and from a certain degree of difficulty attending its diagnosis; chiefly, however, in connexion with the details of treatment. Active congenital syphilis at the age of thirteen is not so common but that it deserves record, and its diagnosis as a matter of fact may be very far from easy at first. In the present instance the previous personal history and the family history of infantile snuffles were not obtained for several days after admission, and during this time the true nature of the illness was the subject of some discussion. The question of tubercular ulceration was raised, but the absence of swelling of the neck alone went far to dispose of the suggestion. The best immediate evidence of the correctness of the diagnosis of late congenital syphilis was the result of the severe treatment to which the patient was subjected. He was at once put upon mercury. But here a great difficulty arose; the patient could not swallow. Dr. Bruce urged upon the students the absolute necessity of ensuring an abundant supply of nourishment to the tissues whilst a powerful alterative like mercury is being allowed to act upon them. It was contrary to all sound clinical rules to administer mercury to a starving child, and a patient unable to swallow was virtually starving; but just as certainly the patient would shortly die of syphilis. Feeding *per oram* was therefore given up definitely, and regular nutrient enemata ordered instead, whilst the patient was permitted to attempt to eat occasionally small portions of nutritious food. The method proved successful. A stronger solution of nitrate of silver might have been used from the first for swabbing out the throat, but the shock attending free cauterisation of the whole pharynx might have been too great in the prostrate condition of the patient. As occasionally happens, the rectum, which was irritable at first, came to retain the nutrient enemata very well. There was free salivation for a time, although the mercury was reduced, and soon omitted when the mouth became tender. Another curious fact was that the boy continued to lose weight, whilst his general appearance and strength and the local disease were all steadily improving.

DUNDEE ROYAL INFIRMARY.

ABDOMINAL SANGUINEOUS CYST; ASPIRATION; RECOVERY; REMARKS.

(Under the care of Dr. SINCLAIR.)

J. G——, aged fifty-one, flaxdresser, was admitted on May 14th, 1883, with the following history. About two months previously he observed a smooth round swelling just below the umbilicus, which rapidly increased in size; it caused no discomfort except that arising from its rapidly increasing bulk.

On admission, a rounded swelling, quite smooth to the touch, could be made out in the umbilical region of the abdomen, but extending slightly into the other regions. It was of firm consistence, and appeared to be adherent to the anterior wall of the abdomen (the umbilicus not being movable over it). No fluctuation or impulse could be elicited. There was no bruit on auscultation. The tumour occupied the umbilical part of the epigastric, hypochondriac, and right lumbar regions, and a very small portion of the hypogastric region. It was clearly separable from the hepatic dulness by a narrow resonant line, and it did not move with respiration. The hepatic and splenic dulness were of normal extent; no abnormal signs were discovered in the lungs; the cardiac dulness was normal, but the sounds were weak; tongue slightly furred but moist; appetite good; bowels constipated; temperature 99°; pulse 70, weak; respiration 28; urine pale, slightly acid, sp. gr. 1018, no albumen.

17th.—Hypodermic needle was inserted into tumour, and a syringeful of dark sherry-coloured fluid was readily withdrawn. The fluid contained nearly 50 per cent. of albumen, abundant red blood-corpuscles, and some amorphous masses. No echinococci or hooklets. Sp. gr. 1020.

21st.—The tumour was aspirated in its centre, and sixty ounces of fluid were withdrawn, of the same character as that removed by the hypodermic syringe.

22nd.—The patient complained of sickness yesterday after the operation. No trace of tumour.

June 2nd.—Patient got up.

6th.—He was dismissed in good general health, the tumour having entirely disappeared.

Remarks by Dr. SINCLAIR.—I can find no description of a similar cyst in Bright's classical memoirs. One, in some respects similar, is described by Bauer in Ziemssen's Cyclopædia.[1] It terminated fatally after two tappings. In THE LANCET of May 5th, 1883, Dr. Bristowe described two cases of abdominal cysts which resembled the one just described in the rapidity of growth and sanguineous contents. The first he concluded to be probably either a simple cyst of the spleen or a distended kidney, more probably the latter. The second had a much larger history, and was found on post-mortem examination to have been a sanguineous cyst resulting from a round-celled sarcoma. Dr. Clifford Allbutt has described a case[2] presenting some points of resemblance to mine as regards its contents; but it had a rather higher situation, required three aspirations, re-formed subsequently, and then disappeared after an attack of diarrhœa and colic. Dr. Oliver's case,[3] which occurred in a female, yielded 148 ounces of blood-red fluid on the first, and 84 ounces of similar fluid on the second, tapping, made a much slower recovery than mine, and was considered by him to be probably a hæmatocele of ovarian origin. The case described by my friend, Dr. Reid, and which was watched with great interest by us all, was clearly, I think, unconnected with any of the solid viscera of the abdomen. That it was not hydatid was evidenced by the absence of hooklets on careful microscopical examination. I can see no ground for considering its origin malignant. The impression is that it was a cyst of peritoneal origin, possibly owing to a traumatic cause, as the patient is a man of intemperate habits. I saw the man some time ago, a year after dismissal, and found him in good health, and quite capable of performing his usual work; but I thought I discovered some traces of reaccumulation. As cases of this kind are of great interest and rarity, I shall keep a watch on the patient, and report his further history should the disease return.

DOUBLE THORACIC ANEURYSM; DEATH; AUTOPSY.

(Under the care of Dr. SINCLAIR.)

For the following notes we are indebted to Mr. J. Mackie Whyte, M.A., M.B., house-surgeon.

J. W——, aged forty-nine, a tall well-built man, employed as a labourer in a jute works, was admitted on Feb. 14th, 1884, as an urgent case. His history was that he had been subject to pain in the chest since the middle of December, 1883, when he fell downstairs while drunk, and received a scalp wound, but no other external injury. The wound healed, but the pain in the chest became worse, catching his breath. For the past fortnight his voice had been hoarse, and he had had a troublesome cough, with inability to expectorate the mucus, which caused a disagreeable rattling noise. Had been in the army; while there he had acquired syphilis; otherwise previous health had been good.

---

[1] Vol. viii., pp. 338–39.

[2] THE LANCET, July 7th, 1883.

[3] Ibid., Oct. 11th, 1884.

On admission, he was in a state of great dyspnœa; he spoke in a hoarse whisper; cough of a ringing character; throat dry; no difficulty in swallowing; pupils equal; radial pulses equal, 54 per minute, regular; pain in region of heart apex on any exertion; a "gripping" pain, constant, in interscapular region; general præcordial heaving, and epigastric pulsation; apex-beat in fifth space, nipple line; systolic murmur in mitral and aortic areas, loudest in mitral; second sound accentuated, with a distinct pump-valve character, best marked in aortic area; dulness in upper part of thorax extending from one inch to right of manubrium across sternum for five inches. This dulness was continuous with the cardiac dulness. There was also dulness in the left interscapular region, opposite the spine of the scapula and a little below. The second sound was distinctly heard accentuated over this area. Physical signs of lungs normal, except for occasional bronchitic wheeze. Examination of larynx showed paralysis of left vocal cord. Urine normal. Great improvement followed the treatment, which consisted of rest in bed and administration of bromide and iodide of potassium internally. On May 19th the patient was sent to the Dundee Convalescent Home, but was refused admittance, as he had got drunk on the way.

He presented himself again at the infirmary on Oct. 29th, as bad as ever. Had been employed chiefly in carrying bales of jute; always felt a "gripping" pain in the chest when lifting. Physical signs much the same as when in the infirmary before. Left radial pulse smaller than right, 66 per minute. Improvement was slow, and relapses of dyspnœa occurred. Towards the end of November breathing was very noisy.

On Dec. 10th, about 10.15 A.M., the patient, who had been sleeping quietly, was seized with a paroxysm of dyspnœa. There was laryngeal stridor, like cock-crowing; the face became blue, and he sprang out of bed, saying he was dying. In about five minutes he expired. His face became pale after death.

Autopsy.—Right pleura adherent in whole extent; some tough adhesions also in left, especially near the upper part. Thoracic contents removed in mass with some difficulty, on account of close adhesions to the vertebræ. There had been no escape of blood from the vessels. Heart empty of blood; both auricles dilated, walls very thin; left ventricle considerably hypertrophied. Aortic valve incompetent; no vegetations but dilatation, circumference being three inches as measured when laid open. Mitral valve somewhat dilated. Ascending part of aorta showed fusiform dilatation, circumference four inches. Wall atheromatous, with calcareous deposits. The dilatation extended as far as the origin of the left common carotid; the vessels arising from the arch were not themselves involved. Thus the transverse portion towards its termination was of normal calibre, but at the bend it suddenly dilated into an aneurysm larger than a cricket-ball. This consisted of two parts, separated by a constriction; the anterior had the same lining as the aorta, with which it was obviously continuous, the posterior had a wall which was dark in colour and rough, and was largely filled by a laminated organised clot. The pressure of this part had caused deep erosion of the bodies of the third, fourth, and fifth dorsal vertebræ, in front and on the left. The left vagus was traced over the transverse part of the arch and its branch, the left recurrent laryngeal was followed round part of the aneurysm, where it was thickened and irregular, and up alongside the trachea. Neither trachea nor œsophagus showed any effects of pressure; the latter was close to the aneurysm. Lungs much congested; also the abdominal viscera. Fibrous adhesions from old peri-hepatitis all over the liver.

Remarks by Dr. **SINCLAIR**.—The history of this case clearly suggested aortic aneurysm; the symptoms on admission pointed most distinctly in the same direction; and the physical signs left no doubt that we had before us a case of aneurysm of the arch pressing on the left recurrent laryngeal nerve. In every respect, then, the record was singularly complete and satisfactory up till the moment of the patient's death, which occurred quite suddenly. The autopsy showed that it was not due to rupture of the sac, as might have been anticipated. In the absence of any other quite satisfactory explanation, I suppose paralysis of the heart may be suggested as the most likely cause. The case is interesting also from the fact that there were two distinct aneurysms, separated by a short interval of aorta of normal calibre. This circumstance alone seems to me to be of sufficient interest to justify its being placed on record.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on Cholera.

THE adjourned discussion on cholera was held, and the debate concluded, on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair.

Dr. **HENEAGE GIBBES** said that he fully agreed with everything that Dr. Klein had said. In acute cases of cholera, instead of a pure cultivation of comma bacilli in the lower part of the ileum, comma bacilli were to be found few and far between. Cultivations of the small straight bacilli in a large number of test tubes proved that these bacilli were not young comma bacilli, but belonged to a distinct species, for they grew in a totally different manner, did not liquefy the gelatine, grew on the surface chiefly, and were not motile. That the comma bacilli were not discovered in the tissues was certainly not due to defective staining. He had used every possible staining fluid and combination of fluids, but had found no comma bacilli, in the intestinal walls. A case of infantile diarrhœa showed a more pronounced morbid change in the intestines than exists in cholera, and so the intestinal lesion could not account for the collapse of cholera. In one case in Lieberkühn's follicles many putrefactive bacilli were present, and this specimen was shown to the Society.

Sir **GUYER HUNTER** said that, as he understood, Koch had shown that the comma bacillus stood in the relation of cause and effect to cholera. He did not believe that cholera was dependent on the action of a germ. He referred to the characters of the last outbreak of cholera in Egypt and in France as proving his contention. The report on Egyptian cholera presented to Her Majesty's Government also maintained the same views. He considered that cholera had been proved to be non-contagious. A surgeon, writing in the *Practitioner* of July, 1875, advised the injection of chloral hydrate in doses of 10 grains in 100 minims; this treatment in his hands had been so disastrous that he was compelled to stop it. He did not agree that opiates increased the danger from collapse; any premonitory diarrhœa should be treated by opium and stimulants. He believed cholera to be due to a series or combination of conditions. If the germ is killed by decomposition, then cholera ought not to exist in localities where filth and garbage abound. Strict hygiene was the only way to prevent the occurrence of cholera. Any form of ill-health predisposed to cholera.

Dr. **PYE SMITH** spoke of the choleraic discharge, and agreed with Cohnheim that this was not of inflammatory origin. In cases of cholera sicca large quantities of detached epithelium were present in the intestines, but this was probably the result of post-mortem change. Moreau obtained a "paralytic secretion" by section of the mesenteric nerves, and the large quantity of effusion thus obtained coincided in many respects with the choleraic discharge. The nervous influence was conveyed, not through the splanchnics or vagus, but by way of the smaller mesenteric ganglia derived from the solar plexus; and excision of these ganglia led to the production of a large intestinal effusion. He was in accord with the generalisation made by Gaskell, to the effect that the exciting influences were conducted by means of grey nerve fibres, whilst inhibitory influences passed along the medullated nerve fibres.

Mr. **MACNAMARA** said that no epidemic was known to have arisen outside the confines of British India. The statements made by Klein with regard to infection were in absolute variance with the conclusions of all previous workers. It was remarkable that the comma bacillus should correspond to the characters of the contagium as described by Parkes—viz., that it was destroyed by acids, that its life in water was very brief, and that the conditions under which the water was placed must be of a certain kind. He referred to the case in which choleraic discharge polluted some water of which nineteen individuals drank, and within thirty-six hours five of these persons were dead of Asiatic cholera. He quoted many circumstances and incidents tending to prove that cholera was a contagious disease. From his observations made on individuals dead of cholera, he could not agree with the views expressed by the President on the existence of spasm of the pulmonary arterioles, for he had not found distension of the right side of the heart. He was not successful in the treatment of cholera by castor oil; he had seen the best results by the use of opiates and astringents.

Dr. John Murray thought that the habitat of the poison of cholera was the mucous membrane of the intestines: it first caused paralysis of the sympathetic, which prevented the excretion of effete material. The left ventricle was sometimes occupied by a coagulum, which was black at first, but tended to become decolourised. A feeble fluttering pulse was the sign of the formation of a clot in the heart. In his experience laxatives were most dangerous, and in this he was corroborated by the experience of observers in all parts of India. Any remedy which promoted the secretion of the bile and gastric juice was of value in the early stage of cholera. Transfusion of hot saline solutions caused the spasm of the pulmonary arterioles to pass away.

Dr. Heron reverted to the question of the bacteriology of cholera. From the beginning of the growth of the various comma bacilli, it was possible to distinguish Koch's bacillus from all the others. All the comma bacilli could be distinguished from one another. In cholera nostras the comma bacillus of Finkler would be found, and not the bacillus of Koch. He thought that cases of cholera might be distinguished from cases of cholera nostras by a cultivation of the comma bacillus; the mode of growth was so different. He said that Koch and Klein agreed that there was a comma bacillus peculiar to cholera, which was to be found nowhere else. The comma bacillus of Lewis was different from that of Koch. He had examined eight cases of tubercular diarrhœa without discovering the comma bacillus of Koch, and so could not agree with Klein's statement on this point. Koch and his staff of assistants held themselves in readiness to go to any part of Germany in order to determine by bacteriological research whether a case submitted to them was one of Asiatic cholera or not. We were indebted to Koch for this possibility of diagnosing true cholera, as we were for so many other discoveries in medical science.

Dr. Thin said that many people certainly believed that the comma bacillus of Koch could be found in other diseases and conditions besides cholera; he thought that Dr. Klein, or those who reported him, were responsible for this impression. He narrated circumstances which seemed to show that hygienic conditions, and kinds of food, such as lettuces manured with human excreta, did exercise an influence in the production of cholera.

Dr. J. Johnston had had much experience of cholera at Shanghai. Cholera prevailed when the fruit season began. Cholera was predisposed to, if not caused by errors in diet, carelessness in the use of purgatives, and other forms of indiscretion. Drinking water was certainly active in the causation of cholera. Evacuant treatment in his hands was decidedly harmful.

Mr. Sedgwick said that at the time he wrote his work on the Urinary Secretion in Cholera and Diarrhœa he was not aware that urea was a binamide of carbonic acid; knowing this he had less difficulty in understanding how the preformation of carbonic acid in the tissues and blood should continue and the preformation of binamide of urea should cease through the defective oxidation of the blood. M. Doyère had investigated the chemistry of respiration in cholera. In normal respiration there were 44 vols. of CO_2 discharged in every 1000 vols. of expired air to every 165 vols. of oxygen taken up. The relative diminution in the amount of carbonic acid in the expired air in cholera was accompanied by an increase in the proportion of the oxygen. In collapse about three-fifths of the normal quantity of CO_2 were discharged, and the oxygen absorbed was largely in excess of the carbonic acid eliminated. In cholera the mammary secretion and all other secretions having to do with the generative organs were not interfered with. Encysted dropsy of the ovaries suffered little or no diminution in amount. Anasarca might disappear completely, as Dr. Barlow had shown, in cases which recovered. Menstruation was not delayed or checked in cholera unless the period were about to commence. The liquor amnii and urinary secretion of the fœtus were not stopped. He did not agree with the view expressed by Mr. Simon, that cholera always proved fatal to the fœtus, and quoted some statistics of a French author in this regard.

Dr. Maclagan believed that the poison of cholera was a micro-organism, for nothing but a living thing could reproduce itself. It was a peculiarity of parasites that each had its own nidus. Cholera had its relationship with the acute specific fevers. The nidus in cholera was the epithelium of the internal viscera, and especially of the small intestine. He did not agree that the shedding of epithelium was a normal post-mortem change. The collapse of cholera might be likened unto the rigor of onset of the specific fevers.

Mr. Scriven could not understand how the viscidity of the blood in cholera could not be due to a loss of water, for the blood had unlimited power of appropriating fluid from all the tissues. He could not agree with the views of the President in this respect. He dwelt at some length on the treatment of the various stages of cholera.

Dr. Lowndes said that diffusible nutritive fluids, like Liebig's raw soup, in small doses every half-hour, were most valuable in the treatment of cholera.

Dr. Johnson, in reply, maintained that the distension of the right side of the heart was a fact testified to by Dr. Edmund Parkes before his own observations and experiments had been made. Dr. Sutton, in the fourth volume of the London Hospital Reports, confirmed the same observations. The right side of the heart was distended and the left nearly empty in cases of cholera. He said that chloral hydrate did not abolish arterial spasm. He contended that spasm of the pulmonary arterioles explained the greater number of the phenomena of collapse, and still maintained the accuracy of his views as to the evacuant treatment in the early stages of cholera. He fully recognised the existence of cholera so severe that no treatment could avail.

CLINICAL SOCIETY OF LONDON.

Treatment of Spina Bifida.—Choreiform Movements in Infantile Spasmodic Paralysis.—Carcinoma and Calculus of the Bladder.—Pistol-shot Wounds.

An ordinary meeting of this Society was held on the 27th ult., Mr. Thomas Bryant, F.R.C.S., President, in the chair.

Mr. Mayo Robson (Leeds) read a paper on a Series of Cases of Spina Bifida treated by Plastic Operation. He described four cases on which he had operated:—Case 1. A. S——, aged six days, was the subject of a spina bifida the size of an orange; operated on Oct. 26th, 1882. The child lived and thrived for a year, when it died after a day's illness from teething convulsions. The site of the tumour presented only a linear scar. The interposed periosteum had not formed new bone. (The excised sac was shown to the Society.) Case 2. Mary A——, aged eighteen days, a puny, ill-developed child, with a large spina bifida in the lumbar region; the sac was thin and translucent quite to the margin of the tumour, and the skin around inflamed. It was all excised except two narrow portions, which were sufficient to form meningeal flaps, these being covered in by skin flaps obtained by separation and sliding from the lumbar regions. The wound healed by first intention, but the child died from a continuation of the marasmus present before operation. At the autopsy the whole lumbar spine and part of the sacrum were bifid. There was no meningitis. (Specimen was shown to the Society.) Case 3. L. J——, aged sixteen, the subject of spina bifida in the lumbar region, the size of a fœtal head, was admitted to the infirmary to have tenotomy performed for talipes. The sac of the spina bifida began to inflame the day after admission, before any operation had been done, and produced high fever and severe head symptoms, threatening life. It was aspirated eight times between November 13th and December 9th, the last three aspirations yielding pus. She was rapidly losing ground and apparently sinking, so on December 11th Mr. Robson excised the sac after reflecting the skin by crucial incision; the cavity was drained for a few days. The head symptoms were at once relieved, and she recovered rapidly, being discharged cured twenty-four days after operation, with the wound quite healed, and only a scar where the tumour had been. (Patient shown to the Society.) Case 4. D. C——, aged seven, had a spina bifida in the lumbar region, seven inches and a half in circumference; sac thin and inflamed at fundus; skin dissected from sac, and redundant sac and integument removed; suture of meninges by catgut, and of skin by wire. The wound healed by first intention, and the patient was discharged cured thirteen days after operation. The child was shown to the Society six weeks after with a linear scar where the tumour had been. All the operations were performed strictly antiseptically, the eucalyptus atmosphere being used instead of the spray. The points to which he would draw attention are—1. The principle of closing the meninges by bringing together two serous surfaces, as in peritoneal surgery, and superimposing separate skin flaps, the meningeal and skin lines of the suture not being apposite. 2. The great importance of observing strict antiseptic precautions, as a septic condition would probably end in the same way as these cases usually do when they spontaneously ulcerate—viz., by meningitis and convulsions. 3. The success attending the plastic operation in cases which are absolutely not amenable to any other form of treatment—e.g., where the coverings are thin, or the opening into the spinal canal large. 4. The possibility of transplanting periosteum, and its capability of surviving, as in the case read first. One may hope that the use of human periosteum—"e.g., from a recently amputated limb"—will give better results. 5. The successful issue of Case 3, where, although the sac was acutely inflamed, its complete removal with efficient drainage effected a cure. This case presents several points of pathological importance—e.g., (a) The rise of temperature without septicity apparently due to tension of, or pressure on, the great nerve centres. (b) The great relief given by aspiration. (c) Suppuration in the sac, possibly due to simple tension, probably not due to septicity, as the fluid was quite sweet on every occasion. (d) The entire absence of brain symptoms after operation, although the pressure on the great nerve centres must have been considerably interfered with during the time of healing of the wound. Mr. Robson suggested the following as a practical classification of cases of spina bifida for purposes of treatment—(1) Where no operation can or should be done. (2) Where no operation need be done. (3) Where an operation should be done. Class 1 (a) Where the deformity is very extensive, as in fissure of the whole or a considerable portion of the vertebral canal. (b) Where there is complete paraplegia. (c) Where the sac is large, the fissure extensive, and the coverings excessively thin up to the edge of the tumour, and no skin can be obtained to cover the meninges. But that such extreme examples even may stand a chance of cure is proved by Case 2. Class 2. Where nothing need be done. Where the sac is small and the coverings are so dense and firm as to form a good pad over the opening in the spinal column. Class 3. Where some operation should be done. (a) Where the sac only communicates with the spinal canal by means of a small opening; here it is a simple matter to dissect off the skin, expose the neck of the sac, ligature it by means of one circular ligature, and cut off the redundant meninges, bringing the skin over so as to have the line of skin sutures quite at the side away from the pedicle. Such an operation was performed by Mr. Ed. Atkinson, one of Mr. Robson's colleagues at the Leeds Infirmary. (b) Where the sac has a good skin cover and communicates with the spinal canal by a large opening, it is quite easy to perform the operation described in Case 1, carefully closing the meninges, and, if possible, placing the line of skin sutures away from the meningeal line of union. Such cases have been operated on successfully, not only by Mr. Robson but by Prof. Jessop, U.S.A. Human periosteum might be placed between the meninges and skin, but Mr. Robson is not at all sure that a thin plate of bone, if formed, would be very serviceable. If the expanded neural arches be large, he thought it might be feasible to bend them towards the central line, and by uniting them with thin silver wire, obtain a truly physiological closure of the spinal canal. (c) Where the coverings are excessively thin up to the margin of the tumour, as in Case 2, the operation is more difficult and uncertain, as the skin can only be obtained by a process of sliding from contiguous parts, and the tension necessarily present is not conducive to healing. (d) Where the spinal cord or the nerves are blended with the sac, he advises excision of portions of the redundant meninges at one or more places between the nerves, replacing the nervous structures in the spinal canal, and bringing over the skin cover; free drainage should be kept up between the membranes and integuments, or if this could not be done, the membranes might be punctured, the collapsed sac, with the nerves intact, being placed in the canal, and the skin cover made as before. It is important to remember that a silver or a leather shield should be worn over the site of the operation in order to protect the parts from injury, and to prevent the cicatrix from stretching or giving way.—The PRESIDENT said that the surgical treatment adopted by Mr. Robson gave surgeons an additional means of dealing with cases of spina bifida. He considered that there was not sufficient evidence to show that the method of injection was one which could be regarded as a good surgical procedure. He congratulated Mr. Robson on having been so successful in the four cases which he had treated. It was remarkable that the nerves were not involved in a large number of cases of spina bifida. The last suggestion with regard to the treatment made by the author was a good one. No doubt the committee now sitting on spina bifida would carefully consider the method of treatment advocated by Mr. Robson.—Mr. R. W. PARKER joined with the President in congratulating Mr. Robson on the successful results of his plan of treatment, yet he could hardly think that it would lead to results very much superior to those obtained by treatment of a less operative kind, for the lesion was a very profound one in many cases, such as no operation could rectify. An examination of the specimens in the London museums showed that the cord and its nerves entered the sac in upwards of 95 per cent. of all cases, a fact which itself contra-indicated excision of the sac wall; but if the sac wall were simply tucked in after the normal skin around its base had been detached, and, after more or less evacuation of the fluid, a satisfactory result might be obtained. The Society's sub-committee were just about to present their report, and, as a member of that committee, he would refrain from anticipating the conclusions which would be expressed in the report. He was sure Mr. Robson's paper would receive every attention. He might add that cases of cure by injection had been reported in which, as was found on post-mortem examination years later, the cleft in the spinal column was found to be very extensive. In the infant shown, although the sac was absent, there appeared still to be a soft fluctuating swelling over its former site.—Mr. RICKMAN J. GODLEE said it was evident that in the plastic operation of Mr. Robson there was no great risk of producing meningitis, and in this respect it seemed almost a safer method than injection with Morton's fluid. Reference was made to two cases which he had recently observed in which the injection of Morton's fluid was followed by the development of meningitis. In one case the child had convulsions, hemiplegia, and vesical paralysis; cystitis set in later on; the patient ultimately died. The occurrence of severe symptoms after surgical treatment might in some way be related to the frequency, with which some part of the spinal cord was involved in the sac, though in many cases the filum terminale could be the only part involved, and this was comparatively an unimportant structure. He spoke of a post-mortem examination which he had recently witnessed on a case of spina bifida in which the three or four lower sacral nerves were involved, and arose from points slightly to one side of the middle line, which he supposed was occupied by the expanded filum terminale of the cord. He said that Mr. Robson's was a line of treatment that would have to be carefully considered.—Mr. R. W. PARKER said that the spinal cord extended the whole length of the spinal column in intra-uterine life, and there was practically no filum terminale. Moreover, he had never succeeded in detecting the filum terminale in any specimen that he had examined.—Mr. MAYO ROBSON, in reply, believed that there were many cases of spina bifida into the formation of which no part of the spinal cord or nerves entered. It was impossible for distension of the filum terminale to give rise to the kind of sac which he exhibited, and which he had removed from one of his cases. With regard to the injection of Morton's fluid, in all the cases in which he had seen it used the result was fatal.

Dr. W. B. HADDEN read notes of a case of Choreiform Movements Supervening in Infancy and of Congenital Origin. The patient was a female, aged twenty-two; there was nothing to note in the family history, except that a sister died of fits at the age of ten months. The mother had had no miscarriages, but was said to have suffered from albuminuria for two months before the patient was born. Labour came on at full time, lasted twelve hours, and no instruments were used. Very soon after birth the child's head used to fall back, and she did not sit up like other children. There were no fits and no head injury. She never walked better than she does now. Movements were first noticed when the child was aged seven months, but did not attract serious attention until the age of two years. They have persisted ever since. She began to talk between the age of two and three years. Catamenia appeared at the age of fifteen, have always been regular, but scanty and painful. Patient is a short, stout, well-developed girl; is quite intelligent, reads fairly, but cannot write because of the condition of her hands. Her head is large and flat, but symmetrical; palate hard and a little arched; no deformity of spine. Movements very slight when lying down, and absent during sleep. They are at once noticeable on attempting movement, or if the patient be excited. The face and upper limbs are mainly affected. On trying to speak the face becomes contorted. The angles of the mouth are retracted, upper lip and alæ nasi raised, the forehead wrinkled, the eyelids partially closed. Hence, there are various and rapidly succeeding grimaces. An appearance of gaiety is followed by a frown, by a sniff of disdain, and by a momentarily lacrymose aspect. The speech is interrupted and the words brought out explosively. The muscles of the back and abdomen are unaffected. There are slight movements of the tongue. The fingers are flexed at the metacarpo-phalangeal joints, and extended at the phalangeal. But this position is not fixed. Fingers are often expanded, and there are simultaneous to-and-fro movements, suggesting athetosis, but more rapid and various. Some rigidity exists about the muscles of the arms and forearms. The muscles are well developed, and respond well to galvanism. Her grasp is feeble. Her legs are short, well developed, and as she lies in bed have very fair power. She cannot stand or walk without help. When supported she shuffles along, the legs overlapping, and the knees rubbing together, and the thighs being adducted. There is much resistance to passive movement of the legs; the tendon reflexes are probably exaggerated; there is occasional ankle-clonus; sensation, both common and special, is perfect; no loss of control over evacuations. The case belongs to a group which, though having individual differences, all possess one common feature, the spastic condition of the legs and the peculiar gait. The spastic paraplegia may exist alone, with or without affection of the arms, constituting Charcot's spasmodic tabes dorsalis, or infantile spasmodic paralysis. In two cases described by the author there were atrophic changes in the upper extremity. In addition to the present case he has seen two very similar instances. In connexion with the spasmodic paraplegia of infants other symptoms may be present, such as fits, mental defect, nystagmus, squint and inequality of pupils, deformity of chest, a symmetry of skull, delayed dentition, and defects of speech. The lesion in the case described was probably congenital, a porencephalous defect. Dr. Ross describes a very similar case, apparently due to injury in infancy. The author has never been able to satisfy himself that infantile spasmodic paralysis and congenital athetosis are dependent on injury either during or after birth. Treatment of various kinds was tried in the present case, but without benefit.—Dr. ANGEL MONEY thought that the case was interesting from many points of view. The presence of tonic and clonic spasms, with some impairment of the conduction of volitional impulses, in one and the same case, was instructive. It was suggested that tonic and clonic spasms were essentially due to differences in degree of innutrition of the nerve cells of the anterior horns, which energised the muscles. With regard to morbid anatomy, he considered that destructive lesions of any sort in any part of the pyramidal tracts could induce the symptoms of such cases.—Dr. HADDEN, in reply, said that some cases were of congenital origin, and some might be due to arrest of development of the fibres of the pyramidal tract which grew downwards from the large motor nerve cells in the cerebral cortex. In some cases the course of the cortico-medullary fibres appeared to be arrested high up in the brain; in other instances the paths were interrupted lower down. Cases had been put on record in which the spastic conditions appeared to be dependent on atrophy of the pyramidal tracts without any sclerotic change. That injury during or at birth may give rise to spasmodic paralysis seemed to have been placed beyond doubt by a case recorded by Ross. A case in which fits beginning in the paralysed arm were the first symptom was referred to; the legs were in a condition of spastic paraplegia.

Mr. JOHN R. LUNN read notes of a case of Calculus and Tumour of the Bladder. J. C——, aged thirty-five, married, a stoker by trade, was admitted into the St. Marylebone Infirmary on Sept. 8th, 1884. Four weeks before admission he noticed his water run away involuntarily, and had attended as out-patient at a hospital, where he was sounded. Two weeks before admission he was obliged to give up work and his urine became very offensive and thick. On admission, No. 10 catheter was passed, which gave the patient a good deal of pain; the urine was loaded with albumen and pus. The prostate was apparently enlarged. The patient was again sounded on Sept. 17th, when a stone was struck. Lateral lithotomy was performed on the 18th, and a large calculus removed from the bladder, weighing $1\frac{1}{2}$ oz., composed of oxalates, phosphates, and a little uric acid. In addition to the calculus a new growth was felt, which was too extensive to remove. The day after the operation the patient expressed himself much better and free from pain. Vomiting set in on the third day. He passed claret-coloured urine through the wound. The left kidney was noted to be enlarged two days before he died, on Sept. 26th. At the autopsy the wound in the perineum looked very unhealthy and showed no signs of healing. The bladder weighed 8 oz., was devoid of urine, and almost the entire surface was occupied by a new growth. No secondary growths were found. Both kidneys and ureters were distended with purulent matter. The right kidney weighed 8 oz., the left 14 oz. Mr. Lunn said that he was indebted to Mr. Eve for the microscopical account of the growth. The structure of the tumour had the character of a soft cancer, the cells were rather small and spheroidal, with large nuclei, and were in no part observed to be arranged in nests. In the softer parts of the tumour they were aggregated in large diffuse, small and rounded masses in spaces formed by a scanty stroma, while in the firmer parts the stroma was abundant and fibrous, and the cells formed elongated rods and masses.—The PRESIDENT remarked on the insidious nature of disease of the bladder. The connexion between growth and calculus was not very common. He referred to a case which had been under his care of papillomata covering every part of the mucous membrane of the viscus, and to another of extensive cancerous disease. He asked if there was much bleeding during the operation in Mr. Lunn's case.—Mr. LUNN answered in the negative.

Mr. RICHARD BARWELL read a paper on three cases of Pistol Shot Wound. The first case was that of a wound self-inflicted with a Derringer of $\frac{4}{10}$th-inch bore. The bullet passed through the seventh costal cartilage, the diaphragm, the stomach, and just notching the kidney, passed out of the abdomen between the first and second lumbar transverse process. The young man survived twenty-two hours. The case was introduced partly to show the power of these small pistols, but chiefly as evidence of the very little bruising which small conical projectiles fired at short ranges produce, there being no ecchymoses round any of the openings into the viscera, &c., save a very little at the kidney. The second case was that of a gentleman who shot himself with a pistol of under $\frac{1}{4}$-in. bore. The wound was within the areola of the left nipple; but the weapon must have been held obliquely, for the bullet, missing the heart, passed through about eight inches of the left lung and lay outside the chest near the lower angle of the scapula. There was very considerable hæmorrhage from the wound, and coughing caused the blood to be driven out several feet. There was also a good deal of hæmoptysis. Strict quietude, ice, acetate of lead, and opium subdued in about fifteen hours the external hæmorrhage, but the hæmoptysis continued for six days. Pneumothorax and hæmothorax, together with surgical emphysema, were very marked. Pneumonia supervened on the seventh day. After the lapse of three weeks, during which he had been in a very precarious condition, improvement set in, which steadily progressed. On the thirty-fifth day Mr. Barwell removed the bullet, which he had hitherto avoided doing, wishing the wound of exit from the chest to become closed previously. Seven weeks after the injury the man was discharged. The third case was that of a man who shot himself in the mouth and in the ear with a revolver, $\frac{1}{4}$-inch bore. The wound first named was on the left side of the soft palate, and, penetrating that part, inflicted another in the posterior wall of the pharynx. That bullet has never been found and has given no trouble, it is probably encapsuled among the deep muscles on the left of the spine. The other bullet passed for three-quarters of an inch down the auditory meatus without injuring it on either side, then continuing its transverse course, left that channel by a small wound at its posterior part. A probe passed in here touched a substance which Mr. Barwell believed to be metallic, exactly two inches from the margin of the meatus. The depth and direction of the wound delayed any attempt at extraction, because it appeared to Mr. Barwell that the projectile must lie in very dangerous proximity to the lateral sinus. After forty-eight hours, abundance of clear serum, which was either cerebro-spinal fluid or liquor cotunnii, became mixed with the blood discharged; the admixture of blood, then of pus, prevented any testing for sugar. The man, who was singularly apathetic, progressed favourably with the exception that a week after the infliction of the wound the parts about the angle and ascending ramus of the jaw swelled, and shortly after suppurated. On Dec. 4th there was in those parts sufficient disturbance to indicate that the projectile was producing considerable irritation, and ought, if possible, to be removed. Moreover, if, as seemed possible, the lateral sinus had been injured, the wound would in the five weeks have healed. With some difficulty, Mr. Barwell passed a Nélaton's probe sufficiently far to obtain the lead mark. Making a curved incision behind the pinna, he trephined the mastoid process to the depth of three-quarters of an inch; finding a small tract leading still deeper, he again got on Nélaton's probe the lead stain, but at a distance from the trephine hole of more than an inch. The track was cautiously enlarged with a gouge, a pair of sinus forceps passed down to the bullet, which, although very firmly fixed in the bone, was successfully removed. After this operation the man had no bad symptoms, the abscess in the jaw was opened, and the hole made by the trephine rapidly filled. All these men shot themselves, the pistols were therefore held very close, and they all used weapons the projectile of which is driven by the fulminate alone. In the last case the muzzle was on the skin, and in a medico-legal point of view it is important to note that there was no mark of burn nor of powder-tattoo. This, Mr. Barwell says, in his experience is the usual condition with weapons of that description. The other lessons from these cases are that small conical bullets discharged at short range bruise soft parts but very little, and though the projectile possesses very considerable velocity, the immediate result of such wounds, unless some peculiarly vital part be hit, is small.

Mr. **Mayo Robson** showed living specimens of two cases of Spina Bifida, which he had treated by plastic operation. Mr. J. R. **Lunn** showed microscopical sections of Tumour of the Bladder.

MEDICAL SOCIETY OF LONDON.

Treatment of Cervical Caries.—Necrosing Ethmoiditis and Mucous Polypi.—The Larynx in Tabes Dorsalis.

An ordinary meeting of this Society was held last Monday, Dr. W. Miller Ord, President, in the chair. The meeting was prolonged for half an hour.

Mr. **Walsham** read a paper on the Treatment of Angular Curvature of the Spine in the Upper Dorsal and Lower Cervical Regions by a combination of jacket and collar of poroplastic felt. The apparatus was made at Mr. Walsham's suggestion by Mr. Cocking. The apparatus, which is made of one piece of felt, consists of an ordinary poroplastic felt jacket, together with accurately fitting collar and helmet piece. The jacket and collar are continuous posteriorly, the collar portion being carried upwards over the occiput, and, after encircling the neck, is bent downwards over the shoulder and upper part of the front of the chest, where it overlaps the jacket portion, and is there secured in position by straps and buckles. The cases for which it is especially adapted are those where the caries is situated too high in the spine to be benefited by a common felt or plaster jacket, and too low to be treated by the various collars in use for cervical caries; in short, for cases in which the jury mast is now so frequently used. Mr. Walsham has not been satisfied with the results of the jury mast apparatus. The plaster-of-Paris jacket has no basis of support in the small pelvis of young children, and thus the jacket did not remove pressure from the diseased vertebræ. By means of the poroplastic apparatus the pressure is removed from the bodies of the vertebræ, though the weight might be transmitted through the posterior parts of the spine—i.e., through the articular processes and their supports. The results have been very encouraging. Several of the children who could not stand before the apparatus was applied were able to walk a few weeks later. The gravest objection to which it appeared open is that it is likely to embarrass thoracic breathing; but this is an evil incidental to all forms of jacket. The further advantages of this jacket over the jury mast apparatus were that, besides that it did not slip down in young children and males, the parts are held more steady, the rotatory and lateral movements of the neck in cervical caries are controlled, there are no straps to stretch or to be in different states of tension, according to the varying positions of the head, and the patient can lie down in greater comfort. Mr. Walsham advocated long daily periods of recumbency in the treatment of this form of caries. In conclusion, he urged the advantages of felt as a material for jackets generally, as against plaster-of-Paris. Sweat did not soften the felt unless the temperature reached 150° F. The shape could be well made and maintained. He proved that felt was porous by filling a hollow ball made of felt with smoke. The smoke slowly escaped through the interstices of the felt.—Mr. W. **Adams** thought nothing could be better than the apparatus shown by Mr. Walsham, though Dr. Sayre's improved plaster-of-Paris jacket was sufficient for the treatment of all ordinary cases. The recumbent posture maintained for a long period was of the utmost value; where paralysis supervened, he advised the recumbent posture with extension of the spinal column by means of a special apparatus. Reference was made to a case under his care in which complete motor and sensory paralysis supervened somewhat suddenly. Rest on an inclined plane with extension was followed by considerable and rapid improvement of the nervous disease.—Mr. **Noble Smith** said that the surgeon should attend to the application of the apparatus. Mr. Walsham relied not on extension, but merely on straightening the spine; in this way a sufficient amount of pressure was taken off. Paralysis might be relieved by this method of treatment. Recumbency in the prone position was most important; in a severe case in a child the prone position was spontaneously adopted.—Mr. **Clutton** referred to a form of apparatus, made of leather and iron of the same pattern as the poroplastic jacket of Mr. Walsham, which was in use at St. Thomas's Hospital. He considered that the apparatus with the jury mast was of no value. Recumbency was a most important point.—Mr. **Bernard Roth** spoke of treatment by passive extension of the spine. He asked how often ablution was performed in Mr. Walsham's patients, and what was done when caries existed high up in the neck. He had seen Fletcher's bags used with advantage.—Mr. **Walsham** said that no doubt recumbency was an invaluable mode of treatment; in disease of the first cervical vertebræ it was imperative.

Dr. **Woakes** read a lengthy paper on Necrosing Ethmoiditis and Mucous Polypi. He discussed the question of the relation of the diseased bone to polypi. The disease was extensive, and began as a chronic inflammation of the muco-periosteum lining the turbinate bones as well as the cells of the ethmoid bone; this inflammation of the soft tissues was associated with necrosis of the dissepiments of bones. The catarrh spreads from without inwards. His account of the disease was drawn from a record of eighty cases which he had collected in his experience at the Throat Hospital. As to the etiology, cold in the head, an exanthem (measles or scarlet fever), and blows were the usually assigned exciting causes. Sex showed but little difference. The disease was generally bilateral, the left side was more frequently attacked than the right; it occurred at all ages after puberty, and especially in young adults of either sex. A broadening of the bridge of the nose was sometimes produced. In the first stage the thickened muco-periosteum was rather pale, and could be seen to be hypertrophied, especially over the front of the middle turbinate bone. In the proliferating stage soft reddish fleshy growths were to be seen. Necrosis was always to be detected after the first stage of the disease had been passed. In some cases the hiatus semilunaris was a good deal enlarged. A probe might be passed in many directions, and dead bone struck in the anterior and posterior ethmoidal cells. The necrosis antedates the appearance of the mucous polypi. The myxomatous tissue proliferated near the surface of the muco-periosteum, no matter whether on the free surface of the turbinate bones or within the ethmoidal cells. There was no attempt at a new formation of bone. The characters of the polypi depend partly on their situation. The bones around the nose may be implicated, and so the base of the skull may be perforated, or the orbital wall destroyed at parts, and vision may be lost. The superior maxilla may become affected, and abscess of the antrum, or polypoid degeneration of its lining membrane, take place. In the third stage of the disease thin plates of atrophied bone may be found in the midst of an exuberant polypoid excrescence. The disease, as a rule, tends steadily to progress. Mr. Edgar

Thurston had prepared many microscopical sections illustrative of the pathology of the disease. These specimens and many drawings were shown to the Fellows of the Society.—Mr. Spencer Watson asked whether the conclusions were taken by Dr. Woakes as applying universally to mucous polypi. It was difficult to understand that necrosis could have preceded the appearance of all polypi. He said that Professor Silvercandle had shown that one in eight individuals suffered from nasal polypi. He believed that obstruction in the nostril due to posterior rhinitis, or to deviation of the nasal septum, or to chronic hypertrophic rhinitis of the middle turbinate bone, was a frequent cause of nasal polypi.—Mr. Cresswell Baber thought that nasal polypi were not always preceded by necrosis or even accompanied by it. The turbinate bones vary in size in different individuals, and it might be difficult to say whether a turbinate bone was of normal size or not.—Mr. Stoker concurred with the views of Dr. Woakes.—Mr. W. Pye said that on examining the nose with a probe in cases of nasal polypi in children, he had nearly always struck dead bone.—Dr. Woakes said, in reply, that he could not say that necrosis was invariably the precursor of nasal polypi; all he could say was that he had never examined cases of polypi without detecting necrosis. The necrotic spicules are formed *pari passu* with the development of mucous tissue. A normal middle turbinate bone was a rare structure.

The President and Dr. Semon showed a case of Locomotor Ataxy, with bilateral incomplete paralysis of the abductors of the glottis openers, which they believed was more frequent than was ordinarily supposed. This stenosis of the glottis had gone on under observation, and was unaccompanied by any obvious symptoms. The larynx ought to be examined in all cases of tabes dorsalis. Charcot, McBride, and Ernest Jacob of Leeds had described similar cases of abductor paralysis. A primary rigidity of the glottis muscles was believed in by some German authorities, who said they had never seen a progressive development of the stenosis; these views were refuted by the present case. Tracheotomy might have to be resorted to ere long, and the patient had had several attacks of laryngeal obstruction, which at times threatened tracheotomy.

HARVEIAN SOCIETY OF LONDON.

Early Treatment of Concomitant Squint.—Resection of the Intestine.

A meeting of this Society was held on the 19th ult., the President, Dr. T. Morton, in the chair.

Mr. W. Adams Frost read a paper on the Early Treatment of Concomitant Squint. The author submitted that in practice the truth and importance of the following propositions were not sufficiently recognised:—1. This form of squint seldom recovers spontaneously. 2. It leads, in a few months, to very great impairment of the vision of the squinting eye. 3. The majority of the cases can, in the early stages, be cured by correcting the hypermetropia with glasses. The binocular character of this form of strabismus, and the distinction between a "fixed" squint and an alternating one, were briefly illustrated by means of Mr. Priestley Smith's model. The popular notion that children squint from imitation or caprice, and that they grow out of it, was entirely erroneous. Among the cases treated at St. George's Hospital during the last four years, 60·5 per cent. presented amblyopia of the squinting eye. Amblyopia never appears while the squint is alternating. Of the cases in which there was no amblyopia in the above series, 41·6 per cent. were alternating. It commenced directly the squint became fixed. Hundreds of eyes were lost every year from neglected squint. If, when all accommodation was rendered impossible by the application of atropine, the squint disappeared, it would almost certainly cease by correcting the hypermetropia. Spectacles could be given at a very early age; Mr. Frost had often ordered them for children under four years, and had never found reason to regret having done so. When a child was too young to wear glasses, treatment might be postponed if the squint was really alternating; if it was fixed, either an operation was necessary, or the other eye must be covered to save the squinting eye from amblyopia.

Mr. Frederick Treves then read a paper on Resection of the Intestine. The operation in question dated from about the year 1878, although many isolated instances had been recorded much earlier. Some 150 cases were now on record. The operation was applicable to both the small and the large intestine, and had been performed for the following conditions:—(1) Single and epitheliomatous strictures; (2) neoplasms other than cancer; (3) extensive matting of the bowels, involving obstruction; (4) irreducible intussusceptions; (5) gunshot and allied injuries of the bowel; (6) gangrenous gut in hernia; (7) fæcal fistulæ. It might also be applied to certain perforating ulcers of the intestine. The operation implied merely the application to the intestine of a simple and recognised plan of treatment which was adopted in corresponding conditions to other parts of the body. In most of the affections named, enterotomy and colotomy offered the only other means of treatment; they gave temporary relief only, leaving the cause of the disturbance untouched. In another series of cases the removal from the body as early as possible of gangrenous and putrid parts was obviously indicated. Lastly, the mortality in gunshot wounds of the bowel was so exceedingly high that the operation had in these cases great claims to consideration. The *modus operandi* was illustrated by enterectomy. There were two procedures. In one, the divided ends were united by sutures immediately after the resection; in the other the part was excised and an artificial anus established, which was closed after a time by a second operation. The abdomen having been opened, the loop to be excised was drawn out and placed upon a sponge. The gut above and below was severed either by the fingers of an assistant or by special clamps introduced by Rydygier, Bishop, Makins, and Treves. The gut was excised, and with it a triangular piece of the mesentery, the cut edges of the latter being united by a few points of suture. If the bowel was to be united, the best material was Chinese twist applied by Hagedorn's needle and needleholder. Of the various sutures, the Czerny-Lembert was the best. A row of sutures was introduced involving only the mucous membrane, and a second row involving only the peritoneum. Some fifteen points of suture were needed for the first row, and about twenty-five for the second. Of the two methods, the second was by far the better. Most of the patients were not in a condition to bear a protracted operation. Moreover, the first method did not give complete relief to the obstruction, did not ensure emptying the bowel above the obstruction, and involved great risk from fæcal extravasation owing to the distended state of the gut and to the great risk of gangrene along the suture line. Besides,,there was great difficulty in uniting the much dilated upper segment to the shrunken segment below. The mortality of the operation was discussed, its simplicity urged, and a hope was expressed that its application would be cautiously and more widely extended.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Prevention of Heat Apoplexy.

At a meeting of this Society, held on the 11th ult., Dr. Norman Chevers, President, in the chair,

Surgeon-General A. C. C. De Renzy, C.B., read a paper entitled the Prevention of Heat Apoplexy, of which the following is an abstract:—The object of this paper was to apply Indian experience in the prevention of heat apoplexy among the troops in the Soudan. The writer resided for many years at the Multan in the Punjab, one of the hottest places in the world, and saw a great deal of heat apoplexy amongst the British troops and railway *employés*. In the month of June the temperature in the shade rises to 120° F., and a black bulb thermometer registers 176°. An ordinary thermometer, exposed in the sun's rays, registers 157°. The dryness of the air is extraordinary. The mean humidity of May is only 26°, and the maximum humidity is as low as 17°; saturation equal to 100°. Dust storms occur at very short intervals all through the hot weather. The nights are comparatively cool. In June, the hottest month, the minimum thermometer goes down to 71°. About 10 o'clock the sky becomes perfectly cloudless, and the earth radiates the heat stored up during the daytime rapidly. But there are usually three or four intensely hot nights in the year when the clouds do not disperse, and so radiation is obstructed. On such occasions the writer has found his bed so intensely hot that he had to have it sprinkled with water to make it tolerably cool. The mean daily range of May is 34·43°. The climate of the Soudan is several degrees cooler than that of Multan, and not at all so trying, and, as experience shows that a very fair standard of health can with suitable arrangements be secured for British troops at Multan, it is reasonable to hope that, so far as high temperature is concerned, a similar result may be attained in the Soudan. Contrary to what might have been expected, Multan has long been one of the healthiest stations in Northern India. Taking the returns of the last eighteen years, it stands fifth in the order of healthiness. Bareilly stands first, with a death-rate of 12·01 per 1000. Fort William second, with a death-rate of 12·33 per 1000, while the death-rate of Multan was 15·15 per 1000, or actually lower than the death-rate of the troops stationed in England was thirty years ago. If the mortality from heat apoplexy were reduced, as it might be, Multan, notwithstanding the intense heat of its summer, would be one of the healthiest stations for British troops in the world. All through the summer of 1848 the fort of Multan was invested by British troops, who had little sickness and few casualties from heat apoplexy. Lord Gough, who was Commander-in-Chief in India at that time, was altogether opposed to the operations being carried on in the summer, as he thought it impossible that the troops could withstand the heat. The result proved that his apprehensions were unfounded. With good tents, a good commissariat, and arrangements well adapted in other respects for the protection of the health of the troops, the campaign was brought to a brilliant close by the capture of the fortress, one of the strongest in India. Heat apoplexy causes a large number of deaths among the troops; taking one year with another about 100. Heat apoplexy occurs through very different circumstances—(1) under exposure to the direct rays of the sun; (2) under exposure to great heat in the shade. The deaths under the second head are far more numerous than those under the first. For the prevention of heat apoplexy, especially under exposure to the direct rays of sun, two things are indispensable —(1) that the clothes be loose and light, so as not to interfere with the free movements of the chest and evaporation of the skin, and so as not to obstruct the cervical circulation, and (2) that a supply of drink should always be at hand to relieve the first signs of thirst. The importance of these precautions was illustrated by several striking cases that fell under the writer's notice. At the capture of Rangoon in 1852, of two sets of men who were alike in all other respects, one fought in shirt sleeves under an intensely hot sun, the other in blue cloth tightly fitting coats; many of the latter began to drop down insensible shortly after coming into action, their commanding officer being among the number. The want of water causes great loss of life from heat apoplexy on first service in India. The arrangements for the supply of water are most defective. Natives use immense quantities of water under exposure to the sun, and to this practice was attributed their immunity from heat apoplexy. While the deaths from this disease among the British troops were 20 per 10,000 of strength, they were only 2 per 10,000 among native troops. Heat apoplexy is very rare among officers, who are careful about their dress, and also to have something at hand to relieve thirst. Sportsmen who go out shooting in the hottest weather suffer very rarely. And the disease is unknown among Assam tea-planters, whose business requires them to expose themselves in the sun in the hottest season and at the hottest time of the day. The great majority of the cases of heat apoplexy among soldiers, due to exposures to great heat in the shade, occur between sunset and midnight. This was attributed to the peculiar meteorological conditions of that period of the day in conjunction with the crowding of the men in the canteen. The breeze es away; clouds form, obstructing radiation; and while s lasts the men crowd in dense masses into the canteen, ventilation of which is altogether inadequate for the ber of men who temporarily occupy it. Crowding, even hough it is only for a short period, is most dangerous when the air is very hot. The danger is much increased when, to the crowding, excess in the use of alcohol is superadded. The barracks in the evenings become as hot as ovens. As a means of cooling the barracks it was proposed that they should be douched every evening after sunset. With the present barbarous system of water-supply this suggestion would be impracticable, but if the troops are to be protected against the ravages of cholera and typhoid fever, water must be provided under pressure, as it is in more civilised countries. This proposal when made some years ago had the approval of Mr. Edwin Chadwick, but it was found impossible to give it a trial. In conclusion, it was contended that experience in the hottest parts of India warrants the hope that under good arrangements the losses from heat apoplexy among the troops in the Soudan may be kept within very moderate limits. With good tents of the Indian pattern, attention to clothing, good arrangements for the supply of water, avoidance of overcrowding, especially in tents or huts, and extreme moderation in the use of alcohol, for which tea should be substituted, the losses from apoplexy would be very small.—In the discussion which followed Sir William Smart, Drs. Murray, Scriven, Lloyd, White, Lawson, Cullimore, Comyn, and Squire, and Mr. Shirley Murphy took part.

MEDICAL OFFICERS OF HEALTH SOCIETY.

A MEETING of the above Society was held on Friday, March 20th, Dr. J. Orme Dudfield, President, in the chair.

Mr. A. WYNTER BLYTH read a paper on the Action of Disinfectants on Microzooids. The author enumerated the diseases of animals and men which may be considered beyond a doubt to have an intimate connexion with microzooids—viz., mouse and rabbit septicæmia, a fatal disease of the guinea-pig produced by the micrococcus tetragenus, the anthrax of animals and men, fowl cholera, glanders, malignant œdema, bovine and human tuberculosis, erysipelas, some forms of pneumonia, and acute osteo-myelitis. On the other hand, it had not been proved satisfactorily that diphtheria, scarlatina, relapsing fever, cholera, typhoid fever, and some others were due to microzooids, though the balance of evidence seemed to be in favour of such a view; probably zymotic diseases would come to be recognised as consisting essentially of the invasion of the tissues of individual megazooids by legions of microzooids. The term "disinfectant" the author used throughout as synonymous with "germicide." A colony of microzooids submitted to a solution of a true disinfectant, and then having been freed from the disinfectant and put into the best possible conditions for development and growth, showed no signs of life; the colony had been disinfected—that is, killed. Hence, according to this view, disinfection is either a destruction of pathogenic microzooids or a poisoning of them; the end effected being for practical purposes the same. The author then briefly detailed his own experiments on spore anthrax published in the Royal Society of Edinburgh's *Transactions*, and summarised the experiments of Schiff and Fischer on phthisical sputum, and those of Fischer and Proskauer on the action of chlorine and bromine. The author had made some observations on mouse septicæmia; threads were infected with mouse septicæmia and soaked for half an hour in Tuson's disinfectant, a saturated solution of sulphate of iron, a 10 per cent. alcoholic solution of cresylic acid, a 10 per cent. solution of sulphenic acid, a 10 per cent. solution of chlorozone, and a strong solution of chloride of zinc. The sulphenic acid and the alcoholic solution of cresylic acid disinfected perfectly the thread; but of the other agents some had no effect, others superficially disinfected. His most recent researches were on the pyridine bases. He had raised a pure cultivation (from the last stages of nasal catarrh) of a yellow bacillus which liquefied gelatine; the liquid gelatine then becoming yellow and fluorescent. This bacillus produced spores of moderate resistance, was not pathogenic, and grew with rapidity at ordinary temperatures. Threads infected with this yellow bacillus were soaked in a 1 per cent. solution of pyridine, collidin, lutidine, and acridine, and then, having been freed from the disinfectant, they were brought up on nutrient gelatine; the threads were found to show no signs of growth around them, whereas the "control" threads grew rapidly. The antiseptic power of pyridine was tested on the organisms found in sour milk, and pyridine was shown to inhibit growth. Since the pyridine bases are present in tobacco smoke, the smoke from an ordinary pipe of tobacco was passed through water, and the resulting solution was found to be, so far as the yellow bacillus is concerned, strongly disinfectant. The results of experiments with the yellow bacillus, when treated with solution of morphine, strychnine, atropine, and other alkaloids, were also given, from which it would seem that strong solutions will kill the bacillus. Turning to the practical aspect of the question, the author summarised the general conclusion to be drawn from these researches. Disinfectants, when they are not destructive agents, act as poisons; they poison the microzooid in a manner not essentially different from the lethal poisoning of a higher life form, and this is the reason why such poisonous substances as corrosive sublimate, carbolic acid, and chlorine are most to be relied upon. It was evident that to perfectly disinfect, the element of lime must not be disregarded; to receive the specific excreta in a strong solution of sulphate of iron or of carbolic acid, and then within a few minutes cast the excreta into a drain, could only superficially disinfect, and such excreta might in many obvious ways again become dangerous. He considered that the best and most efficient way to disinfect a room after disease was:—First, to make it as much as possible like an hermetically sealed box, and in this box to evolve chlorine; 3 lb. of chloride of lime and 3 lb. of hydrochloric acid for every 1000 cubic feet of space. The chloride of lime was to be divided into several distinct parts in deep vessels, and to be placed as high in the room as possible; the hydrochloric acid was to be mixed with the chloride of lime gradually in the manner described by Fischer and Proskauer. The room was to be kept closed for twenty-four hours. Secondly, all things in the room capable of being submitted to a moist heat were to be taken away to a suitable apparatus. Thirdly, the floor was to be washed with a solution of corrosive sublimate (1 in 1000). The principles of this process had been carried out in the parish of Marylebone for more than a year, and the author considered the method the best at present known.—In the discussion which followed, the President, Dr. Iliff, Dr. C. E. Saunders, Mr. Kingzett, and Drs. Moore, Corner, and Willoughby took part. Mr. Wynter Blyth replied, and the meeting was adjourned.

ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Sub-section of Public Health was held on Feb. 5th.

The PRESIDENT (Dr. J. W. Moore) delivered an inaugural address on the Relations of the Medical Profession to the Sanitary Organisation of Ireland. He contended that the medical aspect of that organisation has signally failed, mainly from two causes—want of supervision and inadequate remuneration. The Public Health Act, 1878, gives only a permissive power (Sec. 2) to the Local Government Board to provide supervision, and naturally this power in consequence has not been exercised. Again, the remuneration allowed to medical officers of health by the various sanitary authorities under the sanction of the Local Government Board is, except in a very few instances, so shamefully inadequate that the only possible result is practically to render the Act a dead letter so far as medical inspection or advice is concerned. Accordingly, he recommended (1) that the Local Government Board, acting as the supreme sanitary authority, should divide Ireland into a suitable number of districts for purposes of sanitary inspection; (2) that each of these districts should be subject to the supervision of an inspecting medical officer of health, or, as such an officer is called in Sec. 11 of the Public Health Act, a medical superintendent officer of health; (3) that the dispensary medical officer should still act as district medical officer of health, reporting as occasion may arise, not directly to the local sanitary authority, but to the inspecting medical officer of health for his district; (4) that the Local Government Board, and not the local sanitary authorities, should appoint the inspecting medical officers of health; and (5) that these officials should be sanitary experts, independent of the local authorities, and reporting from time to time to the Local Government Board. As to remuneration, the inspecting medical officers of health should be paid, by the Treasury alone, a salary which would enable them to forego private practice, in order to devote their whole time and talents to the discharge of their very responsible and very onerous duties. The district medical officers of health should be paid, in equal shares by the Treasury and by the local authorities, a suitable salary, not a nominal one, subject to a minimal but not to a maximal scale—i.e., a salary which should not be less than a fixed amount, say one-half their salary as dispensary medical officers.—On the motion of Dr. CAMERON, seconded by the REGISTRAR-GENERAL, thanks were voted to the President for his address.

Dr. E. MACDOWEL COSGRAVE read a paper on Sewer Gas and Disease. He pointed out that in spite of the Dublin-street sewers being well ventilated, it is certain that if imperfections exist in the house-drain, sewer gas will enter, as the outer air is generally denser than that in houses and as the updraught of fires causes a strong suction. At present many houses have rubble drains, which are always imperfect, and of the pipe-drains many are defective, and hardly any houses are properly disconnected from the street sewers, dependence being placed upon water-traps, which are untrustworthy as excluders of sewer gas. The remedy is to have a properly set pipe-drain cut off from the sewer by an intercepting trap, and ventilated by openings at each end at different levels, to cause a constant current of air. Occasional flushing with a sudden forcible rush of water will render such an arrangement almost perfect. Sewer gas seems to affect health in two ways: (1) As a direct poison, causing sore-throat, diarrhœa, &c.; and (2) by devitalising the oxygen of the air, and so leading to anæmia, lassitude, depression of spirits, &c. The symptoms often show first in servants who sleep in the basement. Surgical operations and confinements are specially liable to be followed by mischief if sewer gas can find entry. The Sanitary Protection Department of the Dublin Sanitary Association affords a reliable means of examining into house drainage, and the engineer to the department (Mr. W. Kaye Parry, M.A., C.E.) states that the following grave sanitary defects were found in some of the houses he examined:—Rubble drains under house, 26 per cent.; defective pipe drains, 61 per cent.; drains not intercepted from sewers, 65 per cent.; unventilated drains, 75 per cent.; waterclosets objectionable, 83 per cent.; soil-pipe leaking, 44 per cent.; scullery dangerously trapped, 50 per cent. In many cases disease accompanied the foregoing defects, especially enteric fever, diphtheria, and illness after confinements. Medical men ought, in the interests of preventive medicine, to have drains, &c., put right before outbreaks of illness, and not wait for illness to call their attention to defective drainage.—Dr. CAMERON gave several instances of defective drainage, and said in reference to exhalations from ventilators, experiments proved there was an influx of air into drains in the morning when fires were lighted.—Dr. GRIMSHAW, registrar-general, remarked that instances came under his notice of the defective line and falls in some of the public sewers in Dublin, and the consequent difficulty in obtaining sufficient falls in house drains in some localities. There was a case where the engineer of the Sanitary Association was unable to provide a complete and efficient system of house drainage in a particular place, because the level of the street sewer was not sufficiently below the level of the floor of the basement storey of the house. In this case it was impossible to put in an intercepting trap.—Surgeon-Major HAMILTON mentioned the steps he took for the ventilation of the barrack sewers of Dublin garrison.—Dr. Doyle, Dr. Henry Kennedy, and the Chairman having taken part in the discussion, Dr. Cosgrave replied, and the Sub-section adjourned.

Reviews and Notices of Books.

Conferences on Education: International Health Exhibition. Vols. XIII., XIV., XV., and XVI.; Sections A, B, C, and D.

THE main value of the educational section of the Health Exhibition consisted in the conferences between British and foreign educationists. Much interesting information was given, and some novel views and theories were discussed. It may appear strange, however, that there should have been such a dearth of medical opinion. We think only four members of the profession spoke at all, none of them frequently.

Although most of the speakers on female education appeared to understand the importance of due attention to the physical welfare of the scholars, some of the suggestions strike us as ill-considered—e.g., the Rev. Canon Holland, who spoke of the importance of ventilation of school-rooms by raised sash frames and Tobin's tubes, had apparently become oblivious of sanitary considerations when he went on to remark: "A glass house, just large enough to hold a piano and a chair, and erected in the corner of a class-room, makes it quite feasible to have two instruments in one room. In our Baker-street school we have two glass houses in one room, and three pianos, which are all played at the same time without any collision of sound." It would be interesting to know whether the air in this school has become scientific enough to pass through the glass houses which effectually keep out sound, or whether there is some provision for ventilating these chambers from the outside, and if so of what nature, as from their small size—about 100 cubic feet, we gather from the description—they must require a peculiarly efficient apparatus for the purpose.

We could have wished for further information from Miss Freeman as to the exact duties and powers of the female physicians whom she says all the colleges for women in America employ, and who are "salaried to keep the students well." She significantly adds that they lose their appointments if they do not do so. Can these advanced institutions have taken a leaf out of the social customs book of the "Heathen Chinee"?

The German gymnastic system was referred to by Mr. J. Holm, F.R.C.S.E., as having been productive of great good in developing "manliness." He also remarked on Ling's system, which recognises the necessity of a knowledge of anatomy in the teacher of gymnastics in order that some muscles should not receive an undue development to the detriment of other parts of the body; but that all parts should be brought equally into play, and thus equal circulation, distribution of nerve power, and nutrition should be set up. The Royal Gymnastic Institute at Stockholm requires from persons desirous of obtaining appointments (to teach gymnastics) at public schools a course of study, including lectures on anatomy, physiology, pathology, and hygiene, together with instruction in the theory and practice of gymnastics, educational, military, and medical. Physicians by a modified course can obtain a diploma enabling them to practise medical gymnastics.

Many striking instances were given of the advance in intelligence of young children under the Kindergarten system, but we should scarcely desire one of our own children to exhibit such precocity as the little boy, aged five, whose mother wrote to Mr. Fitch that he "told a builder that his mother would not take his house, and on being asked why, he replied, 'You have not disconnected your drain-pipe.' He then explained that the drain-pipe ought to be cut off with an open gully underneath."

Notwithstanding many divergencies of opinion about minor matters, it is gratifying to note the substantial agreement of most of the speakers with the views expressed by the "Lancet Commission," published in 1875, which we believe paved the way for the many reforms in school hygiene which have been established since that time.

OUR LIBRARY TABLE.

St. Thomas's Hospital Reports. New Series. Edited by Dr. S. J. SHARKEY and Mr. FRANCIS MASON. Vol. XIII. London: J. and A. Churchill. 1885.—The contents of this volume are varied, and contain many original articles, of which the following must be noticed:—Vegetable Growths as Purifiers of Sewage, by A. W. Bennett, M.A.; A Case of Osteitis Deformans, by John R. Lunn; Two Cases of General Atrophy treated by the "Weir Mitchell" Method, by Seymour J. Sharkey, M.B.; Case of Gastro-Colic Fistula, by W. Edmunds, M.D., F.R.C.S.; Cases of Tubercular Meningitis, by J. S. Bristowe, M.D.; Mediastino-Pericarditis, by H. R. Hutton, M.B.; Four Cases of Symmetrical Development of Fat, by Sir William Mac Cormac; Cases of Ulcerative Endocarditis, by R. Percy Smith, M.D. The Medical Report for 1883 has been drawn up by Dr. Hadden, and the Surgical Report by W. H. Battle, F.R.C.S.

Lewis's Practical Series: Dental Surgery for General Practitioners and Students of Medicine. By ASHLEY W. BARRETT, M.B. Lond., M.R.C.S., L.D.S. London: H. K. Lewis. 1885.—A book of this kind has long been wanted, but it can scarcely be said that this one fully supplies the want. It seems chiefly to fail in its lack of illustrations. Though the description of operations is fairly good, yet Mr. Barrett too often forgets he is addressing medical practitioners, and writes as though his readers quite understood all about excavators, chisels, and the various instruments familiar to the dental surgeon. Perhaps in future editions this defect may be remedied, but even in its present form this book will be of distinct use to those for whom it is intended, as it contains in brief and readable form, though in rather long-winded sentences, much useful and practical instruction. Mr. Barrett's views on caries are crude, but his directions as to the treatment of it are very plain, though, as already intimated, they would be much helped by a few good illustrations. One sentence in the chapter on anæsthetics cannot be too highly commended; it reads: "The undesirability of employing any anæsthetic, be it 'gas,' ether, or chloroform, without the presence and assistance of a companion, who should be a qualified medical practitioner, needs hardly to be indicated." Of course this means in addition to the operator, be he surgeon or dentist.

The Ship Captain's Medical Guide. Compiled by the late HARRY LEACH, M.R.C.P., and revised by WILLIAM SPOONER, L.R.C.P., M.R.C.S. Ninth Edition. London: Simpkin, Marshall, & Co. 1885.—This edition has been revised throughout, and whilst the general plan of the work has been maintained, extensive additions and alterations have been made. The chapter on the Prevention of Disease has been entirely rewritten, an account of some diseases not previously mentioned has been inserted, and an endeavour made to bring the treatment up to the standard of the present day. The work, which is written solely for the use of masters and mates of vessels at sea, is confined strictly to a plain and brief description of accidents and diseases that occur on board ship; and much care has been taken to show, as clearly as possible, how these accidents and diseases can be best treated by a non-professional man.

Medical Reports of the Chinese Customs Service. Compiled and arranged by Surgeon-General C. A. GORDON, M.D. London: Baillière, Tindall, and Cox. 1884.—The publication of the medical reports, an epitome of which is contained in the laborious work which we now briefly notice, was first suggested by Dr. Jamieson of Shanghai. Surgeon-General Gordon has compiled a summary of the reports. A perusal of the list of contents of the volume before us is sufficient to show how varied and extensive the subjects treated by the medical officers connected with the Imperial Maritime Service of China have been. The information relating to the state of health of foreign residents at the several treaty ports is very valuable, and will be of service to those who contemplate proceeding to that vast country. The section of the volume dealing with materia medica is a valuable collection of information regarding the general use of medicines in China. The appendix contains a vast amount of information on many subjects, and notably on the prevalence of epidemics from the earliest times; a sort of medical diary dating back from B.C. 224 has been compiled at the cost of immense labour and patience, giving a chronological record of prevailing pestilences in China, as well as of epidemics and natural phenomena, such as earthquakes, inundations, and famines, in other parts of the world.

Seasonal Map.—We have received a copy of a seasonal climatic map of the United States, graphically illustrating combined humidity statistics with isotherms, wind statistics, and seasonal tables, compiled from data of the Signal Service Bureau by Charles Denison, A.M., M.D., Professor of Diseases of the Chest and of Climatology in the Medical Department of the University of Denver. Tables for computing the comparative dryness and moisture of localities are also given. By the colour shades in which the map is printed are represented even divisions of the climate of the United States, starting from the mean for the whole country, as determined by the combined humidity statistics. The map represents a marvellous amount of labour, and cannot fail to be of great value to meteorologists as well as to officers engaged in sanitary administrative work in the United States.

Ellis's Irish Education Directory and Scholastic Guide for 1885. Dublin: E. Ponsonby. London: Simpkin, Marshall, and Co.—This book, which is now in the fourth year of its issue, contains full information as to the Irish universities and professional schools, and the institutions in Ireland for promoting intermediate, technical, and primary education, with complete alphabetical lists of Irish colleges and schools, and copious alphabetical and classified indexes. The part of the book relating to national education has been entirely remodelled, so as to make it a complete guide to the national system. It will prove useful to all who are in need of the information it is specially designed to afford.

We have received the second volume of the *Dictionary of National Biography*, edited by Leslie Stephen. It extends from Annesley to Baird, and from every point of view is fully equal to its predecessor, which we noticed favourably in a recent issue.

Analytical Records.

THE PURE WATER COMPANY.

In spite of modern sanitary reform, the water-supply of country places, and even of many towns, is still so unsatisfactory that the production of aerated beverages absolutely above suspicion is a matter of some difficulty as well as of great importance. In the strictest sense of the term pure water is as yet unknown to us. Even Stas, who, after chemical treatment, rectified the water used in his celebrated stoichiometrical determinations, twelve times from a platinum still, did not attain perfection. But a visit to the works of the Pure Water Company at Battersea will convince anyone that practical purity can be attained with the appliances which modern chemical and engineering science have provided. In these works water is first distilled by the powerful apparatus invented by the late Dr. Normandy, and greatly improved of late. It is extensively used in ships, and is, we understand, doing good service in the present Egyptian campaign. Nine thousand gallons a day can be obtained from the engine in the works. We analysed a sample of this water, and obtained less than half a grain per gallon of solid matter, which, as every chemist will understand, is practically nothing. This extremely pure water has, however, like all distilled water, a peculiar smoky taste. To remove this taste it is passed through an animal charcoal filter. How the animal charcoal acts is not very clear. The filtered water proved on analysis to contain about four grains and a half per gallon of solid matter, chiefly phosphate of lime. It was free from the flat and smoky taste of the distilled water, and we need not say that, dietetically, it was perfectly pure. No other water is used in the works.

Carbonic acid is prepared by a continuous process in a very large pair of Mondollot generators, made by Mr. H. Favarger of London. In this apparatus, which possesses considerable advantages over all others, the sulphuric acid is introduced by a leaden syphon, which ensures regular action and avoids all waste. The gas passes through two washers, the second of which is a glass globe in which the transmission can be watched, the aeration being afterwards effected in the usual manner. Every care has been taken to avoid the possibility of mineral or other contamination, and it is certain that no purer or more trustworthy beverage could be produced.

Considerable variety is, of course, introduced into the articles sent into the market. First, we must notice Puralis, which may be described as filtered and aerated distilled table water. Then there are the usual soda and potash waters, each of which was found by analysis to contain the proper quantity of the alkaline carbonate. More novel are the aerated quinine water, which contains in each bottle a definite quantity of the soluble sulphate, and the ginger ale, ginger punch, and ginger gin. These last are excellent preparations, which will be valuable to the army of temperance advocates, inasmuch as they are not only pleasant in themselves, but they suggest alcoholic flavour without containing alcohol.

"THE METAPHYSICS OF NATURAL HISTORY."

To the Editor of The Lancet.

Sir,—Accept my thanks for your comments in your last issue on my lately published lecture on the above subject. That lecture is there regarded almost exclusively as an endeavour to reconcile religion and science. That such may be its tendency, I earnestly desire. But to readers of your journal, and to students generally, there is a preliminary and more immediate question. How far are we entitled to declare that there must be a certain form of energy, directivity, or determinism existing in the field of nature, which can be so tracked, step by step, from the commonest physical changes, through elementary biologic provinces into the territories of reflex action, instinct and deliberate intelligent volition, that its unity of nature is beyond dispute? That however humbly or highly developed, or differently conditioned in its modes of expression, it may be, this energy of governance is one and the same? How far must the doctrine of correlated forces be modified so as to embrace what would now be called metaphysical causation? An influence, quite outside any will of its own, determines the sex of a child before its birth. At ten years old that same biologic influence is impressing modifications upon the characters of the child through its bodily constitution; it is a boy in mind and will, because it is a boy in body; at thirty years old intelligent volition has assumed predominance; but we know well enough how deeply all is still dependent on purely biologic antecedents. Here, then, is change simply biologic eventuating in intelligent will-force without a discoverable break. And more, the original life-movement may itself be traced backwards and found rooted in physico-chemical conversion of food; and in an upward direction we go on step by step to emotions, affections, and moral cerebration. This continuity may be inexplicable, but is it not certain? Again, in my tiny book I have dared, *rubesco referens*, to assume that there may be some truth in electro-biology, absurdly so-called, and in spiritualism, equally misnamed. Where more hopefully than among the mass of your readers may one seek for assistance on this point? Can any of them produce evidence that will-force can, or will, accomplish physical results? Your friendly criticism, and that of others, has shown that these views of the subject have been inadequately brought forward in the lecture. A page or two of appendix may somewhat remedy this in a new series now preparing by Messrs. Lewis.

I am, Sir, yours obediently,

March, 1885. Stephen Monckton.

Royal Institution.—The following are the lecture arrangements after Easter:—Professor Gamgee: Eight lectures on Digestion and Nutrition, on Tuesdays, April 14th to June 2nd. Professor Tyndall: Five lectures on Natural Forces and Energies, on Thursdays, April 16th to May 14th. Professor Meymott Tidy: Three lectures on Poisons in relation to their Chemical Constitution and to Vital Functions, on Thursdays, May 21st, 28th, and June 4th. Mr. W. Carruthers: Four lectures on Fir Trees and their Allies in the Present and in the Past, on Saturdays, April 18th to May 9th. Professor Odling: Two lectures on Organic Septics and Antiseptics, on Saturdays, May 16th and 23rd. Rev. C. Taylor: Two lectures on a lately discovered Document, possibly of the First Century, entitled "The Teaching of the Twelve Apostles," with illustrations from the Talmud. The Friday evening meetings will be resumed on April 17th, when Professor S. P. Langley, of the Alleghany Observatory, Pennsylvania, will give a discourse on Sunlight and the Earth's Atmosphere.

THE LANCET.

LONDON: SATURDAY, APRIL 4, 1885.

THE action which has been taken by the vestry of St. Pancras, and which has led to the resignation of Mr. SHIRLEY MURPHY, brings into special prominence the unsatisfactory position in which medical officers of health are placed with regard to the sanitary authorities whom they serve. It is a fact too well known to require any further proof that in a great many instances sanitary authorities intimate to medical officers of health, either directly or indirectly, that the less they do towards the improvement of their districts, the more secure will be the posts and the emoluments they hold. And, on the other hand, the officer of health who honestly performs his duty, and makes it his first consideration to deal with all matters affecting the health of the public, quite irrespective of the private interests which are involved, often finds that his position is made so disagreeable that he is bound to resign it; or else, when the time of re-election arrives, he is thrown over and a new officer takes his place. Nothing could be more unsatisfactory than such a condition of affairs, and the time has come when all who are interested in the future sanitary welfare of the country should make it known in an unmistakable way that a change is necessary in the direction of placing the medical officer of health on a more secure footing.

When the appointment of medical officers of health became compulsory throughout the country, the Local Government Board issued certain regulations with regard to such of them as held office under their Orders; and it is quite clear, from the wording of the clauses relating to the tenure of office, that the intention of the central authority was that after a certain period of probation the election should be permanent, unless removal from office was sanctioned by the Local Government Board on the application of the authority. Indeed, the only limit to the length of appointment had reference to the first election, which was to be for a period not exceeding five years. But even as regards appointments which are made under the Board's Order, the number in which permanency has been sanctioned is very small; and, as a matter of habit, even those sanitary authorities who desire to make permanent appointments are not allowed to do so. As to those districts in which the authorities do not claim any repayment of the officer's salary from the Parliamentary grant, no guarantee whatever is required as to tenure of office, and officers of health may be appointed and dismissed as often as the authorities choose. The metropolis, owing to its exceptional legislation, is on the same footing, and any officer can be got rid of, either directly or by persecution, as soon as the authority finds that in the proper performance of his duties he is touching individual interests.

For the purposes of the Poor-law Medical Service, it was found necessary to give to the medical practitioners holding office in that service some security that they should not be dismissed without adequate reason; and though it may be that this provision has not always worked satisfactorily, yet it has enabled many officers to perform their duties fearlessly, and with the conviction that there was at least some court to which there was appeal. In the interests of public health, it is necessary that medical officers of health should be placed on a footing, to say the least, not inferior to that of Poor-law medical officers; and strong representations should be made to the Government and to individual members of Parliament with a view of securing some such end. The loss to a sanitary district of a medical officer of health who is fully acquainted with its various needs, who has shown his ability to indicate those needs and to secure their remedy, and who is sacrificed because of his very efficiency, is well-nigh irreparable; for even if his successor be as competent as he, much time must elapse before an in-coming officer can have acquired the local information necessary to the proper performance of his duties. In Mr. SHIRLEY MURPHY's resignation St. Pancras is the principal sufferer; and the mere fact that certain members of the vestry have been allowed so to behave towards that gentleman as to compel his resignation will, it is certain, most seriously affect the future sanitary status of any man who cares hereafter to take upon himself the duties of medical officer of health in that parish. The Parliamentary Secretary to the Local Government Board has borne testimony in the House of Commons to Mr. SHIRLEY MURPHY's conscientious and capable performance of duty; the Mansion House Council on the Dwellings of the People have publicly protested against the treatment he has received; and it is to be hoped that the publicity which has been given to this case, one out of many similar instances, will in the end lead to a change in the relations of medical officers of health to the local authorities, both in the metropolis and elsewhere. If this result be attained, those who have suffered will not have done so in vain.

◆

THE debate on Cholera was resumed at the Royal Medical and Chirurgical Society last Tuesday, and brought to a conclusion, although an attempt was made to have it further adjourned, in order, as one speaker stated, to secure opportunity for Dr. KLEIN to reply. The rules of debate do not, however, admit of a reply except to the opener, and in the opinion of the majority the subject has for the present been sufficiently discussed. Dr. HENEAGE GIBBES denied categorically the interpretation placed by Mr. WATSON CHEYNE upon KOCH's statement that the ileum in acute cases contains comma bacilli in pure culture; for, according to Dr. GIBBES, the small straight bacilli which he finds to predominate in such cases are specifically distinct from the curved microbe. Neither could he confirm the statement that the number of comma bacilli was in proportion to the severity of the case. Dr. HERON, who spoke later in the evening, reverted to the bacillar question, and maintained that no difference of opinion had been elicited as to the fact that KOCH's bacillus had occurred in any other disease but Asiatic cholera; although, as Dr. THIN remarked, an impression had been conveyed that Dr. KLEIN still maintains the contrary. Dr. THEODORE ACLAND asked for information on this point, but, as Dr. GIBBES had left the room and Dr. KLEIN was not present, no reply was forthcoming. But, assuming the truth of his interpretation, Dr. Heron pointed out the great importance of this fact as a means of diagnosis between Asiatic cholera and allied diseases, following in this the opinion long since expressed by Koch, at whose instigation so many sanitary officers and others have been instructed at Berlin in the methods of discriminating the choleraic microbe. Sir Guyer Hunter took occasion to reiterate his conclusion that in the Egypt epidemic the disease was not imported from India, nor did he believe that the Toulon outbreak was imported. In fact, he declared stoutly in favour of the non-contagionist doctrine, which Dr. Cuningham has so persistently upheld. Yet, in the face of such facts as those furnished by Mr. Macnamara in his able speech, and those included in the trenchant criticism lately bestowed on Dr. Cuningham's own reports by the writer of a pamphlet entitled "On the Communicability of Cholera by Human Intercourse"—an author who is in a position to speak with authority,—it does seem astonishing that the non-contagionist doctrine should still receive so much support. Surely there is abundant evidence for regarding cholera as on the same etiological footing as typhoid fever. Mr. Macnamara appears in practice to have found that the most appropriate treatment is just that which Koch finds obnoxious to the bacillus, and is therefore all the more inclined to accept the interpretation of Koch in its most extended significance. Other speakers were less assured that the bacillus stands in causal relation to the disease. Dr. Pye-Smith contributed some weighty remarks upon the nature of the choleraic discharge, which, from experiments made in conjunction with Dr. Brunton, he believes to be due to an outpouring of intestinal secretion by paralysis of mesenteric nerves in connexion with ganglia derived from the solar plexus. As might have been expected, much was said about treatment; and Dr. Johnson's advocacy of elimination by means of mild purgation was attacked by many, including Sir Guyer Hunter, Dr. John Murray, Mr. Macnamara, and Dr. Scriven; although the latter declared that he had found calomel most useful in the early stages. Other statements of Dr. Johnson were combated; but he defended his position with vigour in the short time left to him at the close of the protracted meeting.

Dr. George Peabody, Physician and Pathologist of the New York Hospital, read a paper to the Practitioners' Society on the 6th of March on toxic enteritis caused by corrosive sublimate as a surgical and obstetric application. He adduces from the records of the New York Hospital accounts of eleven cases in which the use of the perchloride as an antiseptic dressing or application was followed by obstinate diarrhœa, which did not yield to the usual remedies, which sometimes ceased on the drug being discontinued, but which in seven instances was followed by frequent bloody discharges, griping, tenesmus, prostration, and death. He was led to search out the facts by reading an article by Dr. Eugen Fraenkel in the February number of Virchow's *Archiv*, whose attention had been drawn to the subject by reading a short communication in the *Centralblatt f. Gynäkologie* by Stadfelt of Copenhagen, in which is reported a fatal case of poisoning in a woman who was treated, after retained placenta had been removed with the hand, by the washing out of the uterus with a solution of corrosive sublimate of the strength of 1 in 1500. Four hundred cubic centimetres of this solution had been injected into the uterus, when sudden collapse occurred, from which she rallied. On the evening of the same day she had diarrhœa and tenesmus, and later, bloody stools, which continued until her death, ten days after. The autopsy showed numerous ulcers of an irregular or circular shape in the large intestine. The mucous membrane generally was congested and the ulcers frequent in the rectum. These appearances of the intestine corresponded closely with what was noticed by Dr. Peabody in several of the autopsies he made of surgical cases where the bichloride had been used, as for irrigating abscess cavities, irrigating wound after amputation of the breast, irrigating a suprahydatid cyst; wiping the peritoneum after laparotomy for fibro-myomata with sponges wet with bichloride solution, 1 to 2000 parts. Fraenkel says he has made autopsies of fourteen cases treated by Schede with bichloride during the last two years and a half, in which toxic enteritis was produced by it. Of these fourteen cases, two, he thinks, were killed by the poison directly. In the others the drug did not seem wholly responsible for the fatal issue. Salivation is exceptional in these cases. Inflammation is always present in the large intestine, but only exceptionally in the smaller. In the large intestine Fraenkel found very extensive superficial ulcerations, sometimes covered with loose masses of epithelium and sometimes by a torn diphtheritic membrane. The lesions of pyæmia in other organs are uniformly absent. Dr. Peabody refers to a publication by Schede of Hamburg on this subject in *Volkmann's Sammlung Klin. Vorträge*, No. 251, and also to one in the same work, No. 250, by W. Thorn, assistant at the Female Clinic in Halle, which is an urgent plea for the total abolition of the corrosive from midwifery and gynæcology, alleging its great inferiority to carbolic acid, and the dangers attending its use. We think it incumbent upon us to give publicity to these publications, as we have lately recorded with much satisfaction the remarkable absence of mortality in the General Lying-in Hospital of York-road, Lambeth, where the patients are douched with solutions of the bichloride twice a day. These, of course, are only vaginal douches. We have been informed that there was, except possibly in one case, an entire absence of any indication of the constitutional action of the poison. It is clear, however, from surgical experience that this solution will have to be used very cautiously, and not less so in obstetric practice. We should be disposed to say that its intra-uterine use is not warranted. There is a growing disposition, except in extreme cases, to trust to vaginal cleansings.

The Government Lunacy Bill is not yet printed, so that it is not possible for us to discuss its provisions in detail. So far as we can judge from the statement made by the Lord Chancellor when introducing it, the measure would seem to be one of those well meant but feeble endeavours to do right which reflect more credit on the hearts than on the heads of their projectors. Of course, it may be that in this instance the head has had more to do with the matter than the heart, and that, in point of fact, it is a concession, with ingenious reservations, made to the urgent cry for reform. We do not attempt to determine in which light the new

Lunacy Bill is to be regarded. One thing, however, is certain; an attempt must be made to improve it by amendments. In some respects this should be easy. For example, the provision by which a person consigned to an asylum is to be visited by a delegate of the Commission within a *month* (!) of his admission must obviously be so modified that the official visit shall be paid within a week as the utmost limit. If the examination and report thus made are to be of any value they must be completed at the earliest practicable date. Imprisonment of a weak-minded though not insane person for a month in an asylum would more than suffice to drive him into madness. Even three or four days of wrongful incarceration would do the utmost mischief in a great majority of instances. If the official representing the Commission, and therefore *supposed* to be impartial, does not visit within one week, it is needless to trouble to send him at all; the alleged lunatic will be quite mad before he comes! We do not complain that the Government has hesitated to abolish the private asylum system altogether with one sweep of the pen; but the Bill, as represented, trusts largely and implicitly to the energy of local reformers for its efficiency, and everything will depend on the way its provisions are carried into effect. We suspend our judgment on the details of the measure until we see it in print.

WE drew attention in our issue of March 7th last to the proceedings of the Metropolitan Asylums Board in connexion with the excessive expenditure at the Homerton Fever Hospital, and especially to the resolution which was passed by that Board to the effect that the result of the inquiry of the subcommittee showed the unfitness of the present medical superintendent for the office he holds. Dr. COLLIE has raised a protest against this resolution, and he naturally expresses surprise that it should have been passed without his having an opportunity of offering to the Board of Managers the explanations which he now tenders. The charges which, in the opinion of the managers, have reference to Dr. COLLIE arrange themselves under four heads. In the first place the general expenditure of the establishment is regarded as excessive. As to this Dr. COLLIE shows clearly that, except in so far as he has advised the carrying out of certain important and necessary improvements, such as alterations in the system of drainage, he is in no way responsible for such expenditure. The general expenditure, he declares, is controlled and directed solely by the hospital committee; and, except on rare occasions, when some special medical questions arise, the estimates are dealt with without so much as his being consulted. Another and a very important charge relates to the amount of stimulants given to patients. On no subject has there probably been a greater divergence of opinion in medical circles than on this question of the administration of alcohol in the case of the acute specific fevers, and therefore the mere citing of the amounts of wine, &c., administered per patient at different hospitals is altogether beside the mark when the point under consideration is the fitness of this or that practitioner efficiently to supervise a large fever hospital. The matter is one for medical judgment, and we are bound to say that Dr. COLLIE who has often expressed his views upon what has by some been regarded as his lavish use of alcohol, bases his practice upon what he rightly believes to be the only proper ground—namely, the welfare of the patient. Indeed, in *support of his method of treatment he gives the mortality* per cent. of admissions during the last twelve years in the Stockwell Fever Hospital, in the London Fever Hospital, and in the Homerton Hospital, and the result is that on a total of patients varying from 1797 in one to 3604 in another of the hospitals, the death-rates have been at Stockwell 21·54, in the London Fever Hospital 16·14, and at Homerton 15·15 per cent.

We are not now, however, concerning ourselves in any way with the question whether Dr. COLLIE's method of treatment is right, or whether sources of error may not have to be eliminated before the figures he quotes can be accepted as proving all he alleges. The point is that he honestly believes he saves life by his alcoholic treatment, and that he is able to quote statistics which he holds are in favour of his confirmed opinion. So long as this is the case it is only right that his medical judgment should be unhindered, and it is clear that on this, as also on the first head, he entirely absolves himself from the charge brought against him. A third point relates to the supply of stimulants to the staff. Some of this has been granted without any order from Dr. COLLIE, and some of it he has "years ago" declined to hold himself responsible for. There has also been some exceptional use of beer on account of the works of drainage which have been carried out. It was naturally desired to keep the men working in an infectious hospital from the neighbouring public-houses, and hence beer, as also lemonade, were provided for them. But even here Dr. COLLIE declares that he never ordered an ounce of the beverages, neither was he concerned with the quantities issued. The remaining item under this heading Dr. COLLIE regards as one coming properly within his jurisdiction. It has relation solely to the sick members of the staff, and, having regard to the heavy nature of the duties they had been called upon to perform, Dr. COLLIE declares that under similar circumstances it would be his duty to act in the same way again. Here again the matter is one essentially for the judgment of the responsible medical head. The last charge is of a different character. Excessive amounts of Beaune wine were delivered to a certain ward early in July last year. Dr. COLLIE admits that it was his duty to have checked this, and that he is properly to be held responsible for what was unquestionably a grave irregularity. But he submits that at the time in question he was engaged on many other matters for the board of managers, that the diet sheet was made up by the *superintendent nurse owing* to the illness of one of the medical officers, and that he is in consequence unable to offer any satisfactory explanation of the circumstance. Clearly Dr. COLLIE has erred here. But surely the past history of his services should afford ample proof that the matter is one of error alone. For a long time past the expenditure of Homerton Hospital has at intervals been considered, the cost of the establishment has been submitted to the managers fortnight by fortnight, and never during the past fourteen years has Dr. COLLIE received a hint, a caution, or a warning that his medical administration was too costly. During his long service he has received numerous proofs of the confidence of the managers in his ability as an administrator. Apart from his general work, he has been called upon to prepare land and floating hospitals against epidemics of small-pox, special recognition of his exceptional services has been made to him, and he has all along been regarded as one of the highest authorities on the subject which he has made his particular study. Should Dr. Collie feel that, in the present attitude of the Managers, he can no longer hold his present post, the metropolis would lose the services of one of the most able physicians who ever set himself to cope with the control of epidemic disease by isolation; and we cannot but express a confident hope that his explanation will be accepted as sufficient, and that he will continue to hold the post for which he is so exceptionally well fitted. A Local Government Board inquiry has been ordered as regards the whole subject, and this will probably clear up all doubt as to where the fault lies.

Annotations.

"*Ne quid nimis.*"

ROYAL COLLEGE OF PHYSICIANS.

The Comitia on the 30th ult. was very largely attended, Sir W. Jenner presiding. The Certificate of Hygiene was awarded to Messrs. Charles Bullock, Charles W. Low, William F. Taylor, and Francis J. Tuohy, this being the first occasion of the newly established examination. A communication was read from the Treasury undertaking to comply with the request of the College to distribute free of cost amongst the medical practitioners of the United Kingdom copies of the revised "Nomenclature of Disease." A vote of thanks to the Treasury for its courtesy and liberality was proposed by Sir Risdon Bennett, seconded by the Senior Censor, Dr. Ogle, and unanimously carried. The President intimated that at the next meeting he should propose that an honorarium be voted to Dr. Ord, the Secretary of the Nomenclature Committee, for his invaluable services. The scale of payment of examiners was submitted and approved. Dr. George Johnson drew attention to the proposed publication in facsimile of the MS. notes of Harvey in the British Museum, and a committee consisting of Drs. Johnson, Sieveking, Stone, Payne, and N. Moore was appointed to report thereon to the College. Sir W. Jenner then delivered an address, in which he reviewed the various subjects that had occurred in connexion with the College during the past year. Amongst these he referred to the Medical Bill, and its withdrawal owing to the determined opposition of the Scotch universities, and stated that the measure had received the support of the College, which was more mindful of the interests of the profession and the public than of its own corporate interest. Since the Bill had not become law, the College had, in conjunction with the College of Surgeons, formed an Examining Board, which had received the sanction of the Medical Council. Objection had been taken to the fees charged for these examinations; but until the scheme was well established, it would not be possible to lower them. The question of a London medical degree was one which might well be entertained in connexion with the new board, and he thought the College might institute an inquiry into the best means for obtaining the power to grant degrees. Many other topics were dealt with, and the address concluded with a review of the careers of those Fellows who had died during the past year—an eloquent tribute, characterised by much discrimination and high-toned feeling. A cordial vote of thanks for his address was passed to Sir William Jenner, who was then re-elected President by a large majority, a certain number of votes being also recorded for Sir W. Gull, Sir H. Pitman, Dr. Owen Rees, Sir A. Clark, Dr. Quain, Dr. Wilks, and Sir Joseph Fayrer.

ENGLISH VITAL STATISTICS IN 1884.

The Registrar-General's Abstract of Marriages, Births, and Deaths, registered in England and Wales during 1884, has just been issued as a Parliamentary Return. The marriages were fewer than those recorded either in 1882 or 1883, and were equal to a rate of 15·1 persons married per 1000 of the estimated population. This marriage-rate was as low as that in 1881, and very slightly above the low rates in 1879 and 1880, when the present depression in the marriage-rate was most marked. In sympathy with the long continued depression of the marriage-rate, the birth-rate is also much depressed, and did not exceed 33·5 per 1000 last year and showed but a slight recovery from the exceptionally low rate in 1883; it was 1·4 below the mean rate in the ten years 1874-83. The deaths registered last year were equal to a rate of 19·6 per 1000, and was almost identical with the rates in the preceding two years, 1882 and 1883, which were 19·6 and 19·5. The mean annual death-rate in the first four years of the current decennium was but 19·4 per 1000, and was no less than 2·0 below the mean rate in the ten years 1871-80, in the latter half of which period a considerable decline in the national death-rate had already set in. The marked decline in the death-rate of the last four years signifies that nearly 213,000 persons in England and Wales survived those four years whose deaths would have been recorded had the death-rate equalled the mean rate that prevailed during the preceding ten years. The natural increase of the population of England and Wales last year by excess of births over deaths was 376,623, and was higher than in any previous year on record, except 1881, when the death-rate was unprecedentedly low. On the other hand, 150,652 English emigrants left the United Kingdom during the year (fewer by 19 per cent. than those in the previous year), whereas the number of immigrants and of returned emigrants is unknown. The net increase to the population of the country cannot therefore be ascertained. From a health point of view the vital statistics of 1884 were eminently satisfactory, and the continued depression in the low marriage-rate, viewed as the reflex of the commercial depression, was to some extent counterbalanced by the decline both of emigration and of pauperism.

ALLEGED DEATH FROM VACCINATION.

On Saturday, March 28th, Dr. Danford Thomas, the coroner for Central Middlesex, held an inquiry into the cause of death of a child named Walker, aged three months. From the evidence it appears that deceased was vaccinated by Mr. Claremont, public vaccinator to the St. Pancras district, on March 5th. At that time it seemed quite healthy. On the 12th—the day being very cold—it was taken for inspection. Two days afterwards the mother called in Mr. Whitefoord of Albany-street, and that gentleman diagnosed "*congestion of the lungs and brain.*" Death took place from convulsions on the 22nd ult. Mr. Whitefoord signed a certificate to the effect that the fatal issue was due to vaccination, blood poisoning, and convulsions. Upon the information laid before him the coroner very wisely determined to hold an inquest. The post-mortem examination was performed by Mr. Pepper, in the presence of the gentleman named above, Mr. Sweeting of the Local Government Board, and other members of the profession. The vaccination marks were perfectly normal, there being not the least trace of ulceration beyond the adherent scabs. The surrounding areolar tissue and the axillary lymphatics showed no trace of suppuration. The internal organs, with the exception of the lungs and brain, were free from disease. There was no sign of acute fatty softening or other result of septic intoxication or infection, no thrombosis or hæmorrhagic infarction. There was no effusion into the joints. The lungs showed acute capillary bronchitis, and patches of collapse consequent on the obstruction to the passage of air from the blocking of the tubes. There was no pneumonic consolidation. The pia mater was infiltrated with puro-lymph; the middle ear was healthy; no evidence of tuberculosis was discovered in any part of the body. On being questioned by the coroner and jury, Mr. Pepper stated that in his opinion vaccination had no other part in causing the death than that for the time being it somewhat depressed the vital powers, and so rendered the tissues more vulnerable; and, further, that the capillary bronchitis and pia-meningitis were in all probability directly due to exposure to cold. With regard to the latter lesion, he deposed that inflammation of the cerebral meninges was not uncommon in young children apart from vaccination or any other discoverable source of local irritation. Mr. Sweeting testified to his having examined the vaccinifer—a perfectly healthy child exhibited in court,—its vaccinifer, and about thirty other children vaccinated from them, and that in only one case had the arm assumed unhealthy action, and that as the result of an attack of measles contracted four days after vaccination. By Mr. Whitefoord's certificate, it would seem that he intended to convey that vaccination had in some way led to septic poisoning, and so to the death of the deceased; but when submitted to interrogation, Mr. Whitefoord had no hesitation in saying that by "blood poisoning" he meant only the ordinary effects of arm-to-arm vaccination, which he considered an undesirable method of procedure. To our minds the public and the profession generally would be led to draw a very different conclusion from the terms of that certificate, and the jury by their verdict recorded their sense of disapproval of Mr. Whitefoord's nomenclature when they found his certificate "misleading and incorrect." We do not think that Mr. Whitefoord can claim to represent the opinion of his professional brethren in considering that the "congestion of the lungs" was due to blood poisoning, and not to exposure to cold, on the grounds that the appetite of the patient was not completely lost, and that there was no difficulty in breathing. The latter statement of fact, however, was directly traversed by the mother of deceased, for she avowed that one reason why she sought medical advice was on account of the difficulty of breathing which Mr. Whitefoord failed to recognise. As regards arm-to-arm vaccination, it is only necessary to add that the Local Government Board have issued instructions that it is preferable to vaccination by ivory points. The wisdom of such instruction seems plain enough. The virus when exposed has a chance of undergoing decomposition, which, although it may attenuate the specific principle, opens up the possibility of introduction of septic matter. Besides, it has been proved by experiment that it is impossible to remove the whole of the virus from the points, as some of it passes into the pores of the ivory. We cannot help expressing our conviction that Mr. Whitefoord should have more carefully weighed the probabilities as to the construction likely to be placed on the wording of his certificate. The cause of vaccination has enough to contend against without its opponents being furnished with phraseology which does not convey a complete representation of facts, and, as in this case it seems, not even a correct statement of opinion.

ATHETOSIS BEFORE AND AFTER HEMIPLEGIA.

THE relations of convulsion to paralysis form one of the most interesting chapters in the pathology of the nervous system. The popular mind sees a wonderful contrast between convulsion and paralysis, and with good reason. Yet there are many considerations which tend to diminish the contrast. The causes which give rise to involuntary movements need only to be intensified in order that paralysis may result. A moderate defect in the nutrition of nervous tissues subserving motor functions may be outwardly expressed as epilepsy, chorea, or some other form of involuntary movement; whilst a more marked defect in the nutrition would be followed by paralysis. It is true that in many instances genuine irritation calls forth some form of tonic or clonic spasm, which may end in paralysis from exhaustion consequent on the excessive irritation. Perhaps the majority of cases of Jacksonian epilepsy which are followed by paresis may be thus explained, though it is highly probable that a condition equivalent to irritation may be set up as the result of a mere loss of nutrition. Paralysis which is not caused too rapidly is generally preceded by some form of spontaneous movement. At a recent meeting of the Société de Médecine et de Chirurgie of Bordeaux, M. Durand related the case of a man aged sixty-nine who was one day seized with severe epistaxis. The next day a tremor exactly similar to that seen in cases of post-hemiplegic athetosis was observed in the left arm and leg; at least so states the report from which we gather this account. There was no loss of consciousness. A day later the convulsions were replaced by hemiplegia. On the following day the movements had returned, and hemianæsthesia was detected in the convulsed members. The further history of the case was not related, and the description given of the movements is inadequate for a proper recognition of their nature; nevertheless the case is an interesting one.

THE MORTALITY OF PIT VILLAGES.

THE report of Dr. Brown, the medical officer of health of the Winlaton Rural District and of the Blaydon and Pyton Union Districts, has been kindly forwarded to us. It should be widely circulated in the district of Newcastle, as throwing much light on the causes of death that obtain still in villages and small communities in the very heart of the district which is associated with all that is effective in engineering and mechanics. If a little of the genius that has been so lavishly spent on the means of locomotion could only be spared for increasing the means of life, or rather abating the causes of death, what great results would accrue. How much healthier the children would be, and how much happier the parents. Life itself would be ever so much more worth living if the diseases by which it is blighted and impoverished from infancy upwards could be curtailed or abolished. If untainted water could be supplied and the house space increased, infantile diarrhœa and typhoid would largely disappear, and the insidiously introduced infection might have some chance of isolation. If the Blaydon Sanitary Authority is disposed to effect these beneficent changes, it need do no more than read Dr. Brown's report and act upon its suggestions. The significance of much of the disease of which he speaks is unmistakable. Twenty-one deaths in a population of 11,800 from summer diarrhœa; 45 deaths, *in the third quarter of the year*, under five years of age, in a total of 77 deaths; 14 deaths from enteric fever at Blackhall Mill; 68 victims to lung disease, being nearly one-fourth of the whole number of deaths, and 60 deaths of infants: from thrush, 8; tabes, 10; meningitis, 12; convulsions, 18; and premature birth, 12—convey to the medical mind conditions of existence which not only kill, but which debilitate and impoverish those who survive. The mortality of the whole district is that of a crowded city rather than that of rural villages. We will not here reproduce Dr. Brown's account of the water-supply and its intimate relation with wells and ashpits and privies. His language is not that of a sensational alarmist, but of an earnest and kindly physician; and we cannot but hope that it will have the attention of his sanitary authority; and let us hope, also, of beneficent ladies of the district, who, with a little pains, might diffuse among the people intelligent ideas of food, fresh air, housekeeping, &c., pending the arrival of that period described by Dr. Brown when the School Board authorities will think it a fundamental part of their duty to instil into the juvenile minds under their care elementary ideas of health and its conditions.

SUCCESSFUL NEPHRECTOMY AND NEPHROTOMY.

A MAN, aged twenty-seven, has just left the Queen's Hospital, Birmingham, in capital health after removal of his greatly enlarged right kidney by Mr. Jordan Lloyd. The patient had suffered periodically from attacks of right nephralgia for nineteen years, and several experienced practitioners had diagnosed renal calculus. On Nov. 18th, 1884, the kidney was exposed through the loin, its substance incised, and its cavity explored with the finger. The kidney was found enlarged, dilated, and pouched, but without stone. Twelve days later the patient had an attack of nephralgia, followed by a kind of pyæmia. The wound at this time had nearly healed. The general health had so far improved that on Feb. 8th Mr. Jordan Lloyd excised the kidney, through a wound made in the old cicatrix. The gland proved to be greatly enlarged, but its substance was thinned and dilated, without stone. The kidney measured eight inches in length, and the pelvis twelve inches in circumference. The patient rallied quickly, made a rapid recovery, and was discharged on March 19th, with a small discharging sinus in his loin, but otherwise, to all appearance, in perfect health. *La Gazzetta degli Ospitali* reports that on March 8th Professor Vincenzo Dafilo performed nephrotomy at the Ospedale degli Incurabili at Naples for suppurative nephrosis. The walls of the cyst, about three-quarters of an inch in thickness, were closely adherent to the lumbar muscles, the peritoneum, and the diaphragm. The edges of the wound in the skin and cyst were united by points of interrupted suture. The cyst, which had previously been evacuated eight times with Potin's aspirator (yielding a pint and three-quarters of purulent liquid each time), was again emptied in the same way on March 8th. The free extremity of the twelfth rib was resected at the same time. The operation was completed under ether in forty minutes, with the strictest Listerian antiseptic precautions. The temperature has not exceeded 38° C., and the patient is making excellent progress towards recovery.

MALE NURSES FOR MEN.

THERE is some reason in a suggestion which has lately come under our notice, that greater facilities than exist at present should be afforded to steady and intelligent men who are willing to devote themselves to nursing the sick of their own sex. That some such nurses are to be found is not denied. Among others, we may mention the male attendants on lunatic patients—men skilled in the management of a special and very trying form of disease; then there are the "watchers," who belong to the Jewish community, and combine the office of a nurse with certain religious functions. Still, the suggestion we have referred to indicates a want in our system of treatment. It would be easy to enumerate cases in which the services of men would be preferable to those of women in a sick room. In old age, for example, when prostatic and vesical troubles are apt to show themselves in men, or at any age for the after-care of operations in the same region, one may, without excessive refinement of feeling, choose that the necessary manipulations should be performed by the male hand when that has by training become endowed with feminine tenderness. It must, of course, be admitted that true delicacy of feeling is quite compatible with every necessary work, and particularly with one so humane as that of attendance on illness; but there seems no reason why an invalid should not be able to satisfy his own wish in the matter. Another and more pressing argument in favour of male nursing is founded on the greater physical strength and endurance of men as compared with women. Many non-professional persons have witnessed the real advantage conferred by muscular strength—in dealing, for example, with paralysed patients. To lift a heavy man bodily is no trifling task even for the strong. In some cases it is frequently necessary; and it seems somewhat unfair to expect that women of exceptional strength should always be available for such an emergency, or that the aid of another woman or a male relative of the invalid should be conveniently near to make up any deficiency, when many men, if trained, could satisfy every requirement single-handed. Some of the general hospitals would, therefore, we think, do well to assist the formation of a nursing staff of men by using for this purpose the means of teaching which their wards so amply afford. Recent experience has proved that if the course of education could be made to include ambulance work, a reserve force of assistants might be formed whose services would be of great value to the military authorities in case of war.

HORSEFLESH AS FOOD IN MANCHESTER.

THE question as to how far the consumption of the flesh of diseased animals may be carried without injury is one which cannot yet be answered with exactness. Probably it never will be. It is obvious notwithstanding that such meat can never be relied upon to furnish the same nutriment as that of a sound and well-fed animal; and again, that so long as the muscular tissues are traversed by the same organic fluids as the seats of disease, especially if the latter be contagious, they cannot be eaten without risk. A partial security is afforded no doubt by bleeding the carcase efficiently, by using as food only the muscular tissues, and by thorough cooking. None of these, however, can do more than mitigate the probable ill-effects of such haphazard feeding, and the danger thus incurred is proportionately enhanced by the fact that many of the poor upon whom such fare is apt to be foisted content themselves with eating the liver and other viscera, which are particularly apt to suffer from infectious processes within the body. These considerations will help us to understand what is, or at least may be, implied in a statement recently published that horseflesh is being sold in large quantities to the poorer inhabitants of Manchester, under the name of beefsteak, and, further, that many of the slaughtered horses were believed to be diseased. The Local Government Board have properly taken the matter in hand, and will, we hope, succeed in excluding from the market of a prosperous English city a form of food which even in its healthy state is not looked upon with favour as a staple of our national produce.

ALBUMINURIA IN CATS.

THERE frequently exists in the kidney of the cat an enormous accumulation of fat in the cells of the parenchyma. The question has been debated whether this fatty degeneration is pathological or physiological. M. Mathis believes the condition to be abnormal, though of frequent occurrence in cats. The disease is of a different order from that of ordinary Bright's disease; it is not the result of an inflammation, but is due to excessive storing up of the fat—a function which appears to be normal for the kidney of the cat, just as the subcutaneous and subperitoneal tissues are the usual magazines for the storage of fat in other animals. Excessive accumulation in the kidney leads to interference with the function of secreting or excreting urea, and it diminishes the power of taking up the albumen thrown out from the blood in Bowman's capsule. The result appears to be the same as in ordinary Bright's disease, "if we except," says M. Mathis, "the disorders due to increased blood-pressure." A want of docility, with capricious temper, is believed to be the chief clinical symptoms of the disease in cats, and, according to our author, albuminuria is always found under these circumstances. An account of this steatosis of the kidney may be read in the *Lyon Médical* of March 15th.

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.

THE Sixteenth Annual Report of this Hospital shows that it is what its name implies, a National one. Of the 6163 patients who have been received into the hospital, about half have come from London and Middlesex. The other half have come from nearly all the counties of England, from Wales, from Ireland Scotland, and the Channel Islands. During the last year no less than 608 patients have been under treatment. But new blocks of buildings, chiefly at the expense of an anonymous friend, are to be opened in the present year, and another block of buildings, to commemorate the generosity of the late Mr. John Jones, is in course of erection. In view of the great importance of the work of the hospital and its imminent extension, it is highly important that the staff of local physicians should be increased. We made this suggestion in a former year, and we make it still more urgently now. It cannot be better carried out than by appointing Dr. Whitehead and Dr. James M. Williamson, who are already Honorary Surgeons, to Physicianships. It is no secret that Dr. Williamson has applied to the board of management to be transferred from the surgical to the medical staff. He states that surgically there is no demand for his services in the hospital, while medically there is a large field for them. His connexion with the hospital, first as resident physician, and then as surgeon, dates as far back as 1873. We should regard his appointment and that of Dr. Whitehead to the Physicianship as not only just to them, but as likely to be advantageous to the hospital. The case of phthisical patients is one demanding much care and time, and these cannot be given with the present staff.

SANITATION AT LEEDS.

THE sanitary supervision of so vast a town as Leeds presents unusual difficulties. A rapidly increasing population, estimated at 327,324, is spread over 22,974 acres of hilly ground, which it has been found necessary to divide into thirteen sanitary districts. A special sanitary inspector watches over each district, and these thirteen inspectors contrived in the course of twelve months to visit 17,011 houses. Considering that 6746 of these houses required sanitary improvement, it will be seen that the inspectors have been greatly overworked. Some of the cases were particularly instructive and significant. Thus, of 3943 houses with defective drainage, zymotic disease occurred in 323 before the evil could be remedied. In one house, to all appearance perfectly drained, there had been case after case of scarlet fever; ultimately it was found that the soil-pipe leaked. In another house, where diphtheria had occurred, a hole was discovered just below the trap of a drain; and this was especially remarkable, as the tenant had recently removed into this house on account of having lost her husband from blood-poisoning due to the defective drainage of her previous dwelling. In the northern district, the family of a small provision shop keeper were attacked by diphtheria. There were four cases in all; the mother and a child died, and the business was almost ruined. Dr. G. Goldie, the medical officer of the borough, has very properly published a coloured illustration of the drains of this house. In four different places the earthenware pipes passing under the house had been chipped; but in order that a two-foot run of piping might not be lost the broken side had been turned upwards. In this way leakage of water might be avoided, but sewer gas could freely escape into the house. Fortunately such trifling with human life could not now be repeated in Leeds. In June, 1878, the present building bye-laws came into force. According to these regulations, all drains must if practicable be carried outside the houses. When this is not possible, they must be laid in concrete and cemented. These works must further be tested and examined by the municipal officers, who insist on their being truly and properly laid, trapped, and ventilated. But if the bye-laws offer some guarantee for new houses, the old houses can only be remedied by the energy of the sanitary inspectors who, we reiterate, are much overworked.

TABETIC LARYNGEAL CRISES.

AT the last meeting of the Medical Society, Dr. W. M. Ord showed a patient the subject of tabes dorsalis, and Dr. F. Semon demonstrated the presence of incomplete bilateral paralysis of the abductors of the vocal cords in this patient. It appears that the stenosis of the glottis has developed and steadily increased during the past three months, whilst the patient has been under observation. The patient at first did not admit that he had suffered in any way from symptoms referable to the larynx; but later on, however, he experienced severe attacks of choking, which at times seemed to call for tracheotomy. Some authorities regard the laryngeal disturbance as being due to a primary contracture of the muscles of the glottis, but the case in question would seem to lend support to Dr. Semon's view of a slowly advancing paralysis of the openers of the glottis. Dr. Ord is in the habit of examining laryngoscopically all cases of nervous disease, and especially of tabes dorsalis, and there can be no doubt of the value of a systematic examination of such cases. For a history of laryngeal trouble may not be obtained, indeed no laryngeal disturbance need ever have occurred, and yet the laryngeal muscles may be obviously affected.

VEGETABLE FOOD FOR CHILDREN.

MR. SAMUEL MORLEY, with his usual public spirit, has been trying to help the cause of temperance and of thrift by a side-stroke in the direction of dietetics. At a vegetarian dinner given by him on Saturday to the villagers of Leigh, he advanced several reasons why this form of food should be more generally appreciated than it is. He referred to a statement that thorough-going vegetarians are usually total abstainers, advised that children should be largely fed on vegetable fare, and advocated the more extensive cultivation of herbs and fruits as being an industry available for very many of the labouring classes, and less tried by competition than that of cereals. Much might be said on each of these heads. Probably the strictest vegetarians are non-drinkers; but this rule is of course not absolute, and temperance, where it prevails, is no doubt partly a virtue of necessity or of inclination, or a principle, and does not arise out of abstinence from meat. In illustration, one might profitably compare the sober and herbivorous peoples of the tropics and subtropic zone with the largely, though not wholly, grain-eating inhabitants of Northern Scotland, whose sobriety is certainly not above question. The most valuable suggestion, however, in this well-timed address is, it seems to us, that which applies to the food of children. The body of the child consists in great measure of fluid and fatty components, and in a comparatively moderate degree of the active muscular tissues. Its income of nourishment, again, goes rather more to the building up of its constituents than to the supply of their functional expenditure. The more inert materials, such as those of bread, are consequently in request for the laying on of substance; the more energising, as those of meat, find proportionally less occupation. We are not vegetarians, and we think Mr. Morley is not strictly such; but we probably agree in this, that for some persons, and especially children, much can be done in feeding with little meat. It is to be noted, also, that a child's food must be abundant in order to fulfil its purpose. How much more easily he may have plenty to eat of vegetable than of mixed or meat diet in the poorer ranks of our countrymen is too obvious to need remark.

THE HEALTH OF OUR TROOPS IN THE SOUDAN.

So far as we have information on the subject, the health of the troops employed in the Soudan has been remarkably good, and the arrangements made by the medical staff for the prevention, so far as possible, of disease, for its treatment when it occurs, and for affording aid to the wounded, have been most successful; indeed, they are described by the special correspondents as "admirable." But we must not lose sight of the fact that a period is now coming on when the resources of the medical service will be very severely tested. The enforced inaction of the troops during the hot season must undoubtedly prove very injurious; and the effects of solar influence on the men who must necessarily be exposed to it cannot fail to tell on the sick-list. This is indeed already beginning to be manifest at Suakim, where during the late operations several cases of sunstroke occurred. We may look for a somewhat heavy list of such cases, and of heat-fever, dysentery, and possibly cholera. A number of cases of enteric fever are already stated to have been admitted to hospital, and there seems too good reason to believe that they will increase as the season advances. It is satisfactory to know that every provision has been made which foresight could dictate; that there is abundance of medical comforts at hand; that adequate arrangements have been made for the careful nursing of the sick; that an ample supply of ice is to be had as required, and that the means of transport in hospital ships fitted up with every appliance for the treatment of the patients and the efficiency of the medical service have been provided on a very liberal scale. We have not the least doubt that everything will be done by the heads of the medical service which practical experience and scientific knowledge can suggest, but we cannot help feeling anxious about the health of the troops during the coming hot season.

SALIVARY CALCULUS IN A MEDICAL MAN.

DR. DE RATO Y ROCES describes in the *Revista Asturiana de Ciencias Médicas* his own case of salivary calculus. When a child the sublingual glands were indurated and painful; afterwards that on the right side disappeared, but the left gland continued to cause trouble, the pain being felt in Wharton's duct, and there being increased secretion of viscid saliva. These symptoms, however, disappeared for a time. For several years, especially during the later months, pain and inflammation have returned, sometimes extending to the right side. After the acute symptoms have subsided a permanent induration has always remained. Last December Dr. de Rato suffered from a more severe attack of this kind than usual, accompanied by repeated rigors, followed by severe pain and febrile disturbance. Afterwards the inflammation extended, and glossitis and amygdalitis prevented speech and the ingestion of food; then came a copious secretion of viscid saliva. By the fifth day, when the inflammation had to some extent subsided, a probe passed into Wharton's duct detected a calculus, which was extracted by forceps the following day. It was of the shape of a date stone, weighed 540 milligrammes (8·37 gr.), and of the hardness of chalk. Externally it was of a dirty white colour with reddish spots, and internally it was white. Since the extraction of the calculus the induration remains, and Dr. de Rato believes there are also small calculi in the duct.

BIRMINGHAM MEDICAL INSTITUTE.

DR. THOMAS UNDERHILL, J.P., presided at the annual meeting of the Birmingham Medical Institute on the 26th ult. The number of members is now 204, and during the past year no less than 597 books have been added to the library, which now consists of 9274 volumes. The annual income is not yet quite equal to the expenditure, but as the building and library are free from debt, the endowment unencumbered, and the number of members steadily on the increase, a growing feeling of confidence pervaded the meeting. Special votes of thanks were passed to the president, the honorary librarians and secretaries, and very important additions made to the committee by the election upon it of Mr. T. F. Chavasse, Mr. Jordan Lloyd, and Mr. Bennett May. One special feature of the Birmingham Medical Institute is that no ballot or other form of election is required to place a registered medical practitioner on the roll of members. The only requisite condition is that he undertake to observe the regulations, and be recommended by six members of the institute, of whom three shall be members of the managing committee. When this very open method was substituted for the ballot previously in force, it was feared by some that undesirable results might ensue; but in practice it has been found that the six signatures required to constitute membership afford all requisite guarantees. For the ensuing year, Mr. Sampson Gamgee was elected president of the institute, and Dr. Rickards and Mr. John Greene vice-presidents. The honorary librarians, Mr. Lloyd Owen and Dr. Saundby, and the honorary secretaries, Mr. W. G. Archer and Mr. Joseph Hunt, were re-elected.

PHARMACY IN BUEÑOS AYRES.

A REPORT has been made by Señor Puiggari to the National Department of Hygiene of the Argentine Republic concerning the state of pharmacy in Buenos Ayres. By means of a legalised system of granting royalties for pharmacies to non-resident proprietors, and by the permission given to medical students of whatever standing to take the title of pharmacist, a number of those establishments at present in the city are practically in the hands of very incompetent persons. In many of them Señor Puiggari found no measures, and in some where such articles existed the person in charge was incompetent to make use of them. The same remarks also apply to reagents. The examination of the drugs, too, pointed to lamentable ignorance or carelessness on the part of many of the compounders. Taking a simple and cheap substance, acid. sulph. dil., which, according to the Codex, should contain 10 per cent. of sulphuric acid, the proportions in a number of samples taken varied between 5 and 23 per cent. Again, liquor arsenicalis, which should contain 1 per cent. of arsenious acid, was found to vary from ·06 to 1·57 per cent. Coming now to an expensive drug, opium, samples which ought to have contained 10, or at most to have varied from 8 to 12, centigrammes of morphia, actually varied from 8 milligrammes to 18 centigrammes, those containing a serious deficiency being much the most numerous. In order to remedy this condition of things Señor Puiggari recommends the abolition of the royalty system, the separation of the faculties of medicine and pharmacy, and that no one should be granted a licence for a pharmacy without the production of his diplomas and other certificates. He points out, also, the extreme facility with which the pharmaeutical diploma is granted in the Medical Faculty of Cordova. The President, having considered this report, tates that it is impossible to veto the royalty system, but orders that the names of all pharmacies of that kind be published twice a year, so that the public may have the means of judging whether an establishment is or is not under competent management.

A COUNTY COURT JUDGE ON THE REMUNERATION OF MEDICAL MEN.

AT the Framlingham County Court lately, before his Honour, Judge Sir Francis Roxburgh, Q.C., Mr. Alexander Harkness, Surgeon, Debenham, sued Mr. Oscar W. Roberts, of the Club, Malvern, for attendance on Mrs. Roberts. The harges were, roughly, at the rate of *7s. 6d.* per visit and *2s. 6d.* for medicine. The visits often occupied from three quarters of an hour to an hour. The distance from the patient's house was two miles, and the defendant was in good circumstances. In spite of some medical evidence on he defendant's side, alleging the excessiveness of the fees, he judge allowed them, and remarked that he did not know a class of men who were paid worse than doctors in the country. He considered the charges were quite reasonable. We refer to this judgment with the more pleasure that it is only one of several recent decisions by county court judges n which the charges of medical men have been upheld. Medical men are, perhaps, a little too slow to assert their egal claims against ungrateful patients.

HOSPITAL SATURDAY FUND WEEKLY CONTRIBUTIONS.

AMONGST various papers sent us by the Hospital Saturday Fund is a sheet which may be used for *weekly* contributions n every week from March 21st to September 5th, the day of the collection. We have always felt that this was the direction in which the Fund can, and ought to, be developed; and we heartily rejoice to commend it to the favourable notice of foremen and others in a position to promote the Saturday collection, which has certainly never reached a figure worthy of the working classes of the metropolis.

THE AMERICAN MISSION IN SYRIA.

WE have been favoured with the statistics of the American Presbyterian Mission in Syria, including the medical work at St. John's Hospital. The physicians of the Medical Department of the Syrian Protestant College are appointed by the Order of St. John in Berlin as the medical attendants of the "Johanniter Hospital" in Beirut. This charity is supported by the Order of St. John, and served also by the Deaconesses of Kaiserswerth. In 1884 there were 571 in-door patients and 7489 treated in the Polyclinique. No part of the work of the mission does more to justify the eulogy of Lord Beaconsfield—"those sublime men, the American missionaries"—than the medical and surgical part.

THE POISONS BILL.

THE new Poisons Bill, recently introduced into the House of Lords, appears to have excited general dissatisfaction. At a special meeting of the Chemists and Druggists' Association, held at Birmingham last week, and attended by representatives of 4000 chemists, the measure was strongly opposed, as being inimical to the interests of those most intimately concerned. A strongly-worded resolution was carried by acclamation pledging the meeting and the Association to oppose the Bill by all constitutional means, and a special fund was opened for the furtherance of this object. It is stated officially that the Privy Council Office have had the Bill under discussion for some considerable time, and that the schedule has been the subject of prolonged deliberation. It is to be regretted that greater success has not attended these efforts.

THE ROYAL NATIONAL LIFEBOAT INSTITUTION.

IF medicine in its ancient and more homely sphere restrains and seeks to foil the efforts of disease, it cannot in its wider and public application remain unsympathetic towards all other motives and means by which its charge of human life is profited or saved. There are certain points in which the spirit of the National Lifeboat Association is in striking concord with the genius of our own profession. Each has to recognise and contend with an unseen extra-human influence of storm or illness, to read and forecast its peculiar symbolism, to guide a system of preventive skill designed to save life, and to heal or to rescue that life in accordance with laws of a written science. Both meet on common ground when measures of resuscitation must be used in order to complete the work of deliverance from the power of the sea. As medical men, therefore, we are gratified to learn that the sister service of recovery continues her work with unabated vigour, and we do not doubt that every member of our faculty will render her that help which need and opportunity may direct.

THE SICK AND WOUNDED AT SUAKIM.

OUR special correspondent at Suakim, in a telegram dated March 27th, states that the wounded have been removed to the hospital ship *Ganges*: the beds are all occupied but three; no deaths had occurred on board. Captain Dalrymple received a gunshot wound over the clavicle, through the spine of the scapula. The splinters of bone and the ball were removed, and he is doing well. Lieutenant the Hon. A. D. Charteris received a spear wound of the palm of the hand. The hæmorrhage was stopped without difficulty, and his condition is favourable. Surgeon Duigan, R.N., had a bullet wound through the scapula and forearm. He is progressing very satisfactorily towards recovery.

POISONING BY ILLUMINATING GAS.

DR. BIEFEL and Dr. Poleck have recently discussed in the *Zeitschrift für Biologie* the question of the relative fatal effects of charcoal fumes and of illuminating gas, it being asserted that in the former case ·19 per cent. in the air of CO destroys human life in thirty-five minutes, while a limit of 1 per cent. is exceeded in the latter case before a similar result ensues. This is attributed to the presence of oxygen in the gas; but Dr. Wagner has disputed these conclusions on the ground that the experiments were not conducted in a satisfactory manner. He agrees, however, with the statement that a mixture of gas and air possessing fatal properties is necessarily in an explosive condition.

THE PARASITIC NATURE OF MELANOSIS.

A CONCLUSION which will generally be regarded as somewhat extraordinary has recently been arrived at by M. Bard, who believes that a clinical and pathological study of melanosis and certain melanotic tumours is sufficient to prove that these morbid processes and conditions are the result of the action of a parasitic organism. This organism he believes to be no other than the black granules themselves. True, he argues, these granules (and may we add crystalline forms?) do not approximate in character to the majority of known micro-organisms, though he considers that they somewhat resemble the micrococci of actinomycosis.

expenditure. The more inert materials, such as those of bread, are consequently in request for the laying on of substance; the more energising, as those of meat, find proportionally less occupation. We are not vegetarians, and we think Mr. Morley is not strictly such; but we probably agree in this, that for some persons, and especially children, much can be done in feeding with little meat. It is to be noted, also, that a child's food must be abundant in order to fulfil its purpose. How much more easily he may have plenty to eat of vegetable than of mixed or meat diet in the poorer ranks of our countrymen is too obvious to need remark.

THE HEALTH OF OUR TROOPS IN THE SOUDAN.

So far as we have information on the subject, the health of the troops employed in the Soudan has been remarkably good, and the arrangements made by the medical staff for the prevention, so far as possible, of disease, for its treatment when it occurs, and for affording aid to the wounded, have been most successful; indeed, they are described by the special correspondents as "admirable." But we must not lose sight of the fact that a period is now coming on when the resources of the medical service will be very severely tested. The enforced inaction of the troops during the hot season must undoubtedly prove very injurious; and the effects of solar influence on the men who must necessarily be exposed to it cannot fail to tell on the sick-list. He points out, also, the extreme facility with which the pharmaceutical diploma is granted in the Medical Faculty of Cordova. The President, having considered this report, states that it is impossible to veto the royalty system, but orders that the names of all pharmacies of that kind be published twice a year, so that the public may have the means of judging whether an establishment is or is not under competent management.

A COUNTY COURT JUDGE ON THE REMUNERATION OF MEDICAL MEN.

AT the Framlingham County Court lately, before his Honour, Judge Sir Francis Roxburgh, Q.C., Mr. Alexander Harkness, Surgeon, Debenham, sued Mr. Oscar W. Roberts, of the Club, Malvern, for attendance on Mrs. Roberts. The charges were, roughly, at the rate of 7*s.* 6*d.* per visit and 2*s.* 6*d.* for medicine. The visits often occupied from three quarters of an hour to an hour. The distance from the patient's house was two miles, and the defendant was in good circumstances. In spite of some medical evidence on the defendant's side, alleging the excessiveness of the fees, the judge allowed them, and remarked that he did not know a class of men who were paid worse than doctors in the country. He considered the charges were quite reasonable. We refer to this judgment with the more pleasure that it is only one of several recent decisions by county court judges in which the charges of medical men have been upheld. Medical men are, perhaps, a little too slow to assert their legal claims against ungrateful patients.

HOSPITAL SATURDAY FUND WEEKLY CONTRIBUTIONS.

AMONGST various papers sent us by the Hospital Saturday Fund is a sheet which may be used for *weekly* contributions in every week from March 21st to September 5th, the day of the collection. We have always felt that this was the direction in which the Fund can, and ought to, be developed; and we heartily rejoice to commend it to the favourable notice of foremen and others in a position to promote the Saturday collection, which has certainly never reached a figure worthy of the working classes of the metropolis.

THE AMERICAN MISSION IN SYRIA.

WE have been favoured with the statistics of the American Presbyterian Mission in Syria, including the medical work at St. John's Hospital. The physicians of the Medical Department of the Syrian Protestant College are appointed by the Order of St. John in Berlin as the medical attendants of the "Johanniter Hospital" in Beirut. This charity is supported by the Order of St. John, and served also by the Deaconesses of Kaiserswerth. In 1884 there were 571 in-door patients and 7489 treated in the Polyclinique. No part of the work of the mission does more to justify the eulogy of Lord Beaconsfield—"those sublime men, the American missionaries"—than the medical and surgical part.

THE POISONS BILL.

THE new Poisons Bill, recently introduced into the House of Lords, appears to have excited general dissatisfaction. At a *special* meeting of the Chemists and Druggists' Association, held at Birmingham last week, and attended by representatives of 4000 chemists, the measure was strongly opposed, as being inimical to the interests of those most intimately concerned. A strongly-worded resolution was carried by acclamation pledging the meeting and the Association to oppose the Bill by all constitutional means, and a special fund was opened for the furtherance of this object. It is stated officially that the Privy Council Office have had the Bill under discussion for some considerable time, and that the schedule has been the subject of prolonged deliberation. It is to be regretted that greater success has not attended these efforts.

THE ROYAL NATIONAL LIFEBOAT INSTITUTION.

IF medicine in its ancient and more homely sphere restrains and seeks to foil the efforts of disease, it cannot in its wider and public application remain unsympathetic towards all other motives and means by which its charge of human life is profited or saved. There are certain points in which the spirit of the National Lifeboat Association is in striking concord with the genius of our own profession. Each has to recognise and contend with an unseen extra-human influence of storm or illness, to read and forecast its peculiar symbolism, to guide a system of preventive skill designed to save life, and to heal or to rescue that life in accordance with laws of a written science. Both meet on common ground when measures of resuscitation must be used in order to complete the work of deliverance from the power of the sea. As medical men, therefore, we are gratified to learn that the sister service of recovery continues her work with unabated vigour, and we do not doubt that every member of our faculty will render her that help which need and opportunity may direct.

THE SICK AND WOUNDED AT SUAKIM.

OUR special correspondent at Suakim, in a telegram dated March 27th, states that the wounded have been removed to the hospital ship *Ganges*; the beds are all occupied but three; no deaths had occurred on board. Captain Dalrymple received a gunshot wound over the clavicle, through the spine of the scapula. The splinters of bone and the ball were removed, and he is doing well. Lieutenant the Hon. A. D. Charteris received a spear wound of the palm of the hand. The hæmorrhage was stopped without difficulty, and his condition is favourable. Surgeon Duigan, R.N., had a bullet wound through the scapula and forearm. He is progressing very satisfactorily towards recovery.

POISONING BY ILLUMINATING GAS.

DR. BIEFEL and Dr. Poleck have recently discussed in the *Zeitschrift für Biologie* the question of the relative fatal effects of charcoal fumes and of illuminating gas, it being asserted that in the former case ·19 per cent. in the air of CO destroys human life in thirty-five minutes, while a limit of 1 *per cent.* is exceeded in the latter case before a similar result ensues. This is attributed to the presence of oxygen in the gas; but Dr. Wagner has disputed these conclusions on the ground that the experiments were not conducted in a satisfactory manner. He agrees, however, with the statement that a mixture of gas and air possessing fatal properties is necessarily in an explosive condition.

THE PARASITIC NATURE OF MELANOSIS.

A CONCLUSION which will generally be regarded as somewhat extraordinary has recently been arrived at by M. Bard, who believes that a clinical and pathological study of melanosis and certain melanotic tumours is sufficient to prove that these morbid processes and conditions are the result of the action of a parasitic organism. This organism he believes to be no other than the black granules themselves. True, he argues, these granules (and may we add crystalline forms?) do not approximate in character to the majority of known micro-organisms, though he considers that they somewhat resemble the micrococci of actinomycosis.

COCAINE FOR THE SOUDAN.

We are *glad to hear that the National Aid Society has arranged to send a supply of cocaine for the soldiers and sailors in Egypt and the Soudan. This is a thoughtful and commendable step, the costly nature of this drug rendering* it otherwise only too likely to be conspicuous by its absence. The Society, to the Princess of Wales's Branch of which the Queen has *forwarded a donation of £50* and *a case* of tobacco, is also sending out nurses, cooking sisters, and a variety of comforts and amusements for the troops.

From the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of February, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies exhibited, on the whole, a slight increase in the amount of organic matter, the proportion being greater in the water of the Southwark and Grand Junction, and least in that of the Lambeth and Chelsea Companies. The water supplied from the Lea by the New River and East London Companies contained slightly less organic matter than the previous month's samples, the New River Company's supply being in this respect far superior to any of the Thames waters, whilst the East London Company's supply ranked with the best of the Thames waters. All the samples were clear and bright.

From the reply of the Local Government Board to a memorial recently forwarded by the North-Western Association of Medical Officers of Health on the subject of revaccination, it appears that the Board are not prepared to propose for the sanction of Parliament an increase in the rate of payment for revaccination relatively to the rate *which boards of guardians may appoint for primary vaccination*; nor are they prepared to furnish to all medical practitioners lymph for the revaccination of the several *persons whom these practitioners may think proper to* vaccinate. With regard to this latter point, the Board are satisfied that such revaccinations as are performed in any *locality with lymph supplied at the public expense* ought to be done as part of the system of public vaccination appointed for the locality.

The Local Government Board have transmitted to the Isle of Thanet Sanitary Authority the report of Dr. Davies, their medical inspector, on the *sanitary condition* of that extensive district. It appears from this report that the water-supplies of the villages of Minster, Monkton, and Sarre are derived from shallow wells, many of which the inspector says are liable to pollution. The Local Government Board therefore urge upon the authority the necessity of providing a public water-supply for the villages mentioned under the powers of the Public Health Act.

Mr. Adam Sedgwick has in preparation a new book, to be entitled "The Elements of Animal Biology," which is intended to serve as an introduction to the study of Animal Morphology and Physiology. Messrs. Swan, Sonnenschein, and Co. are to be the publishers.

Surgeon-Major Oliver Codrington has been temporarily appointed Assistant Professor of Military Surgery at Netley, in the vacancy occasioned by the departure of Surgeon-Major Tobin for Suakim.

The *Przeglad* of Lemberg announces that cholera has broken out in the Crimea, and states that the Russian authorities are endeavouring to suppress all publication of details.

The Eastbourne Board of Guardians have resolved to adopt the suggestion which we mentioned some weeks ago as being advocated by Lady John Manners, and intend providing a mincing machine at the union, for the benefit of the inmates who are old and toothless.

The International Conference on the Prevention of Cholera in Europe has again been postponed. Signor Mancini has now telegraphed to the various European Governments requesting that the several delegates may be instructed to assemble at Rome on May 1st.

The American medical journals announce the death, on March 10th, of Dr. Ellerslie Wallace, Emeritus Professor of Obstetrics and Diseases of Women and Children in Jefferson Medical College, Philadelphia—the chair previously occupied by Dr. C. D. Meigs.

PHOTOGRAPHY AND MEDICAL JURISPRUDENCE.

THE DETERMINATION OF PERSONAL IDENTITY.

BY WILLIAM MATTHEWS, BRISTOL.

In all books dealing methodically with the topic of medical jurisprudence, attention is directed to that division of the subject which treats of legal identification and its related particulars. The rules and usages by which the procedure is governed are primitive, but of long antiquity. Whether before the accredited officer of the Crown, the county coroner, or before the courts of criminal law, the corporal presence of the individual touching whom the inquiry is on foot is an indispensable preliminary. "If the body be not found, the coroner cannot sit," says Blackstone. "An inspection of the body is the essence of the inquiry," observes Dr. Taylor in the "Principles of Medical Jurisprudence." Upon occasion in the courts of civil procedure also the question of identity becomes the essential feature of the investigation. It is the real issue submitted to the adjudicators. "In such instances," says Dr. Beck, "the whole evidence turns on the question of identity." Stature, temperament, marks upon the person, colour of the hair, colour of the eyes, general resemblances, these have, heretofore, been the ordinary elements of the physiological sort upon which a conclusion has been based.

When and where photographic portraiture was first introduced to the notice of the courts does not clearly appear. Certainly, it has not been received with undeviating reliance; for the photographic presentment in many instances differs very materially to the eye from the personal reality. Witnesses, upon their oath, have sometimes been requested to pronounce upon resemblances from which, under ordinary conditions, they would have shrunk in bewildered uncertainty. Yet when considered from the stand-points (1) of their perfect accuracy of delineation, (2) of their minutely-true reproduction of the proportionate areas occupied by the several features, and (3) of the apparent permanence, in adult life, of those proportionate areas, there would certainly appear to be no inscrutable reason why photographs might not be subjected to tests of a severely scientific nature.

There are three or four indispensable conditions to be accepted by scientists, preliminary to such a consummation. 1. A due recognition of the permanence of the essential particulars of a given face. 2. Of the greater or less divergence of all other faces whatsoever from the permanent particulars of the face in question. 3. The requisite reliability of a unit of admeasurement that shall, similarly, be (*a*) permanent in a given face; (*b*) discrepant, more or less, in all other faces. 4. The accredited presence of a sufficiently undeviating horizontal plane, to afford an available zero or datum line.

Now, in order to sustain the proposition that a given adult face is permanent in its chief particulars, it needs be the obvious reflection—(1) that when a man stops growing the bones of his face stop growing at the same time, as all the rest; and (2) that when the bones of the face cease growing, the several features thenceforward retain in permanence their original *locus in quo*. It should go without saying that the requisite unit of the admeasurement must necessarily be sought in the face itself; for by this expedient the varying magnitudes of photographic portraits are effectually provided for. Hence the adaptability of the coloured circle of the eye for the desired purpose—(1) It is well-defined at its exterior circumference; (2) it is a permanent quantity in a given individual; and (3) its dimensions so materially differ in different persons, that of itself it is an important factor of diversity between photographs that are inherently discrepant. Granted, then, the requisite permanence of the facial perpendicular, and the requisite permanence of the unit of the admeasurement (the diameter of the iris at its exterior rim), it remains but to consider the limitless amplification of the facial diversity. It has been long an accepted hypothesis that the dimensions of an ideally perfect face should consist of certain duplicate and triplicate repetitions of its own elements; yet, nevertheless, that all actual faces are, to a greater or less extent, departures from the given ideal. In strict conformity with this hypothesis it may be pointed out that the endlessly numerous permutations which are everywhere consequent upon the presence of even a few factors of diversity is a matter quite amenable to arithmetic proof. This principle of permutation finds its always familiar illustrations in the "ringing of changes" upon an octave of bells, in the casting of dice, and in the myriads of differing verbal forms that a few vocal articulations have afforded to all the nations of the earth.

In conclusion, the general and special data which have been here set forth appeal in the first instance to the common apprehension of men of intelligence; and, secondarily, to the tests and investigations of experts. As the result of such tests and investigations, it is now confidently maintained that the data and conditions enumerated are trustworthy, and open to proof. The photographic portraits of various public personages, taken after intervals of twenty or more years, and suitably enlarged, have been found to correspond very minutely in admeasurement, whilst in the meanwhile great external change has been going forward in their countenance. On the other hand, a comparison of the portraits of any two distinct individuals, tested under the same rigid conditions, fully justifies the statement that, in such cases, varied and palpable discrepancies will inevitably become manifest.

The physiological facts having been accepted, the formularies of procedure may suitably engage attention. To those to whom the topic is new, an explicit statement of details might prove the more convenient; but summarily and technically, those particulars may be dealt with as follows:—1. Upon a photograph of enlarged magnitude let a right line be drawn from centre to centre of each pupil. 2. From the given centres describe arcs intersecting each other, above and below the right line, of a radius as the distance between the centres. 3. From the points where the arcs cut each other produce the perpendicular. This will, necessarily, be the true facial perpendicular, whatever may be the pose of the sitter. 4. Lay off a parallel on either side of the perpendicular at the distance of the given centres. 5. Lay off a series of parallels, above and below the line of the pupils, and let their measured distance apart be that of *precisely the diameter of the iris*. 6. Let each parallel extend over the right-hand margin of the portrait, and be numbered consecutively. The given line of the pupils being a naught or zero, let the other numbers proceed from it, upward and downward. 7. Reproduce these details upon the second portrait, and thereupon proceed to make the necessary comparison of particulars.

With the aid of the appliance known as the "identiscope," the required comparison can be effected under conditions the most favourable for careful inspection. Reproduced upon lantern-slides, conjoined by the agency of the zero-points, the compared portraits may be projected in combination, upon a scale of magnitude that would cause the most minute discrepancies to stand revealed, in any reputed instance of spurious or assumed identity.

UNIVERSITY OF ABERDEEN.—The Keith medal, instituted in commemoration of the late Dr. Keith, has been awarded to Mr. George Findlay. Clinical and general surgery form the subjects of examination.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

The Sanitary State of Alnwick, by Mr. JOHN SPEAR.[1]—The attention of the Local Government Board has for some years past been conspicuously directed to the sanitary condition of the Alnwick and Canongate urban district, both on account of its excessive mortality and by reason of reports of successive officers of health, who have resigned with exceptional frequency. And finally, the depositions taken at an inquest went to show that the conditions attaching to certain common lodging-houses indicated a state of grave sanitary neglect. The population was 6691 in 1881, and it consists to an unusually large extent of labourers, navvies, tramps, hawkers, and the like, who find accommodation in lodging-houses maintained largely by keepers of Irish nationality. Alnwick has a somewhat important sanitary history. It was inspected in 1849 on behalf of the General Board of Health, and was found to be marked for its wet surface, damp subsoil, and absence of artificial drainage, besides conditions as to arrangement of houses on areas which prevented even the most ordinary circulation of air about them. But in 1850 certain important improvements, including the sewerage of the town, were carried into effect. In 1866 Dr. Buchanan visited the town in connexion with the important report which he subsequently wrote on the relation of phthisis mortality to conditions of soil-wetness, and he found, in addition to the improvements already referred to, that others of importance, including the provision of a public water service, had been effected. But the actual results of these improvements were found to be in the main disappointing in so far as the mortality had been influenced. The general mortality rate had only fallen from 26·2 to 24·7 per 1000; there had been a reduction as to typhoid fever and diarrhœa from 1·35 to 0·87, and from 0·70 to 0·47 per 1000 respectively. But on the other hand, the rate from consumption had risen from 2·83 to 3·30, and that from other lung diseases from 2·80 to 4·05. Mr. Spear now tabulates the mortality returns from a number of specified diseases down to the end of 1883, and it is found that phthisis has made a still further increase in the magnitude of its rate, whereas the rate for other lung diseases remains practically where it was. The fact is, in the first instance, that the works of drainage effected in Alnwick did not, as elsewhere, succeed in reducing the level of the subsoil water beneath the town, and it has been just in proportion to such lowering that the reduction of the phthisis mortality has taken place elsewhere. But although Alnwick effected improvements some thirty years ago, the place has stood still since, if indeed it has not actually deteriorated as regards its sanitary state, and the lamentable account given by Mr. Spear of the crowded courts and alleys; of the absence of control exercised by the authority over the increasing amount of overcrowding; of the mingling together of houses, stables, middens, pigstyes, and the like; of dwellings built right into the damp earth; and of the disgraceful conditions existing in common and other lodging-houses, amply suffice to explain why a disease such as phthisis, which is so favoured by the conditions of crowding and want of fresh air referred to, has increased rather than diminished. The report embodies a long description of places such as have been referred to; and although it also contains an account of some excellent dwellings erected for the poor and of baths and washhouses, all provided by the Duke of Northumberland, yet such improvements are all but ineffectual in the face of the long-standing sanitary neglect in other matters. The secret of the neglect as regards house accommodation is, however, apparent from the report itself. Individual interests among members of the Town Council have paralysed the sanitary administration. This is why, according to Mr. Spear, so many dwellings entirely unfit for habitation are not dealt with; why building and rebuilding in crowded yards cannot be effectively stopped; why stables, middens, piggeries, and a hundred other nuisances remain undealt with. And even where nothing but a trivial alteration is needed the authority appears to stand idle. Thus, notwithstanding the immense danger now known to attach to a system by which there is a direct connexion between the interior of watercloset pans and the interior of the water mains, the sanitary authority have failed to take the necessary remedial action. And why? Because, says Mr. Spear, it would have required owners of property to provide so small a thing as the necessary flushing boxes for closets, and, "shrinking from this duty," they have "staked the health of the whole town on a mere chance." It is lamentable in these days, when so much importance is attached to the extension of the principle of local self-government, to read a report like this, in which, notwithstanding recurring elections to the Town Council, such a town as Alnwick can so long have had an authority tolerating such neglect as is now recorded, and all because those whose duty it is to act for the public benefit have "failed to hold the balance justly between individual interests and the interests of the town." In so far as the housing of the poor is concerned, it is to be hoped that Sir Charles Dilke has brought this report under the notice of his fellow-commissioners, and there are other respects in which the case merits the attention of the central government.

---

REPORTS OF MEDICAL OFFICERS OF HEALTH.

King's Norton Rural District.—Exclusive of deaths of non-residents in public institutions, this district had in 1884 a death-rate of 14 per 1000, the zymotic rate being 0·8 per 1000. Although there was much small-pox in Birmingham during the year, no spread occurred in this rural district. Occasional importations were isolated in hospital, and, for the rest, the district has been protected, as the result of the efficient labours of the vaccination officer. Scarlet fever was also isolated in hospital, and, although twenty-four cases came under observation, no death occurred. The need for such construction of ashpit privies as will be free from nuisance is evidently very great, and Mr. Hollinshead is looking for the remedy in the new bye-laws which are under preparation. These will, of course, only affect new structures; but where sanitary authorities issue new diagrams and plans showing the form of closet permissible under bye-laws, it is astonishing to find how many of the older closets are in time altered according to the pattern indicated. It must, however, be remembered that a proper closet implies a small receptacle for filth, and the latter necessitates frequent removal of contents. Where an adequate system of scavenging is not in operation, people will never put a proper limit on the capacity of their privies, and before the new closets are constructed we advise the authority themselves to arrange a scheme which shall give every house at least a weekly visit, wherever the population is considerable.

Huddersfield Urban District.—During the fifty-three weeks included in the statistical year 1884, the death-rate for Huddersfield was 19·5 per 1000, and it is evident that on a long series of years there has been steady improvement in this respect. The rate from the seven principal zymotic diseases was 3·15 for the previous six years; in 1884 it was 2·38. The diarrhœa death-rate for the third quarter of the year, although not absolutely high, was nearly a tenth of the total mortality for that quarter, and it is to the high temperature and scanty rainfall that the result is in the main attributed by Dr. Cameron. But diarrhœa was more prevalent in 1882 than it was in 1884, and possibly this was due to the precautionary measures now adopted. Wherever a fatal case of diarrhœa was heard of, hose and pipes were at once sent to flush out the local drains, and all accumulations were at the same time removed. Thus, in an important sense the drawback attendant upon scanty rainfall was made good by the authority's officers. Enteric fever also became prevalent in the fourth quarter of the year; but the system of notification worked well and smoothly, and the great improvement effected in the hospital provision came in useful. Of 67 cases reported, no less than 47 were admitted into the Birkby Hospital, and following on this came a system of disinfection for the local drains. Under the compulsory Act, 234 cases were reported. Of these, 118 were cases of scarlet fever, and 91 of them were removed to hospital. The Act is again reported to have worked smoothly. The system of house-to-house inspection which has been in operation, and which is so deservedly regarded as one of the most important duties which sanitary officers can carry out, was temporarily suspended owing to changes in the staff. Much valuable work of a very similar sort was, however, effected as the result of the information acquired by the system of notification.

Brentford Urban District.—Sewers have now been laid throughout the district, and during the past year the work of making the house connexions has been in progress. At the same time sanitary defects which these works disclose are remedied, cesspools are filled in, and other sources of danger to health are abated. Some nuisance having been experienced from the sewer manholes, ventilating shafts have been erected, and during the warm weather hand flushing was resorted to. A first step has been taken to provide means of isolation by the erection of a Doecker hospital hut, but the present site is not regarded as permanently decided on. The annual death-rate was low—namely, 12·28 per 1000; that from the principal zymotic diseases was 1·2 per 1000. The estimated population is 12,307.

Holsworthy Rural District.—On a population of some 9000 the birth-rate for 1884 was 30·8, and the death-rate 16·5 per 1000. The only deaths coming within the group of the principal zymotic diseases were 4 from diarrhœa and 6 from whooping-cough. During the spring and early summer a smart epidemic of sore-throat, which Mr. Linnington Ash did not regard as diphtheritic, occurred in Holsworthy town. It was attributed to emanations from the sewers, the gully traps having become unsealed in the streets, owing to the combined effect of drought and strong north-east wind. In Ashwater much the same sort of disease occurred during the third quarter of the year. The affection was distinctly *infectious, but it was not regarded as either diphtheria or* scarlet fever. It caused no deaths. Improvements as to the water-supply of the district are steadily in progress, but much remains to be done in this respect, especially in Holsworthy town, which is dependent on surface wells liable to become dry during drought, and is also subject to the risk of pollution. This matter has been referred to before in the annual reports, and the time has come when the authority should take it in hand with a view of providing the inhabitants with a proper supply of one of the first necessaries of life.

Llanelly Rural District.—Dr. Raglan Thomas reports a diminution in the amount of epidemic prevalences, and in part he regards this as due to the system of paying a small fee to medical practitioners who have voluntarily reported fresh outbreaks. When such reports come in a searching inquiry is at once made, as is indeed indicated by a lengthened tabulated *résumé* of the conditions discovered. It would be still more interesting if, on future occasions, a column were to indicate the action which had been taken as the result of the discoveries made. Bye-laws now provide for the removal of all privy accumulations twice a week, but, as is often the case, people who are without sufficient garden ground are unable to comply with the regulation. Where this is the case the authority should regard it as its own duty *to effect the scavenging with the needed regularity and* frequency, instead of imposing the obligation on occupiers. A curious instance of water poisoning by zinc came under notice in connexion with the use of the Cwmfelin water. A very pure water had, by virtue of the dissolved oxygen and carbonic acid naturally present in it, taken up 6·4 grains of carbonate of zinc per gallon. This result, which is described by the analytical chemist as unique in his experience, was brought about by the use of so-called "galvanised" water pipes. Boiling causes precipitation of the zinc. Dr. Thomas still deplores the absence of an infectious hospital in his district. The death-rate for 1884 was 15·6 per 1000 living.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5872 births and 3967 deaths were registered during the week ending the 28th ult. The births exceeded by 58, and the deaths by 340, the average weekly numbers during 1884. The annual death-rate in these towns, which had been equal to 20·6, 22·1, and 23·5 per 1000 in the preceding three weeks, declined again last week to 23·2. During the first twelve weeks of this year the death-rate in these towns averaged 22·6 per 1000, against 24·6, the mean rate in the corresponding periods of the nine years 1876-84. The lowest death-rates in these towns last week were 17·8 in Portsmouth, 18·0 in Derby, 18·5 in Bradford, and 18·7 in Brighton. The rates in the other towns ranged upwards to 31·2 in Manchester, 31·7 in Newcastle-upon-Tyne, 33·9 in Oldham, 40·4 in Sunderland, and 41·9 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased from 377 to 443 in the previous four weeks, further rose to 451 last week; they included 176 from measles, 124 from whooping-cough, 37 from "fever" (principally enteric), 37 from diarrhœa, 31 from scarlet fever, 25 from small-pox, and 21 from diphtheria. No death from any of these zymotic diseases was recorded last week in Brighton, whereas they caused the highest death-rates in Newcastle-upon-Tyne, Cardiff, and Sunderland. The highest death-rates from measles occurred in Huddersfield, Newcastle-upon-Tyne, Cardiff, and Sunderland; from whooping-cough in Preston, Cardiff, and Oldham; and from "fever" in Newcastle-upon-Tyne, Preston, and Norwich. The 21 deaths from diphtheria in the twenty-eight towns included 11 in London, 3 in Cardiff, and 2 in Portsmouth. Small-pox caused 47 deaths in London and its outer ring of suburban districts, 2 in Sunderland, 1 in Manchester, and 1 in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding five weeks from 1223 to 830, had increased again to 865 on Saturday last; and the admissions, which had been 94, 104, and 137 in the previous three weeks, further rose to 179 last week. The Highgate Small-pox Hospital contained 94 patients on Saturday last, the admissions in the week having been 31, a higher number than in any previous week of this year. The deaths referred to diseases of the respiratory organs in London, which had been 374, 455, and 487 in the preceding three weeks, declined again to 448 last week, and were 69 below the corrected weekly average. The causes of 121, or 3·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, and in three smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Preston, Hull, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 24·4 and 24·2 per 1000 in the preceding two weeks, further declined to 23·3 in the week ending the 28th ult., and was almost identical with the rate (23·2) during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·6 and 14·1 in Leith and Greenock, to 22·0 in Paisley and 29·9 in Glasgow. The 568 deaths in the eight towns included 32 which were referred to whooping-cough, 18 to measles, 12 to diarrhœa, 6 to "fever," 4 to scarlet fever, 1 to diphtheria, and not one to small-pox; in all, 73 deaths resulted from these principal zymotic diseases, against 88 and 85 in the preceding two weeks. These 73 deaths were equal to an annual rate of 3·0 per 1000, which was 0·4 above the mean rate from the same diseases in the twenty-eight English towns. The deaths from whooping-cough, which had been 22 and 35 in the preceding two weeks, were 32 last week, and included 17 in Glasgow, 5 in Dundee, and 3 in Greenock. The 18 fatal cases of measles showed a decline of 10 from the number in the previous week; they all occurred in Glasgow. The 12 deaths attributed to diarrhœa showed an increase of 6 upon the number in the previous week, and exceeded by 3 the number in the corresponding week of last year. The 6 deaths referred to "fever" included 3 in Edinburgh and 2 in Glasgow; while all the 4 fatal cases of scarlet fever occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 122 and 124 in the previous two weeks, were 122 last week, and exceeded the number in the corresponding week of last year by 5. The causes of 71, or more than 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 32·7, 39·5, and 34·6 per 1000 in the preceding three weeks, further rose to 40·4 in the week ending the 28th ult. This is a higher rate than has prevailed in any previous week of this year. During the first twelve weeks of this year the death-rate in the city averaged no less than 34·1 per 1000; the mean rate during the same period did not exceed 21·6 in London and 20·3 in Edinburgh. The 273 deaths in Dublin last week showed an increase of 39 upon the number in the previous week, and included 32 which were referred to the principal zymotic diseases, against 30 in each of the preceding two weeks. Of these 32 deaths, 12 resulted from measles, 7 from scarlet fever, 6 from "fever" (typhus, enteric, or simple), 3 from diphtheria, 2 from whooping-cough, and 2 from diarrhœa. The annual death-rate from these principal zymotic diseases was equal to 4·7 per 1000; whereas the rate from these diseases last week did not exceed 2·5 in London and 1·7 in Edinburgh. The fatal cases of measles in Dublin, which had been 11 and 16 in the previous two weeks, declined again to 12 last week. The deaths from scarlet fever and diphtheria, on the other hand, exceeded those returned in any recent week. The 6 deaths from "fever" showed an increase of 3 upon the low number in the previous week. Seven inquest cases and 8 deaths from violence were registered within the city; and 85, or nearly a third, of the deaths were recorded in public institutions. The 51 deaths of infants exceeded the number in any previous week of this year, and those of elderly persons were also numerous. The causes of 38, or 14 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

We understand that in view of the necessity for an increase in the Army Medical Staff, the Secretary of State for War has decided to grant appointments to all the candidates who, at the late competitive examination, obtained the necessary qualifying marks, but were excluded in consequence of being beyond the number required to fill vacancies. This will provide an addition of about thirty-eight officers to the Department.

We note that a telegram having been received recently by Her Majesty's Secretary of State for India from the Government of India, requesting that all officers in military employ on furlough may be directed to rejoin their regiments or appointments, instructions to this effect were issued on the 25th ult. to all medical officers, as also to combatant officers, of the Indian army to proceed to Brindisi in time to join the Peninsular and Oriental Company's mail steamer there on the 6th inst.

INDIA OFFICE.—The Queen has approved of the following admissions to her Majesty's Indian Medical Service:—John Tasman Waddell Leslie, David Prain, Arthur Thomas Bown, Upendra Nath Mukerji, and William Locking Price, to be Surgeons in the Bengal Army.

ADMIRALTY. — The following appointments have been made: Staff-Surgeon James Dunlop, M.D., to the *Ruby;* Surgeon Herbert Canton, to the *Ruby;* Staff-Surgeon Albert C. Traceby, to the *Mercury;* Surgeon Edward R. T. Fasker, to the *Shannon*, additional; Surgeon Edward H. Williams, to the *Cockatrice;* Surgeon Penrose J. Barcroft, to the *Imogene;* Herbert M. Sweetman to be Surgeon and Agent at Schull; and Francis Rennie, M.B., to be Surgeon and Agent at North Shields; Staff-Surgeon Albert C. Queely, to the *Mercury;* Thomas W. Fryer to be Surgeon and Agent at Gerran's Bay; George W. Hill to be Surgeon and Agent at St. Mawes and St. Anthony.

ARTILLERY VOLUNTEERS.—1st Lancashire: Thomas Moore Dawson, Gent., to be Acting Surgeon.

ENGINEER VOLUNTEERS.—1st Newcastle-on-Tyne and Durham: Surgeon John Wilson resigns his commission.

RIFLE VOLUNTEERS.—1st Clackmannan and Kinross: Peter Rough, Gent., M.A., M.B., to be Acting Surgeon.—2nd Volunteer Battalion, the Lincolnshire Regiment: Surgeon and Honorary Surgeon-Major Edwin Morris, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement.

THE LATE GENERAL GORDON.—We understand that the *Boy's Own Paper*, of the Religious Tract Society, whose readers have already subscribed over £1200 for two lifeboats, besides £400 for a hospital cot, is promoting a Boys' Gordon Memorial on the lines known to be dear to Gordon himself—viz., to help the poorer working and suffering lads.

Correspondence.

"Audi alteram partem."

THE NEW EDITION OF THE NOMENCLATURE OF DISEASES.

To the Editor of The Lancet.

Sir,—The second edition, being the first revision of "The Nomenclature of Diseases," is now in the hands of the profession. A memorandum of the Subcommittee on Classification inserted therein quotes the first line of the preface of the first edition, which declares "the perfecting the statistical registration of diseases" to be the object of the undertaking, and then significantly adds, "this object has certainly not been as yet attained." I think the bulk of the profession will so far agree with the subcommittee in this expression of opinion, for it will doubtless assume that the prefatorial memorandum was written, as is customary, after the rest of the work was in type.

"To-morrow the critics will commence—men who have failed in literature and art," some members of the subcommittee may possibly say, quoting Lord Beaconsfield. To them the painstaking registrar will reply, in the words of a still greater authority, "I am nothing, if not critical."

May it not be possible, for instance, for cases of "frostbite" to occur in this variable climate of ours? One such accident comes under the notice of our conscientious statistician, who wishes to notify the same in an orderly manner. He turns to his copy of "The Nomenclature," which a parental Government has just forwarded him, and looks out "frost-bite" in the index. He is referred to pp. 193, 215, 217, 223. He opens the volume at p. 193, and finds the ailment in question placed under diseases of the skin. He turns to page 215, and perceives it inserted under general injuries with a note as to its limitations. At page 217 it is placed amongst the local injuries, and at page 223 along with injuries to the skin. If this arrangement (?) is insufficient to produce the bewilderment necessary for statistical purposes in the brain of our conscientious statistician, I may yet add a further section, wherein "frostbite" can have a place, and that will be found at page 12—"Effects of cold." Somewhat similar results would be the outcome of attempts to classify the other "effects of climate, &c." recorded in the nomenclature. I shall not, however, encroach on your valuable space by recapitulating them.

A casual perusal of the volume in question has, however, brought to light the following further peculiarities—e.g.: Alcoholism (p. 12) is a disease of diet; alcohol (chronic poisoning by) (p. 203) is included among the poisons; mercurial tremor may be either a disease of the nervous system (p. 27), or the result of a poison (p. 199); syncope is both a disease of the nervous system (p. 29) and one of the circulatory system (p. 71); ranula occurs twice (pp. 89—99); chromium is the only metal whose salts are given in the section (p. 199); phosphorous acid is a poison; nitrous and sulphurous acids are not given (p. 201); sulphate of indigo is named (to use a parliamentary expression) in the short list of poisonous acid salts (p. 201); picric acid is called by the discarded name carbazotic acid (p. 203); elephantiasis (p. 123) is classified as a proliferation tumour, whether it is evidently caused by the presence of the parasite filaria sanguinis or not; we also learn that this disease is a variety of "diffuse fibroma" (p. 309); tubercle is a variety of granulation tumour (p. 313); gonorrhœa is a disease of the whole body (p. 11); gleet (gonorrhœa mucosa) is a disease of the male organs of generation, unless it is caused by gonorrhœa (p. 135). In the first edition, gonorrhœa was placed amongst diseases of the urinary system. "Amyloid," the synonym of the rarely-used term "lardaceous," is frequently omitted—e.g., pp. 3, 105. The following diseases and synonyms are omitted: Comedones, area Celsi, Duchenne's paralysis, Jacksonian epilepsy, amyotrophic lateral sclerosis, and many other well-known nervous diseases. Fetid bronchitis, malignant endocarditis, peritonitis due to gonorrhœa, perimetritis and parametritis are not inserted in the index, although they occur on page 147.

Many fairly common poisons are also omitted—e.g., croton chloral hydrate, paraldehyde, &c. Finally, "morula" (O tempora! O morula!) is the Latin equivalent for "yaws." One would almost imagine that our classic must have been pleading with the printer's devil for a "brief respite" from the latter's too persistent visits for "copy" when he substituted "morula" for the time-honoured "frambœsia," although the latter's derivation from the French (alluded to by Bateman) is scarcely classical.

I am, Sir, yours obediently,

Brighton, March 30th, 1885. W. Ainslie Hollis.

FORENSIC MEDICINE.

To the Editor of The Lancet.

Sir,—I have waited in the hope of seeing letters from more experienced writers and abler pens than mine confirming the remarks of your able leader of March 7th. There are, according to the Medical Directory, fifty-one medical coroners in England and Wales out of a total of 281. The subjects of forensic medicine and coroners' inquests penetrate every nook and cranny of medical practice in England, Wales, and Ireland; and, though there is no coroner's inquest in Scotland, the subject of forensic medicine has received more practical attention there than in any other part of the United Kingdom. I am surprised, therefore, that no notice has as yet been taken of your leading article by some of the many who are so capable of dealing with it. Having in the course of the last twenty years made many post-mortem examinations for different coroners, and taking great interest in all medico-legal cases, I am in a position to confirm the remarks in the second part of your article.

There is a very forcible reason why two examiners should always be employed in cases involving a criminal charge, which you have omitted to notice. One may be ill or even dead when the trial comes on, and if he has been unassisted there is no one to give evidence or to be cross-examined. It is true that the depositions before the coroner and magistrate are in court and can be read, but anyone who has attended trials must know what a very unsatisfactory substitute for a witness are his depositions.

Another point which can hardly be ignored is the importance of a division of time and labour. I know nothing more fatiguing than making a post-mortem examination of an adult corpse, completely and satisfactorily, by oneself. Even in a hospital dead-house, with every convenience, it means time and work; but in the dwellings of the poor, without any convenience whatever, and with the body lying on the floor, it becomes as hard a task as can well be undertaken.

The importance of expert evidence in criminal cases will be seen by a reference to recent trials. In the Penge case the question was simply, Did the deceased die from starvation or natural causes? and had there been present at the autopsy one of the many experienced pathologists attached to the metropolitan medical schools, most of the difficulties of the case would have vanished. In two cases which occurred recently in Manchester, the evidence of Dr. Cullingworth, the lecturer on Forensic Medicine at Owens College, was most important; strengthening the case for the prosecution in one and disproving a groundless charge in the other. And in all cases which are likely to proceed to a higher court it is obviously desirable that the coroner and medical witness should have the benefit of a second opinion—i.e., of an expert, well experienced in post-mortem examinations, and with a competent knowledge of forensic medicine.

Another matter which you have not noticed is that the coroner in a certain proportion of the cases which come before him has absolute discretionary power in the selection of a medical witness, none having been called in either before or after death. Hence, in all these, he is at liberty to employ an expert without any encroachment upon the rights of general practitioners. And it is these unappropriated cases, as they may be called, which might be utilised for the study and practice of forensic medicine. In 1861 the chair being then vacant, the late Dr. Ayrton, who was generally chosen by the coroner at that time to make all post-mortem examinations for him, was appointed the lecturer on medical jurisprudence at our local medical school, and it was hoped that the appointment would enhance the interest of the lectures. Dr. Ayrton only lectured, however, for one session, and the experiment was abortive. In a paper read before our medical institution in 1876 on the "Coroner's Court," I attempted to show how it might be rendered more effectual in providing "the more efficient performance of all medico-legal autopsies and a field for the practical study of forensic medicine in our medical schools." Referring to the latter, I observed, "In a word, every department of medicine should be taught and learned 'practically.' Why should forensic medicine be any exception to the rule? Within a distance of very little over a mile from the Royal Infirmary is a place which affords a field for the practical study of forensic medicine little inferior to the Morgue of Paris, where world-renowned medical jurists, Orfila, Devergie, and others, acquire their reputation. I refer to the dead-house, Prince's Dock, where cases of death from drowning, burning, suffocation, exposure to cold, and infanticide, may be seen in almost every variety. ...... Now, without encroaching upon other gentlemen's province, the students of the Royal Infirmary School of Medicine (now the Medical Faculty, Liverpool University College) might have many opportunities afforded which they do not now possess. During the summer session the lecturer on forensic medicine might, I am sure, easily obtain permission of the authorities to visit this place and show the external appearances of death from the various causes I have indicated as to be met with there." The suggestion was favourably received by those present at the meeting, which included Dr. Ewing Whittle, then, and until very recently, lecturer on medical jurisprudence. But changes are not easily made, and so far nothing has been done. Mr. F. T. Paul, a most experienced pathologist, has just been elected to the vacancy, and I trust that he will be afforded every reasonable opportunity of both practising and teaching forensic medicine.

With regard to toxicology, it seems to me to be very important that students should be taught the detection of poisons in urine, vomited matters, &c., although the more elaborate examination of these, as of viscera, must be left to the analytical chemist. But the medical practitioner is the first on the spot, and it is his accurate observation of facts and symptoms which leads to detection. In the Edinburgh opium poisoning case, which occurred some years ago, it was reported that some spots on the nightdress of the deceased were detected by the chief medical witness as caused by laudanum having been spilled. This single fact proved a most important piece of evidence, as the case presented all the usual difficulties of opium poisoning. In the Lamson case the careful preservation and analysis of the matters first vomited were the most important links in the chain of evidence against the prisoner. Much, if not all, the mystery of the Bravo case would have been dispelled by a careful analysis of the urine, fæces, and vomited matters while the unfortunate deceased was still living. More important than analysis is the careful observation of symptoms, and comparing them with those of poisoning. In the recent cases of murder by arsenic in this city it was shown by the confession of one of the prisoners that eleven deaths were due to arsenic administered by one or both of the accused persons. All these persons had been attended by medical practitioners, and the deaths had been duly certified. How many more victims might have fallen had not the death of Thomas Higgins excited Dr. Whitford's suspicion, it would be hazardous to guess; but the case shows the importance of careful observation. It was the sudden nature of the death which excited Dr. Whitford's suspicion, though in the miserable surroundings of the case he failed to see any motive for foul play until he heard that the life of the deceased, a poor bricklayer's labourer, was insured to the extent of £100.

I could have added more were this letter not already too long. I conclude with the hope that the defects you have indicated will be remedied, and that forensic medicine will become, as so interesting a subject deserves to, a thoroughly practical and attractive branch of medical study.

I am, Sir, yours faithfully,

Liverpool, March 25th, 1885. FRED. W. LOWNDES.

PHYSIOLOGY IN OXFORD.

To the Editor of THE LANCET.

SIR,—You have thought fit to accuse those who recently opposed the grant to the Physiological Laboratory at Oxford of misrepresentation, recklessness, injustice, and an unwarrantable use of personal allusion. As all the circulars and notices issued by the opponents of the grant passed through my hands, I ask you to allow me to repudiate your accusation as emphatically as possible, and in enclosing you the documents in question I challenge you to point out one single sentence containing a misrepresentation, a reckless or unjust statement, or any personal allusion which an official position does not warrant. Two concessions only were asked of Professor Sanderson—viz., that he would not hold a certificate to dispense with anæsthetics, nor one to free him from the necessity of killing the animal.

Now, if the promoters of the grant had said openly, "Away with such restrictions and concessions; they are an insult!" the opponents of the grant, however much they might have regretted such a declaration, would have respected it as the bold challenge of a candid antagonist. But in the circular issued in advocacy of the grant, and in the debate in Convocation, the arguments used were, "There are to be no painful experiments on living animals, either with or without anæsthetics. The grant is only for coal, gas, and water." You, Sir, know well that there may and will be painful experiments on living animals without anæsthetics within that laboratory *for purposes of research*, and to say, as was said, "There will be none for purposes of demonstration and instruction," and at the same time to suppress all allusion to experiments for research, is an act of "aggressive concealment" unworthy of those who believe they have a good case.

I am, Sir, your obedient servant,

FREDERIC E. WEATHERLY, M.A.

Brasenose College, March 28th, 1885.

⁂ Mr. Weatherly cannot be ignorant of the fact that the cause he advocated received some of its most powerful support from others than those immediately concerned in the voting at Oxford. Our remarks did not apply to the phraseology of the circulars with which he has favoured us.—ED. L.

INSANITY AFTER OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—It would seem desirable that every case in which ovariotomy has been followed by insanity should be recorded.

Some years ago, in Sydney, I removed a large ovarian cystoma from a widow aged about forty. I have not brought the notes of the case with me, and cannot therefore give her exact age. Three days after the operation she became insane, and, unlike most of the cases related by the speakers upon this subject at the last meeting of the Clinical Society, the disease became chronic, and it was found necessary to confine the patient in the asylum at Gladesville. The disturbance of the mental balance in this case, I thought, was due to the sudden and violent change from extreme mental depression to excessive joy. The patient had quite made up her mind that she should die under the operation, and had given directions as to the conduct of her funeral. Her extreme astonishment when she recovered from the effects of the anæsthetic at finding that she was not only living, but rid of her burden, I shall not soon forget. I should state that there was no family history of insanity.

I am, Sir, yours obediently,

Sydenham-hill, March 30th, 1885. P. SYDNEY JONES.

HICKS *v.* BEDFORD AND OTHERS.

To the Editor of THE LANCET.

SIR,—Dr. Rogers, in his interesting letter published by you on March 21st relating to this case, draws attention to a very important passage in Mr. Justice Wills' charge to the jury. The quotation given is that "there is no statutory power whereby anyone, lunatic or otherwise, can be detained in a workhouse against his will." As Dr. Rogers points out, this ruling must cause a very great surprise to those concerned in workhouse administration, as it declares illegal a practice which has gone unchallenged for upwards of forty years at least. But this particular paragraph, at any rate, is not in accordance with the Poor-law Amendment Act of 1867, 30 & 31 Vict., sec. 22 of which states: "When there shall be in any workhouse a poor person suffering from mental disease, or from bodily diseases of an infectious or contagious character, and the medical officer of such workhouse shall, upon examination, report in writing that such person is not in a proper state to leave the workhouse without danger to himself or others, the guardians may direct the master to detain such person therein, or, if the guardians be not sitting, the master of the workhouse may, until the next meeting of the guardians, detain him therein, and *such person shall not be discharged from such workhouse until the medical officer shall in writing certify that such discharge may take place;* provided, however, that this enactment shall not prevent the removal of a lunatic to a lunatic asylum when such removal is otherwise required by law, nor the removal of any poor person after the parent or next of kin of such person shall have given to the guardians such an undertaking as they shall deem satisfactory to provide for the removal, charge, and maintenance of such person with due care and attention while the malady continues."

It is the practice at the Stoke-on-Trent Union Workhouse, where I am medical officer, for certificates to be signed by myself, the master, and the clerk to the guardians, when it is thought necessary to detain any person suffering from mental or infectious disease, and I have on more than one occasion thus detained patients convalescing from scarlet fever and cases of delirium tremens. I enclose our form of certificate, which is drawn up in strict accordance with the Act of Parliament.

I am, Sir, yours obediently,

Stoke-on-Trent, March 30th, 1885. J. G. UVEDALE WEST.

THE HISTORY OF THE USE OF IPECACUANHA IN DYSENTERY.

To the Editor of THE LANCET.

SIR,—Dr. Macpherson's paper on the above subject, read at the meeting of the Medical Society on March 9th, was one of great interest. It would appear, however, that it was left to Sir Joseph Fayrer to recall the fact that it was to Mr. Docker we owed the introduction of the remedy into the practice of the British army and the reduction of its employment to a system. Sir Joseph Fayrer was right in thus giving honour to whom honour is due; for, although something may be credited to improved sanitation, &c., there is no doubt that the great decrease in the mortality from dysentery in India in late years is due to the employment of the system of treatment introduced by Surgeon-Major Docker.

Having treated a large number of cases of dysentery with ipecacuanha, *in large doses, during my service in Ceylon,* India, and British Burmah, I can bear testimony to its great efficacy in acute cases, a few twenty-grain doses bringing the disease promptly to a termination, when treated at an early period, as stated by Sir Joseph Fayrer. I can also bear out Dr. Cullimore's belief that "in dysentery associated with hepatic disease ipecacuanha, in large doses, is not well borne." Dysentery is frequently found associated with, or dependent on, hepatic congestion. My latest experience of the treatment of such cases was given in a paper in the *Indian Medical Gazette* of July 1st, 1881; and as the passage bearing on the treatment of this complication is short, and the subject one of much interest, I beg leave to quote it:—"When dysentery is present, complicating the hepatic congestion, I have found the treatment suggested at page 52 of my book successful—viz., a mixed treatment of alternately giving ipecacuanha (twenty to thirty grains) and chloride of ammonium until the relief of the dysentery, or a full midday dose of ipecacuanha, or the latter in enemata should there be fear of vomiting, with morning and evening doses of the chloride, or in some cases a midday dose of the chloride may be preferable, and morning and evening doses of the ipecacuanha, until the dysentery is checked. In such cases the patient, if asked, will express himself as receiving great relief from pain by the exhibition of the chloride; and, if so, it may be well to give it more frequently than here recommended." I am, Sir, yours, &c.,

WM. STEWART, M.D.,
Surgeon-General, A.M.D. (retired).

Mount Pleasant, Lymington, March 23rd, 1885.

AN anonymous donor has intimated to the Committee of the Sheffield Hospital and Dispensary his desire to endow a bed in the institution, in memory of the late General Gordon, on condition that it shall be known for ever as the "Gordon Bed." The endowment is thirty guineas a year, which the donor will pay for some time, and then invest capital with trustees sufficient to raise the amount annually required in perpetuity.

THE GORDON MEMORIAL HOSPITAL.

(*From a Correspondent.*)

THE choice of Port Said for the proposed establishment of a Gordon Memorial Hospital appears to be adversely commented on by professional and public opinion in Egypt. It is strongly urged that by far the most suitable place is Alexandria. It is the seaport of Egypt, the centre of commerce, and has a population of nearly 200,000.

Port Said is an outlandish insanitary little town, with only 12,000 people, of whom about six families are English. There is no highway to it from any part of Egypt except from Suez by the Canal, and ships passing through the Canal do not stop at Port Said. Nor is there any railway communication with it, so that a hospital there could benefit only an odd seaman landed from a passing vessel, or, perchance, a stray traveller.

In Alexandria, on the other hand, with its extensive shipping, as the import and the export city of Egypt, a large number of British seamen every year are landed for resident treatment in a hospital. For this they have to depend on foreign institutions, and are attended by nurses that do not always speak their language. English residents, also, in the towns and villages of Egypt, that have no real home where they can be attended to during sickness, go to hospital in Alexandria as the commercial centre, and could not go to Port Said for want of railway communication.

In Alexandria the English residents contribute most liberally to a foreign hospital. In it hundreds of merchant seamen, many officers and men of the British Army and Navy, and Englishmen without home comforts, are treated by the English doctor, who is one of the visiting surgeons. In the same hospital, and by the same doctor, 200 or 300 Egyptians are treated annually as in-patients, besides some 20,000 out-patients. This success is almost entirely due to the ability and energy of the English doctor. Natives (Egyptians, Bedouins, and Soudanese) flock from far and near, attracted by the reputation that English surgery has won in his hands; and while they gravitate to a centre like Alexandria, with a surgical fame already declared, they never would go to Port Said, where the essentials of success do not exist, and where a fine institution, after an ineffectual flicker, would soon dwindle down into a fourth- or fifth-rate cottage hospital.

The success in attracting natives is a most important point, for it must be remembered that Gordon, to whose beloved and honoured memory a hospital is to be erected in Egypt, was, above all things, catholic, and gave his life for Mussulmans.

It is to be hoped that this matter will receive the anxious consideration of the Memorial Committee, if they desire an institution that will really honour the blameless and heroic life of General Gordon, and that will be a credit to its founders.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

DR. DALLINGER IN NEWCASTLE.

DR. DALLINGER delivered a lecture last week in our Literary Philosophical Institute which will not be soon forgotten. The subject, I need scarcely say, was treated in a most masterly and advanced manner by the reverend lecturer. The title of his subject was "On a New Putrefactive Organism, with some Deductions concerning the Group," but the mere title gives but a faint idea of the extent of ground covered by the reverend and learned lecturer's discourse, which was of a deeply interesting character, and well illustrated by the oxyhydrogen lantern. He showed certain nomads that he had discovered by a powerful microscopic lens, rectified by the modern employment of various essential oils as corrective media of refractive errors. He dwelt principally on septic organisms, and went fully into the source and life of these nomads, how they were produced in water where animal matter was decomposed, and by such decomposed animal matter became reproduced into a new form of life. He urged upon biologists of the district the study of the bacteria, so that the various forms might be followed out, and the fullest information on the subject obtained, which, he said, was of the greatest importance to the human race.

THE FLEUSS APPARATUS.

The local papers are much taken up with letters and inquiries about the Fleuss apparatus. It is felt that if such had been in readiness after the explosion at Usworth the lamentable loss of life by the intrepid explorers might have been avoided, and possibly lives in the future rescued by its adoption. It has been sufficiently shown that the Fleuss apparatus enables its wearer to remain under water or in an unrespirable atmosphere for as long as an hour and twenty minutes. The Fleuss apparatus may be in its essentials thus described. It consists of a mask or mouth-piece, a knapsack, and an elastic bag or air reservoir. The mask fits tightly over the eyes, mouth, and nose, and is held in position by means of straps fastened at the back of the head. The knapsack comprises the gas chamber and the alkali chamber. The gas chamber is a strong cylinder made of sheet copper, 12 in. long and 8 in. diameter, and will contain four cubic feet of oxygen gas at a pressure of 58 lb. per square inch. The alkali chamber is contained in a tin plate case, and is made of vulcanite 12 in. high, 12 in. wide, and 6 in. deep, divided vertically by diaphrams so disposed as to cause the exhaled air to pass through the caustic alkali twice before it is delivered into the fresh air reservoir deprived of all the carbonic acid gas, and the greater part of the moisture or aqueous vapour of the breath. The fresh air reservoir is made of vulcanised indiarubber, which admits of a pulsating movement corresponding to the breathing of the wearer. It is worn on the front of the body extending over the chest and stomach. A flexible inhaling tube is carried over one shoulder and connected to the air reservoir, and the flexible exhaling tube is carried over the other shoulder, and connected to the decarbonating or alkali chamber. The exhaled air, after passing through the alkali chamber, flows into the air reservoir, on the point of entering which it receives the required supply of oxygen, which is regulated by a small valve under the control of the wearer. The apparatus is easily carried, and has the great advantage, besides its efficiency, of leaving the limbs of the wearer free. In an able article in the *Newcastle Daily Chronicle* the moral effect of having the apparatus in readiness is pointed out, and it is believed "that a couple of the apparatus would be of more value than a score of willing explorers—in the event of a colliery explosion—with the courage, but without the means, to successfully combat the insidious effect of the after-damp."

Dr. O'Hanlon, the medical officer of the Spennymoor Local Board District, in his report, points out with regret that the use of opium is increasing in the district, and especially amongst the female population. This is much to be regretted, as the habit could not—up to late years at all events—be considered as established among our northern mining population.

Newcastle-upon-Tyne, March 24th.

EDINBURGH.

(*From our own Correspondent.*)

CLOSE OF THE WINTER SESSION.

THE winter session of the Edinburgh Medical School came to a close on Friday, the 27th ult. There was the usual interest displayed in the summing up of the work of the session by the various lecturers, and the distribution of medals and prizes to successful competitors; although, judging by the small attendance at one or two of the classes, it appeared that many students had already made their escape from college trammels to the enjoyment of a well-earned holiday. This did not interfere, however, with the lively interest displayed in the closing lecture of the class of Clinical Medicine, delivered by Professor Maclagan; for it was widely known that this was to be a valedictory address on his retirement from the chair. Long before the appointed hour the lecture theatre was crowded with students; there was also a large representation of the teachers in the Edinburgh Medical School, many of whom, now occupying important posts of responsibility, had studied under the veteran and genial professor, whom they were now assembled to honour. Professor Maclagan's entrance, supported by his colleagues of the clinical chair, was greeted with a most enthusiastic demonstration of esteem, which was warmly reiterated from time to time as some telling point, some apt illustration or classical quotation, marked the phases of his most interesting address. In a few comprehensive sentences Professor Maclagan reviewed the work done during the session, so far at least as the lectures were concerned, dealing shortly with each system of the bodily mechanism and its disorders, and pointing out the significance of each in the economy of general medicine. In the branch to which he had drawn attention specially—that of diseases of the skin—there had been no lack of interesting cases, and he congratulated the students upon the opportunity which had been afforded them of studying some of the rarer forms—as, for instance, true leprosy. Passing then to the subject of his retirement, Professor Maclagan explained that it had been for some time in contemplation, owing to the completion of the new Public Health Laboratories, to the development of which he was anxious to devote his time and energies, but that at the request of his colleagues it had been postponed until the present time. Speaking of the charm of hospital work both to the scientific physician and to the well-wisher of his fellows, he alluded feelingly to the regret which he experienced in parting from surroundings that had afforded him so many opportunities of pleasurable interest and of usefulness to others, and testified to the warm feeling of personal gratification with which he looked back upon the cordial relations which had always existed between himself and his fellow-workers, be they teachers or students. In dealing with the many phases of hospital work, he drew attention specially to the importance of children's diseases, and of the fevers, for the study of both of which increased facilities are to be provided; and, in meeting the objections which have been urged against the study of the latter, he held strongly that those whose natural bent had led them to encounter the dangers of a medical career should not flinch before an additional risk, by avoiding which they could not enter fully equipped upon the practice of their profession, and that, even here, that Providence under whose care they had prospered so far would still be their protection. Professor Maclagan then took leave of the class over which he has presided so long, his adieux receiving the most enthusiastic response from the students; and there was not one amongst them, as they rose *en masse* and waved a last farewell, but would carry away with him a kindly feeling towards the "old man eloquent," whose well-weighed words had taught him many a useful lesson, and whose gentleness and courtesy had inspired him with feelings of the deepest respect.

A WISE SCHOOL BOARD ELECTION.

The city of Edinburgh is to be congratulated upon the return of an able representative of the medical profession as a member of its newly-elected School Board. The subject of Over-pressure in Board Schools is such a burning question at the present juncture that a School Board which counts a medical man upon its roll will be viewed with much less suspicion by the parents of the oppressed infants than where this is not the case. Although returned as a "ratepayer's candidate," Dr. Russell will doubtless not feel bound to advocate that most fertile source of over-pressure, a minimising of the teachers' emoluments, that makes the straining after large grants essential to their bare existence.

DINNER TO DR. ARTHUR THOMSON.

Dr. Arthur Thomson, the newly chosen lecturer on Human Anatomy in the University of Oxford, was entertained at a congratulatory dinner by the University Assistants' Club, at the Waterloo Hotel on March 27th. Dr. Murdoch Brown occupied the chair, and amongst the guests present were Dr. Thomson, senior, Professor Turner, and Professor T. R. Fraser, Dean of the Faculty of Medicine. After the loyal and patriotic toasts had been given, the chairman proposed "The Health and Prosperity of Dr. Thomson," and paid a warm tribute to the talents as well as to the *bonhomie* which had placed him so high in the esteem of his colleagues. Dr. Thomson responded in an amusing speech. In proposing "The Assistants' Club," Professor Fraser alluded to the importance of a University being distinguished by achievements which extend the area of science as well as by the completeness of its didactic functions, and whilst deprecating the employment of large sums for the endowment of bursaries, which reward their holders for merely doing their duty, he strongly urged that such sums should rather be devoted to defraying the expenses of scientific research, which has been largely crippled through lack of funds amongst those who might otherwise have undertaken such work with the very best results.

Dr. Arthur Thomson is succeeded in his post of Senior Demonstrator of Anatomy by Mr. David Hepburn, M.B., C.M., who has been for three years upon the staff of demonstrators.

PARIS.

(*From our Paris Correspondent.*)

THE DIVULGENCE OF PROFESSIONAL SECRETS.

Dr. **Watelet**, who was fined 100 francs for having divulged a "professional secret" under circumstances referred to in my letter of March 21st, has protested by a letter in a morning paper against the judgment of the Court by refusing to sign a bulletin, a printed form which every medical man receives from the Prefecture of the Seine, and which he is required to fill up on the death of a patient. The bulletin contains as headings: name of the principal disease, final accidents, cause of death, duration of the malady, &c. Dr. Watelet appears to find this demand inconsistent with the charge brought against him, and consequently returned the bulletin unfilled to the Prefect. I am afraid, however, that he will again render himself amenable, as the name and address of the patient are written on a slip of paper which is detached from the body of the bulletin before the latter is sent back to the office of the Prefecture. As I have already observed, the position of a medical man in his relations to society is peculiarly difficult and delicate, for the construction that may be put on the article in question (378 of the French Penal Code) is so elastic that a medical man is never safe, as he may at any moment unwittingly commit himself, as in the case of Dr. Watelet. A striking example of this has just happened to another medical man in Paris. A physician, who was also a pharmacien, but who practised only in the latter capacity, lately died. Dr. Constantin Paul, in announcing the event at a meeting of the Société de Thérapeutique, of which the deceased gentleman was a member, stated that death was caused by tubercular meningitis, of which he had an attack ten years previously. The Insurance Company in which the deceased had insured his life for 200,000 francs, or £8000, having taken note of this circumstance, has refused to pay the widow, on the grounds that her husband's life was insured subsequent to the attack he had ten years before, he being at the time the subject of a fatal malady which eventually carried him off. The case, which is interesting from more than one point of view, is pending, and it is said that if the Insurance Company should persist in their refusal, Dr. Constantin Paul will be prosecuted for divulging a professional secret. Examples of this kind are daily to be met with, for we see in the medical and lay papers full descriptions of maladies of persons of note ante mortem and post mortem. At this very moment the nature of the malady from which General Grant is suffering is being publicly discussed on both sides of the Atlantic, and so was that of General Garfield and M. Gambetta, and yet no one ever dreamt of prosecuting the authors of the published articles.

THE GODARD PRIZE.

The Société de Biologie of Paris has awarded the Prix Godard (1884) to Dr. E. Leblond, for his work on the physiological and therapeutic action of caffeine.

Another election of a corresponding member of the section for Medicine and Surgery of the Paris Academy of Science, took place last week. Sir James Paget, who was elected, received thirty-eight votes, against two for Sir Joseph Lister, and one for Dr. Leudet, of Rouen. Dr. Panum, of Copenhagen, was also a candidate.

Paris, March 31st.

The Association of Public Sanitary Inspectors.—At the next monthly meeting of this Association, to be held April 4th (this day), at 1, Adam-street, Adelphi, at 6 p.m., an address on "Sanitation" will be delivered by Dr. B. W Richardson.

VIENNA.

(*From our own Correspondent.*)

GASTRO-ENTEROSTOMY.

In removing a carcinoma of the pylorus, if too much of the stomach have to be included in the excision, the sutures—especially if of catgut—between the thick gastric wall and the thin duodenum usually relax in consequence of the great tension; for cases in which the stomach cannot be united with the duodenum, Dr. Woelfler has employed gastro-enterostomy in order to prolong the life of the patient. The stomach is united with the coils of the small intestine above the carcinoma, so that the food proceeds direct into the small intestine, eluding the pylorus and the duodenum. The method is only a palliative one, its object being to avert stenosis, as the carcinomatous masses remain behind. Professor Billroth has modified the method in the following manner. He operates like Woelfler, then he excises the stomach, lifts up the carcinoma, unites the viscus with the small intestine, loosens the carcinoma, and finally cuts it off, so that the food proceeds direct into the small intestine, and the duodenum is, so to say, an enormously lengthened ductus choledochus. A few weeks ago Professor Billroth operated in this way on a decrepit patient, who recovered satisfactorily.

DIAGNOSIS OF CARCINOMA.

Mr. E. Freund, a medical student, has described a method of diagnosing carcinoma with very few chemical aids in every stage of its development. He says there is in the blood of carcinomatous individuals a reducible substance, which he supposes to be sugar; and the blood of sarcomatous individuals contains an unusual amount of peptone. In cases of carcinoma diabetes was excluded, as was leukæmia in cases of sarcoma. In both diseases only a very small quantity of blood should be examined. In sixty-two cases of carcinoma, after the albuminous products had been removed with sesquichloride of iron and nitric acid, there was found in 0·3 cubic centimetre of blood a substance which distinctly reduced Fehling's solution. In eight cases the blood had to be heated for a few minutes with dilute muriatic acid, and glycogen, as such, could then be proved. After extirpation the sugar in the blood disappeared; in one case only it persisted, in which relapse took place. In fifteen cases of sarcoma, after the removal of the albuminous contents, peptone could distinctly be found.

TRANSFORMATION OF PUTREFACTIVE BACTERIA.

Professor Stricker recently communicated to the I. a. R. Society of Physicians the information that Professor Spina had succeeded in transforming putrefactive bacteria in the course of two days, and that they show the same behaviour towards methyl-violet as tubercle bacilli. Professor Stricker and Dr. Amrus have repeated these experiments, which corroborate Professor Spina's statements.

THE GENERAL EFFECT OF COCAINE.

In a lecture delivered recently Dr. S. Frend described some experiments he had made to illustrate the stimulating and restorative power exerted by the muriate of cocaine. The exhilarating effect of the ingestion of from 0·05 to 0·10 gramme of the drug lasts four or five hours, and disappears by degrees without being followed by depression. This effect of cocaine can be tested by the dynamometer. Under the influence of 0·10 gramme of cocaine an increase of power of pressure of the right hand of 2 to 4 kilogrammes, and of that of both hands of 3 to 6 kilogrammes, has been registered. This effect ensues shortly after the taking of the drug, and is best shown if it is taken while the system is in a condition of great depression. The daily fluctuation of the muscular strength which takes place in correspondence with the daily fluctuation of the bodily temperature, as shown by Dr. Max Bruch, is also to be taken into account in studying the effect of cocaine on the motor power.

Vienna, March 19th.

MEDICAL NOTES IN PARLIAMENT.

The Insane Poor.

In the House of Commons on the 26th ult., Sir Charle Dilke, in reply to Mr. W. Corbet, stated that the return o poor rates and pauperism just issued does not give th total number of insane persons maintained at the publi ense. The numbers given in that return are of the pauper atics maintained by the guardians at the cost of the poor s, and do not include the insane who are maintained by counties and boroughs at the cost of the county and ough rates. The return which was prepared by the mmissioners in Lunacy and presented to the House in e, 1883, contains, so far as the Board are aware, the est information available on this subject.

Lunatic Asylums in Ireland.

n the 30th ult., in reply to Mr. A. O'Connor, Mr. Campbell-nerman said that there has not been time to ascertain exact present condition of affairs in each lunatic asylum reland, but he believed there is no doubt that in some lums the number of patients is in excess of the nominal ommodation, although, taking the country as a whole, re is more accommodation than is actually required. The d Lieutenant gives immediate and full attention to any resentations made to him on this subject. Several lums have already been extended, and extensions are ng or are about to be effected in others.

Sixpenny Telegrams.

Mr. Shaw-Lefevre stated that it has been decided that the tariff shall come into force on Aug. 1st next.

Small-pox and Vaccination.

n the 31st ult., Mr. G. Russell stated, in reply to Mr. pwood, that the Local Government Board have no reason doubt that the statement in the pamphlet entitled acts concerning Vaccination," sanctioned by his depart-nt, that "none of the nurses at any of the London small-x hospitals who have been duly revaccinated before ering on their duties have ever caught small-pox" is sub-ntially correct, although it might have been more rdedly expressed. From the report of the medical erintendent of the Fulham Hospital in March, 1882, it eared that at Fulham 42 out of a staff of 295 had had all-pox, at Stockwell 16 out of 340, and at Deptford 20 of 265.

Obituary.

REES HOPKINS, L.R.C.P., M.R.C.S.

Mr. Hopkins of Pontypridd, whose death occurred, in the rty-first year of his age, on the 1st ult., was born near antrissant. He commenced life as a veterinary surgeon at ontypridd, and this vocation he pursued for some years ith marked success. He afterwards commenced a course f professional study at the London Hospital, and in 1872 btained the diplomas of Member of the Royal College of urgeons and Licentiate of the Royal College of Physicians. e was medical officer to the Pontypridd Board of Health d the Rural Sanitary Authority, and held several other ublic appointments.

Medical News.

Royal College of Surgeons in Ireland.—At xaminations held on March 23rd and following days, the ndermentioned passed in Anatomy, Physiology, and ateria Medica:—

J. A. Coen, A. R. S. Craig, J. Duncan, J. D. O'D. Egan, R. Elliott, E. W. Hamilton, J. C. Hines, A. M. Hunt, E. B. Kennedy, A. D. Macleod, A. E. Murphy, V. Nash, H. F. C. Pilcher, J. A. Scully, A. F. Smith, P. Stephenson, W. Stritch, W. Swan, W. E. Waters, J. A. Whitty, D. T. Wylie.

Apothecaries' Hall.—The following gentlemen ssed their examination in the Science and Practice of Medi-ne, and received certificates to practise, on the 19th ult.:—

Mumford, Alfred Alexander, Manchester School of Medicine.

The following passed on the 26th ult.:—

Caskey, John Shaw, London Hospital.
Rhys, Watkin Llewellyn, Guy's Hospital.
Sutherland, John Russell, Glasgow University.
Walker, Thomas Greaves, London Hospital.

Dr. Smyth is a candidate for the vacant coronership North Kildare, and it is generally expected that he will returned.

A suggestion has been offered that the "Great Eastern" steamship should be utilised as a floating hospital at Suakim.

The salary of Dr. Cowen, medical officer of the Shadwell-road Workhouse, Islington Union, has been increased from £50 to £80 per annum.

Dr. G. P. O'Farrell of Boyle, and Dr. John Todd of Newtown Stewart, have been appointed medical inspectors under the Local Government Board, Ireland.

Spanish Universities.—The number of students who graduated in the Spanish Universities last year was 3598, including 94 doctors, in various faculties, 535 licentiates in law, and 703 licentiates in medicine and pharmacy.

The Manchester Hospital Sunday and Saturday Funds.—The amount paid into the bank up to the present time to the credit of Hospital Sunday Fund is £4745, and on account of Hospital Saturday, £3063, making a total of £7808.

Royal College of Surgeons.—Owing to the unprecedentedly large number of candidates for the "primary," or anatomical and physiological examination for the diploma of membership, amounting to upwards of 400, the library and museum of the College will be closed on Tuesday and Wednesday, the 7th and 8th inst.

On Tuesday last, Mr. Alderman Walmsley, M.R.C.S., of Salford, presided at a meeting of medical practitioners of Manchester, held at the old town hall, for the purpose of taking steps to found a new Medical Society in the city. A resolution was carried pledging the meeting to promote the object in view, if possible in harmony with the existing Medical Society.

Electric Light for Hospital Ships.—The Metropolitan Asylums Board has contracted with a Manchester firm for lighting by means of electricity the hospital ships and buildings at Long Reach. The plant will be in duplicate throughout, and a considerable saving will be effected in the annual cost of lighting by the substitution of electricity for oil.

Infectious Disease Hospital at Birkenhead.—On the afternoon of the 31st ult., the new ward which has been added to the hospital for the treatment of infectious diseases at the back of the Borough Hospital, Birkenhead, was formally opened by Mr. Frederick Smith, chairman of the Health Committee of the Corporation. The new ward has cost about £600.

University College Hospital.—The annual general meeting of the donors, governors, and subscribers of this institution was held on the 31st ult. The number of in-patients treated during the past year was 3152, as against 2849 in 1883, and of out-patients 33,743, as compared with 24,187. The annual subscriptions amounted to £2047, and the total reliable income to a little over £6000, whilst the necessary annual expenditure reaches £19,000.

The Royal Commission on the Housing of the Poor.—It is stated that arrangements have now been completed for the visit of the Royal Commission on the Housing of the Poor to Scotland. The visit is not one of inspection, but simply for the taking of evidence. The Commission will sit this day (Saturday), Monday, Tuesday, and Wednesday, and possibly for a few days longer. The Commission will probably visit Dublin during the Whitsuntide recess.

Lower Thames Valley Drainage.—The Local Government Board have addressed to the clerks of several constituent authorities comprised in the Lower Thames Valley Main Sewerage Board a letter, dated March 26th, stating the decision of the Local Government Board, after careful consideration of the report of their inspector (Mr. J. Thornhill Harrison, C.E.), on the recent inquiry held by him as to the proposal that certain of the districts now included in the Lower Thames Valley Main Sewerage Board should be separated from that district. The letter deals first with the application of the Heston and Isleworth Local Board, and states that the Board have determined, if the Local Board, after further consideration of the matter desire it, to issue a provisional order separating the districts of Heston and Isleworth from the main sewerage district. With regard to the separation of other districts as to which opposition was made, the Board are not prepared to issue a provisional order for the dissolution of the main sewerage district, or the separation of any constituent portion, with the exception of the two above-named districts. The letter also states that the Local Government Board are of opinion that before the Joint Board arrive at a final decision with regard to Sir J. Bazalgette's scheme (which, in the event of its adoption, should be carefully revised and perfected before it is submitted to the Board) they should fully consider whether it might not be practicable to adopt some other scheme which would provide for the disposal of the sewage outside the district of the Joint Board, and which would entail less cost.

Prize Subjects in Barcelona.—The following subjects have been chosen by the Royal Academy of Medicine and Surgery of Barcelona, for the annual prize dissertations this year:—1. Description of an Epidemic in Spain. 2. Best Method of preparing Cocaine. 3. Medical Topography of some District in Spain. 4. History and Present State of Hygienic Education in Spain.

Presentation.—On January 17th last a testimonial of 1000 rupees, which had been subscribed by the tea-planters and other residents of Kursung and the Terai (Bengal), with an address, was presented to Dr. A. B. Morris, who for the last ten years has practised as "planters' doctor" in that place, but the state of whose health is such that a change to a colder climate is considered necessary. Dr. Morris has gone to Auckland, New Zealand, where he hopes to found a practice.

Oxford Water-supply.—The informal committee appointed in June last to investigate this subject has submitted several samples to the analysis of Dr. Frankland and Dr. Tidy. Their reports were on the whole not unfavourable, but the water company has made the proposal to draw its supply from the Thames at King's Weir, some three miles above Oxford; and this plan, according to Professor Prestwich, seems to offer, apart from the question of cost, the best and most abundant supply of river water. He thinks "that with water drawn from this source, with proper settling reservoirs, and with the efficient filtering reservoirs now in course of construction, the water-supply of Oxford would in the future be as good and as abundant as could be ordinarily obtained from a river source, and that there would be little risk of a recurrence of those conditions to which there has been at times so much reason to object."

Royal College of Surgeons in Ireland.—Medical School.—The following prizes have been awarded at the termination of the winter session 1884-85:—Descriptive Anatomy: Senior Medal, Mr. Powell; First Class Certificates, Messrs. Bewley, Cummings, Strangman, and Nelson; Second Class Certificates, Messrs. Barter, Beamish, Ferguson, and Gourley. Practical Anatomy: Senior Medal, J. Lagan; First Class Certificates, Messrs. Matthews, Fenton, Hickey, O'Donohoe, Reid, Rossiter, Strangman, C. Woodwright, W. Woodwright, and Cook. Descriptive Anatomy: Junior Medals, Messrs. Gore and Johnston; First Class Certificates, Messrs. Banks, Ewing, Summers, and Jennings; Second Class Certificates, Messrs. Bruland, Lyons, Green, Molloy, McMunn, Clarke, Stewart, Harding, Finnegan, and Lee. Practical Anatomy: Junior Medals, Messrs. Byrne and Gourley; First Class Certificates, Messrs. Gore, Johnston, Marwood, Beamish, Cummings, O'Rafferty, Nelson, Lyons, Hanks, Barter, and Cremin.

Society for the Study and Cure of Inebriety.—The annual meeting of this Society will be held on Tuesday afternoon, the 7th inst., in the rooms of the Medical Society, Chandos-street, W., at four o'clock, when, after an address by the President, Dr. Norman Kerr, a paper will be read by Dr. T. D. Crother, Hartford, on "The Incipient Stages of Inebriety." The following have been elected officers for the year:—President: Dr. Norman Kerr. Vice-presidents: Sirs G. Burrows, W. Miller, G. H. Porter, E. Saunders, and Spencer Wells; Professors B. Foster, Macalister, McKendrick, and Maclagan; Surgeon-General Logie; Drs. J. S. Bristowe, Cameron, M.P., W. B. Carpenter, Farquharson, M.P., C. J. Hare, Geo. Harley, Wm. Ogle, B. W. Richardson, W. H. Walshe, and C. J. Wheelhouse. Treasurer: Dr. Drysdale. Hon. Secretary; Dr. Sturrock. Council: Surgeon-General C. R. Francis; Surgeons-Major Evatt and G. K. Roole; Drs. Balding, Barnes, Beverley, Bridgewater, Alfred Carpenter, J. Eastwood, Fitch, Gibson, Haynes, Hicks, Hurry, Lindsay, Reddie, Robertson, and Thomas.

The Premonitory Symptoms of Insanity.— Henry Sutherland read a paper on the above subje Brighton on March 24th, at the meeting of the So Eastern Branch of the British Medical Association. In paper it was shown by cases which had been for a long under observation, that various eccentric acts sometimes many (seven, twelve, fourteen) years before the actual out of insanity takes place. Hence the necessity for early prop lactic treatment in cases where the insane temperame strongly marked. The mental and bodily symptoms usu noticed in the early stages, and the indications for vari drugs, were also enumerated. The importance of approp moral and hygienic treatment was also insisted on. By tention to these details a second attack was often aver and if insanity had actually seized the patient, the dura of the disorder was shorter and the outlook more hop than would have been the case had treatment been neglect

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The La *before 9 o'clock on Thursday Morning at the latest.*

Davies, Sidney, M.A., M.B.Oxon., M.R.C.S. (of Cairo), has b appointed Médecin en Chef de la Police et de la Gendarm Egyptienne.

Dendy, Walter C., F.R.C.S.Eng., L.R.C.P., has been appo Assistant Medical Officer to the Workhouse of Birmingham Pa vice Williams, resigned.

Fraser, James A., L.R.C.P.Lond., M.R.C.S., has been appo Medical Officer to the Workhouse of the Romford Union, v Davey, resigned.

Garner, John Edward, M.D., C.M.Aber., has been reappo Medical Officer for the First District of the Preston Union.

McCracken, John, M.B., C.M.Glas., has been appointed Med Officer for the Coxwold District of the Easingwold Union, v Steven, resigned.

Matheson, Farquhar, M.B., C.M.Aber., has been appointed Honorar Aurist to the Royal Caledonian Asylum.

Murray, H. Montague, M.D., M.R.C.P., has been elected Honorar Physician to the Foundling Hospital, vice Dr. A. Tweedi deceased.

Smith, Henry Lionel, L.K.Q.C.P.I., L.R.C.S.I., has been appointe Medical Officer for the Overburg District of the Tewkesbury Unio vice Heslop, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Buzzard.—On the 28th ult., at Grosvenor-street, W., the wife Thomas Buzzard, M.D., of a daughter.

Fleck.—On the 27th ult., at Frogmoor Lodge, High Wycombe, Bu the wife of William Fleck, M.D., of a daughter.

Hett.—On the 27th ult., at Inverness-terrace, the wife of Geoff Hett, M.D., of a son.

Hoysted.—On the 31st ult., at 17, The Avenue, Colchester, the wife John Hoysted, Surgeon, Medical Staff, of a daughter.

Pedley.—On the 22nd ult., at 25, Burnley-road, Stockwell, S.W., t wife of R. Denison Pedley, L.D.S., M.R.C.S.Eng., of a daughter.

Stamper.—On the 28th ult., at Pembroke Dock, the wife of J. Fent Stamper, M.D., of a son.

MARRIAGES.

Harrisson—Freeborn.—On the 25th ult., at St. Mark's, Kenning John W. Harrisson, M.B., of The Friars, Sandwich, to Charlo E. Freeborn, second daughter of the late Dr. R. Fernandez Free of Oxford.

Whitelegge—Horsley.—On the 23rd ult., at St. Margare Westminster, Benjamin Arthur Whitelegge, M.D., to F Marian, elder daughter of J. C. Horsley, Esq., R.A., of High Kensington.

DEATHS.

Bridgman.—On the 19th ult., at Berkeley, Gloucestershire, Isaac Thomas Bridgman, Surgeon, aged 43.

Hastings.—On the 25th ult., at Mansfield-street, Portland-place, William Hastings, M.D., in his 56th year.

Pearse.—On the 28th ult., at Godfrey House, Cheltenham, Ge Pearse, M.D., late Director-General, Madras Medical and Honorary Physician to Her Majesty, aged 88.

Steil.—On the 25th ult., suddenly, at 110, Shepherd's-bush-road, W. Kensington-park, W., George Robert Steil, L.R.C.P., M.R.C. youngest son of James Steil, Esq., R.N., in his 35th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

ledical Diary for the ensuing Week.

Monday, April 6.

al London Ophthalmic Hospital, Moorfields.—Operations, 10.30 a.m., and each day at the same hour.

tal Westminster Ophthalmic Hospital.—Operations, 1.30 p.m., and each day at the same hour.

Mark's Hospital.—Operations, 2 p.m., and on Tuesdays at the same hour.

ipital for Women, Soho-square.—Operations, 2 p.m., and on Thursday at the same hour.

tropolitan Free Hospital.—Operations, 2 p.m.

al Orthopædic Hospital.—Operations, 2 p.m.

al Institution.—5 p.m. General Monthly Meeting.

Tuesday, April 7.

's Hospital.—Operations, 1.30 p.m., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 p.m.

Thomas's Hospital.—Ophthalmic Operations, 4 p.m.; Friday, 2 p.m.

cer Hospital, Brompton.—Operations, 2.30 p.m.; Saturday, 2.30 p.m.

stminster Hospital.—Operations, 2 p.m.

st London Hospital.—Operations, 2.30 p.m.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

SPONTANEOUS EVOLUTION.

To the Editor of The Lancet.

Sir,—The following case, which occurred at Guy's Hospital, is, I think, worth recording, as there are several points of interest in connexion with it.

C. H——, aged forty-three years, eleventh confinement. Labour commenced at 11 p.m. on the 8th. The extern was sent for, and on arrival found that the breech was presenting in the first position. Labour progressed rapidly, and the child was born alive at 11.40 p.m. It was then found that there was a second child in utero, but the presentation was not made out. At 12 p.m. (twenty minutes after the birth of the first child), the pains being absent, a drachm of the liquid extract of ergot was administered. The pains came on rapidly, and the right hand of the child was extended through the os. On this the extern sent for me. On arrival, I found that the child was born, the hand having descended still further, until both it and part of the forearm were outside the vulva. The pains now increased in severity. The right side and buttock of the child were born next, the right hand and forearm remaining outside the vulva; the head followed shortly afterwards, the left hand being extended over it. Artificial respiration was employed for about twelve minutes before the child breathed. Both were female children, the last born being exceedingly small.

In cases of spontaneous evolution like the foregoing it is extremely rare to find the child born alive. In this case several circumstances were favourable. (1) The first child had already enlarged the passages; (2) the woman had had ten children before; (3) the small size of the child. I weighed the child a month later, when it turned the scale at 3 lb. 12 oz.—Believe me, Sir, your obedient servant,

C. Y. Shuter, M.B.,
March 16th, 1885. Resident Obstetric, Guy's Hospital.

Dr. A. Harkin (Belfast).—Our correspondent will find a full account of the subject in the Comptes Rendus de la Société de Biologie, published by M. G. Masson, 120, Boulevard St. Germain, Paris.

Kentigern will no doubt obtain the information he desires from the registrar of the College.

EFFECTS OF HANDLING DYNAMITE.

To the Editor of The Lancet.

Sir,—I shall be glad if any information can be given how to avoid the unpleasant consequences of handling dynamite. Two officers of the Royal Engineers employed on the fortifications here have both complained of a bad headache lasting for about twenty-four hours after handling this substance, and also sore eyes. One of them made use of gloves, but a headache still resulted, apparently from the smell. I was not aware that nitro-glycerine acted through the medium of the skin or atmosphere, and no mention of this is made in Ringer's Therapeutics. I am, Sir, yours truly,

Aden, March 18th, 1885. E. Colson, Surgeon-Major.

DR. CHANDELON'S PROCESS FOR DETECTING STRYCHNINE.

BY this method the objects to be tested are chopped up very fine, and are mixed with an equal weight of gypsum entirely freed from water. After drying, the whole is pulverised, and thoroughly boiled with 90 per cent. alcohol, to which a little tartaric acid has been added. The alcohol is removed by distillation after filtration, the residue being taken up with boiling water, filtered so as to remove all fat, compressed to 1¼ to 1¾ cubic inch, and mixed with gypsum. After stiffening and pulverising, the mass is treated with chloroform in Soxblet's apparatus. The chloroform extract is brought to ¾ or 1 cubic inch, and there is added an equal volume of a saturated solution of oxalic acid in ether. The oxalate of strychnine becomes crystallised in needle-shaped forms, from which the strychnine can be isolated by ammonia. This method is said to have been successful in detecting minute quantities of strychnine, and to be likewise applicable to tests for brucine, narceine, papaverine, thebaine, aconitine, atropine, hyoscyamine, veratrine, nicotine, and coniine.

Mr. T. A. Buck, M.B.—We must refer our correspondent to some remarks on the subject in our issue of Sept. 27th, 1881.

"THE PHARMACY OF COCAINE."

To the Editor of THE LANCET.

SIR,—In an annotation on this subject in your issue of March 14th attention is drawn to a method for the preservation of solutions of cocaine by means of filtration through animal charcoal and subsequent addition of salicylic acid. I would point out to those who adopt this method the fact that animal charcoal removes alkaloid as well as impurities, and that filtration through this medium is calculated to seriously weaken the strength of cocaine solutions, especially those containing the smaller percentages of the salt. The preservation of these solutions is well effected by the use of salicylic acid alone, as recommended by Dr. Squibb of Brooklyn, employing a saturated solution of the acid in distilled water, to the extent of 50 per cent., or one-half, of the finished solution of cocaine—i.e., one-half water, and the other half solution of salicylic acid. The proportion of salicylic acid contained in the whole is then about 1 in 600, a quantity quite unobjectionable in use, but sufficient for the purposes of preservation. The alleged objection to its use on account of its extreme sensitiveness to traces of iron, and consequent difficulty in obtaining colourless solutions, we have not found realised in practice. We find no difficulty in sending out colourless solutions thus protected. The cocaine salts of our manufacture are not allowed to come in contact with iron at any stage of the process, glass and porcelain being alone employed. It was well pointed out by Mr. Symes in your issue of March 21st that an excess of acid destroys or renders latent the anæsthetic power of cocaine salts, as, so far as we are aware, this important fact had escaped record, although probably not observation. The addition of an acid to effect solution of the cocaine salt is entirely unnecessary if the neutral hydrochlorate be used. The alkaloid itself would be the most powerful, but its slight solubility (1 in about 700) almost precludes its use, although even in this high state of dilution it still has the characteristic benumbing effect on the tongue. The most important impurity in cocaine salts observed up to the present is the supposed inert alkaloid hygrine which exists in the leaves in variable proportion, and which, being considerably more soluble in water than cocaine, can be readily separated by prolonged washing and repeated reprecipitation of the cocaine, a process which also causes considerable diminution in the field of the latter, if means are not adopted for its subsequent recovery from the washings. Tests for the identification and purity of cocaine salts are greatly needed at the present time. For the first we know of no chemical tests available for the purpose. Its reactions are similar to those of other alkaloids; its anæsthetic effect on the tongue and other mucous surfaces is, however, sufficient for its identification. But this test is no guarantee of its purity; a small admixture of cocaine with other substances would produce its characteristic effect. Perhaps the most satisfactory test of purity is the amount of alkaloid precipitated by means of a solution of sodic carbonate from a weighed quantity of the cocaine salt. In the case of the neutral hydrochlorate this should amount, when moderately washed and dried until the weight is constant, to at least 89 per cent.

We are, Sir, yours faithfully,

High Cross, Tottenham, March 25th, 1885. TANNER & CO.

Mr. Hamilton Cartwright.—Would it not be better to bring the matter under the notice of the College of Surgeons?

Mr. Gem.—The report will appear in an early number.

"APPLICATION OF MIDWIFERY FORCEPS."

To the Editor of THE LANCET.

SIR,—As many letters have appeared in your journal on this subject, there is yet another method—namely, "with the patient directly on the back." This position obviates the necessity for drawing the patient over the edge of the bed, and can be more easily employed where the bedding is on the floor, as may occasionally be the case. In a manual on midwifery which has recently reached its fourth edition there is no allusion to this position. The manipulation of the superior blade is similar to the manner described by Mr. Lucas. As everybody appears to be conversant with Mr. Lucas's easy method, I would give him the satisfaction of knowing that it is new to me. I am, Sir, yours truly,

March 14th, 1885. BEAVER.

DISCOUNT IN DRUG BILLS.

A PETITION has been presented to the College of Pharmacists of Mi praying that any members who may be guilty of selling drugs to corporations, societies, or charitable establishments at any considerable reduction from the recognised price may be expelled. The Mi medical journal which reports this thinks that if it is carried into effect the College will have to expel a large number of its members—in fact, nearly all those who happen to supply public institutions.

A Country Doctor.—Our correspondent seems entirely right. But still think his case would be more complete with some personal remonstrance, preferably an interview.

M.B.Lond.—The letter has been already published in a contemporary

FLOATING DISPENSARIES FOR FISHERMEN.

To the Editor of THE LANCET.

SIR,—Through the kindness of a gentleman much interested in the North Sea Fishing Fleets, I had an opportunity last August of spending a fortnight on board one of the mission ships belonging to the Mission to Deep Sea Fishermen. What I then witnessed has induced me to bring the subject before the medical profession, in the hope that they will lend their aid towards alleviating the sufferings which smacksmen have to undergo, owing to the inefficient supply of medicines and medical appliances available in cases of illness. During the entire year a floating population of over 12,000 men and boys are at work in the North Sea, trawling for the fish with which Billingsgate and other markets are supplied. This great fleet is divided into eight minor fleets, each under the command of an "admiral," a sailor selected for his long experience and thorough technical knowledge, who, by means of flag signals by day and rockets at night, indicates the direction in which boats should sail, and the times for lowering and hauling up the trawls. The nature of the occupation in which these sailors are engaged is tiresome, harassing, and dangerous in the extreme. For eight weeks continuously each trawler is at work, a period of nine days being then allowed the crew to return home to recruit themselves and refit the smacks. Sailing with this fleet are some vessels which, besides engaging in trawling as the other vessels, are used as mission ships, and which also act as floating dispensaries. Being only four in number, they attach themselves to four of the minor fleets. A medicine chest (which has been pronounced by one of the sailors to be "one of the greatest blessings in the fleet") is kept on board each of these ships; but the natural want of knowledge on the part of the skippers, combined with the extreme difficulty of dispensing small doses of powerful medicines on board a small craft in heavy seas, greatly diminishes the advantages to be derived from such a provision. Under these circumstances, I propose to furnish one of the fleets with a supply of concentrated medicines such as are found most generally useful in dispensary practice, directions being given on each bottle as to the complaints for which such medicine is to be employed. Further, to supply a number of empty graduated eight-ounce bottles, so that, the doses being marked, the use of (which for obvious reasons would be useless) can be dispensed with. The concentration of the medicine being uniform (one drachm to the ounce), the only dispensing necessary would be to take one of the empty bottles and a sufficiency of the concentrated mixture to fill graduated ounce space, and then fill the bottle with water, directing the patient to take a marked dose three or four times a day, according to the urgency of the case, thus obviating the use of measure glasses, table- dessert-spoon, or other superfluities unknown on board a trawler. After thus providing for one fleet, seven others remain in need of some such provision. I would therefore earnestly appeal to the members of the profession, in the hope that they will contribute towards this object by either becoming responsible for the supply of medicines to some of the fleets, or by sending to the Secretary of the Mission to Deep Sea Fishermen—E. J. Mather, Esq., 31, New Bridge-street, Ludgate-circus, E.C. contributions towards providing for the expenses of such.

May I express a hope that through the columns of your journal you will aid the project by giving to it that publicity which it merits, and thus eliciting aid, as well as suggestions, as to the best manner of working the system. An early expression of the views of the profession would much oblige, as I am making arrangements for again visiting the fleet at an early date.—I am, Sir, yours faithfully,

HENRY J. PENNY, L.R.C.S., L.K. & Q.C.P.I.

Shenley, Barnet, Herts.

A TITLE FOR APOTHECARIES.

To the Editor of THE LANCET.

SIR,—Having observed your reply to "L.S.A." in last week's LANCET, in which you stated that the titles of "Doctor" and "Surgeon-Accoucheur" were, though not illegal, not "warranted" by the holders of the licence of the Apothecaries' Society, might I ask the favour of an opinion from you upon the following:—I am in the habit of describing myself, with the same qualification, as "Licentiate in Medicine." I cannot call myself "Apothecary," as I practise with the full sanction of the law as a physician, and I think it to a certain extent immoral to describe myself as "Doctor" and "Surgeon-Accoucheur." It appears to me and my friends an zxcellent and honourable way out of the difficulty.

I am, Sir, your obedient servant,

March 28th, 1885. LICENSED IN MEDICINE.

*** We see no objection to the description our correspondent gives of his qualification.—ED. L.

D. writes: —"I shall be grateful if any of my professional brethren will advise me what is best to do (educationally) with a youth, ged thirteen, not idiotic, but yet of such defective mental capacity hat it would be out of the question to send him to any ordinary school. He is not more difficult to control than such cases usually ave. He is the only child of a widow with very limited means."

RAPID SPONTANEOUS RESOLUTION OF A DEPRESSED FRACTURE OF THE PARIETAL BONE.

To the Editor of THE LANCET.

SIR,—The following case may prove interesting to some of your aders.

At 3 P.M. on the 4th inst. A. P——, a child one year old, was brought me, having fallen from its nurse's arms. The mother told me that at e time of the accident the child became semi-convulsed, and livid for few minutes, but did not lose consciousness. When I first saw it, enty minutes after the accident, it was perfectly sensible, and parently in its usual condition. On examination, the skin was rmal; there was no bruising or swelling, but an indentation, an inch ng, two-thirds of an inch broad, and one-third of an inch at its epest part, occupied the position of the left parietal eminence. With e exception of a little tenderness on manipulation of the part, the ild was in no way inconvenienced, and so little was the disturbance, d so marked the depression, that I at once put it down to a malformation previously existing, but only now discovered and attributed to the cident. The mother, however, assured me that such was not the case, d she was duly dismissed with the necessary instructions as to the eatment of the child. On the next morning I saw the child; it was uite well, and without a trace of the accident of the previous day. e mother informed me that she had noticed that by 7 P.M. on the day the mishap the skull had resumed its normal appearance. The case pears to me to be remarkable in the following points:—1. The slightss of the shock and the rapid recovery from it, and the immunity from mptoms co-existing with such a state of affairs. 2. The situation and aracter of the depression; its taking place at the strongest and most oroughly ossified part of the bone, this being completely inverted, to n apparently greater extent than it was formerly convex, and this without any evidence of detachment or crepitation. 3. The rapidity of solution—i.e., four hours—showing the pliant nature of the bone, more especially of the inner table of it, at this age, and the force exersed by the blood pressure, and the rhythmical pulsation of the brain.

I am, Sir, yours truly,

Kettering, March 16th, 1885. JOHN GRANT, M.B., C.M. Edin.

PERMANGANATE OF POTASH IN AMENORRHŒA.

To the Editor of THE LANCET.

SIR,—I reported a case of amenorrhœa successfully treated with ermanganate of potash pills in THE LANCET of Jan. 24th, 1885. Since hen another case has been brought to a successful issue by the same reatment. M. C——, aged eighteen years, came under my care on arch 1st. The patient was by occupation a dressmaker in Dublin, where she had been under medical care for some time; but her health did not improve, and she returned home and consulted me for the following:—Short cough; pain in the cardiac region and in the small of the ack; pulse 100 and weak; tongue and gums anæmic; appetite bad; oft-blowing, systolic murmur; and amenorrhœa, that had lasted for ix months. I at once ordered her a tonic of iron, strychnine, and digitalis, with plenty of nourishment, and at the end of a week, when her general health was greatly improved, I ordered permanganate of potash pills, one grain each, one pill to be taken with each meal. Six of these pills produced the desired effect, and the catamenia appeared in a regular manner four weeks afterwards. She is now taking a course of Bland's pills. The murmur has vanished, and she is going on in a most satisfactory way. I remain, Sir, faithfully yours,

CHARLES P. MURRAY, M.D.

Ashfield, Beau Parc, co. Meath, March 25th, 1885.

Northumbriensis.—The Local Government Board may, upon the application of the sanitary authority, dispense with so much of the regulation specified in its circular as requires that the medical officer of health, being duly registered, shall be qualified to practise both medicine and surgery.

"HYDROCHLORATE OF COCAINE."

To the Editor of THE LANCET.

SIR,—It matters little to your readers whether Mr. Fenwick or Mr. Abbott suggested camphor water as a menstruum in which to preserve hydrochlorate of cocaine as a solution. The credit, however, belongs to the latter (THE LANCET, Feb. 14th, p. 315). My object in writing was to bear testimony to the value of such a solution, and to caution the profession against trusting to Mr. Churchyard's assumption that a solution in distilled water which had become flocculent could be rendered as active as when freshly prepared by the treatment he mentioned. It is well known that a solution of cocaine hydrochlorate is rendered weaker by being passed through animal charcoal, and, as I have stated, the addition of acid further reduces its activity. A 4 per cent. solution which has become flocculent may still possess some activity, and this is best retained by passing it through a small piece of good filtering paper and adding a fragment of camphor to the filtrate.

I am, Sir, yours faithfully,

Liverpool, March 25th, 1885. CHARLES SYKES.

MEASLES IN GUERNSEY.

A CORRESPONDENT informs us that an epidemic of measles in Guernsey has been made the subject of a paper in the *Glasgow Medical Journal* by one of the medical men there. This paper, it is alleged, has been printed separately, and sent by its author to one of the patients of another medical man holding a high official position in the island. It is an essential part of our correspondent's communication that the epidemic was of an ordinary kind, characterised by no unusual complications calling for comment, and that the mortality was small. Our opinion is asked as to the action of the author in distributing his paper to the patients of other medical men. We think that such a use of professional writing is better avoided.

PALATABLE PREDIGESTED FOOD.

To the Editor of THE LANCET.

SIR,—In the leader upon Diet in the Febrile State in your issue of March 21st, alluding to the use of "already partially digested foods" for the purpose of avoiding the "fermentative changes from delayed intestinal digestion," you say that "unfortunately the preparations hitherto proposed for this purpose do not combine palatableness with efficiency," further expressing the opinion that an improvement in the former of the conditions named is much to be desired. Seeing what weight of authority every utterance of yours has, it were to be wished you had qualified the statement by the words "some" or "most of"; since I can bear testimony (unsolicited, I need not say, and without interest) that one firm of chemists at least has solved the problem of making an efficient article agreeable in smell and taste as well. Everyone knows how seldom in our homes and sick-rooms, at the hands of our cooks or nurses, we ever get a really good cup of coffee or cocoa; and I am quite sure that, the prejudice of a first trial once over, the almost instantly prepared cup of peptonised cocoa and milk or coffee and milk would be preferred as richer and more delicate in flavour to what we usually have placed before us. And if a preparation is really nicer to a healthy palate, efficiency being ensured, how much fitter must it be for the fastidious or perverted taste of the sick? I have for some time made use of the above preparations in typhoid fever, in tubercular affections of the abdominal organs, in acute and chronic albuminuria, and in diabetes mellitus, as well as in varying degrees of gastric irritation—in brief, in a wide range of cases where impaired digestion was only a secondary or even hardly appreciable factor, and in all with more or less benefit. In one case of diabetes, carefully watched for a month, and the urine daily examined, somewhat (I admit) to my surprise, the administration morning and evening of one breakfast-cup of the peptonised cocoa and milk did not increase the excretion of sugar; all the other conditions being as nearly as possible alike during that period, the gluten loaf not being used, and the only drugs administered being salicylic acid with a quarter of a grain of codeia.

I am, Sir, yours truly,

March 25th, 1885. F. ARNOLD LEES, M.R.C.S. &c.

⁂ *Both cocoa and coffee undoubtedly disguise the peculiar flavour of peptonised food better than anything else; still, even thus prepared, peptonised preparations have, to our taste, in a slight degree the peculiar flavour, which to some persons is extremely unpleasant, of peptones, though in this respect they are superior to most dietetic articles of this kind.*—ED. L.

M.R.C.S.—We do not think it advisable to extend to such cases further publicity. The attention of the bodies whose qualifications the offenders hold should be called to the way in which their diplomas are disparaged.

"CARBOLIC OIL A REMEDY AGAINST MOSQUITOES."

To the Editor of THE LANCET.

SIR,—The unfortunately too frequent differences amongst doctors when they do ventilate their opinions may, so far as the above matter is concerned, be very easily explained. The application of carbolic acid and oil, in the proportion of 1 to 10 or 15, is for a time perfectly successful in keeping off mosquitoes; but the carbolic acid evaporates so rapidly that a renewal has to be made every half-hour or thereabouts. So far as my experience goes, there is no place where the sting of the mosquito is so venomous as on the banks of rivers and lakes, and after exposure in such places I have known men to be laid up and disfigured for weeks. By using the oil, and repeating its use every half hour or so, I have fished where all other fishers were half smothered with mosquito muslin wrapped round them—and in the tropics this is very heat-producing, even if effectual in keeping out the "wily mosquito"—with perfect impunity, and the only difficulty I had was to keep it out of my eyes, as it produces smart pain if it touches the conjunctiva. Put a bottle of freshly mixed acid and oil in your pocket, and apply it at frequent intervals on hands, neck, and face, and you may defy mosquitoes, gnats, *et hoc genus omne.* My experience includes the East and West coasts of Africa, the East and West Indies, North America, and the Arctic. The Arctic black gnat in summer is as annoying as any "punkah mosquito." Before I used carbolic oil I employed creasote and oil, and a mixture of it used to be sold at least a quarter of a century ago by the fishing tackle folk in the land of the "Blue Noses;" indeed, it was my experience there which led me to substitute the carbolic acid for the creasote. I am, Sir, yours faithfully,

March 23th, 1885.

AN OLD SALT.

HOMES FOR MENTAL CONVALESCENTS.

To the Editor of The Lancet.

Sir,—Amongst the many valuable institutions of the day is there not one greatly needed—convalescent homes for our pauper lunatic asylums? All medical men who superintend these asylums would, I believe, agree on the value of such convalescent homes, not only as preparing patients for return home when rallying, but as more likely to lead to recovery than at present is the case. And what a boon the change would be to those whose nervous system has been shattered!

> "The very air, the sun, the skies,
> Would seem like opening paradise."

And for those preparing for return to cottage homes, &c., would not a large farmhouse or some such home, with simplest furniture, but with possibly garden and poultry, be sufficient, and better than grander buildings? Such convalescent homes might be attainable without great outlay, as the patients would still be paid for, as at the asylums?

I am, Sir, yours faithfully,

March 30th, 1885. H. B.

*** Our correspondent will find, on referring to our issue of May 17th, 1884, a *letter from the Rev. H. Hawkins, Chaplain of Colney Hatch Asylum,* calling attention to the want of convalescent homes "to supplement the recovery of patients discharged from asylums for the insane." As we then pointed out, the need of such institutions has long been recognised.—Ed. L.

TWIN BIRTH IN WHICH ONE CHILD WAS AN ANENCEPHALUS.

To the Editor of The Lancet.

Sir,—On March 15th I delivered Mrs. B——, in her sixth confinement, of a living female child, and on perceiving two cords I examined, expecting to find a normal vertex presenting, as in the first case, instead of which I felt the cranial bones loosely covered with skin. Uterine action setting in, a fœtus was expelled, smaller than the first, perfectly developed as regards bodily conformation apparently. On section of the scalp not a vestige of brain tissue was to be seen, merely the membranes thickened and congested. The husband informed me that his wife received a severe shock seven months since at the sea-side, when she saw a hideous-looking man, and he states that the physiognomy of the encephalon corresponded exactly with the individual she then saw, it having the same depressed bridge of nose, &c. I should add that there was only one placenta. I am, Sir, yours faithfully,

Hollywood-road, S.W., March 24th, 1885. Wm. J. Heddy, M.R.C.S.

Mr. C. C. Burman (Belford, Northumberland).—The inquiries addressed to us are matters requiring careful investigation. We have found the paroxysms to be almost always more frequent at night, whether the patient sleep or not. In the early part of the course of the complaint the paroxysms frequently occur when the child is put to bed and at about 2 or 3 A.M. Profound or light sleep, in our experience, exercises but little influence; when sound sleep is possible, the attack is generally slight. Any striking alterations in the patient's environment may induce an attack.

PAIN IN THE FOOT AFTER HEMIPLEGIA.

To the Editor of The Lancet.

Sir,—Will you allow me to ask some of your readers if they can help me to relieve severe pain occurring paroxysmally in the foot after hemiplegia, accompanied with tingling and numbness. Ointments of aconite and belladonna have exasperated it. The patient *objects to hypodermic* injections. Would it be wise to try the constant current? I have failed so often that I do not wish to resort to this without previously having the benefit of other experience than my own.—Yours faithfully,

March 30th, 1885. H. G. D.

TRANSMISSION AND TRANSMUTATION OF DISEASE.

To the Editor of The Lancet.

Sir,—I shall be greatly obliged *if any members of* the profession furnish me from their own experience any of the following:—1. A tree showing the transmission of phthisis, gout, or rheumatism, (if possible) three generations and one or more collateral branches family. 2. Any instances of the transmutation by heredity of diseases—e.g., epilepsy, hysteria, alcoholism, &c., into insanity, or *versâ.* 3. Any good instances of the hereditary transmission of diseases. I am, Sir, yours faithfully,

Belfast, March 28th, 1885. James A. Lindsay, M.A., M.D.

The Publisher cannot hold himself responsible for the return of monials, &c., sent to the office in reply to advertisements; copies should be forwarded.

Notice.—Advertisers are requested to observe that it is contrary the Postal Regulations to receive at Post-offices letters addressed initials only.

An original and novel feature of "The Lancet General Advertiser" is a special Index to Advertisements on page 2, which not only ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to Advertisements appearing in The Lancet.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all oth Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lumleian Lectures
ON
POINTS IN THE NATURAL HISTORY OF PRIMITIVE DRY PLEURISIES.

Delivered before the Royal College of Physicians,

By SIR ANDREW CLARK, Bart., M.D.,
FELLOW OF THE COLLEGE.

LECTURE III.

Mr. President and Gentlemen,—In the last lecture I arranged, for the sake of convenience, the pathological changes in the lung resulting from primitive dry pleurisies under four heads, and I intimated that for each of these there was to be found a corresponding clinical state or autonomy. I proceed now to consider these clinical states, to describe their chief characteristic signs, and to show in what manner they may be distinguished from other states resembling them, but having a different meaning and importance. The former, for descriptive purposes, I shall name the neoplastic pleural membrane state, the fibroid lung state, the bronchiectatic state, and the phthisical fibroid lung state.

And first of all, concerning the neogenetic pleural membrane state. The patient may have the aspect of health, and experience no subjective indications of the presence of disease. If any exist, they will be limited to uneasiness or pain in the affected side, an occasional dry cough, feverishness, and general malaise. On rare occasions the patient may be conscious of the existence of pleural friction. The physical signs are a slight decrease, with some irregularity, of the thoracic movements of the affected side, some diminution of the tactile vocal fremitus,[1] just notable but unequal dulness on percussion, a shifting, rubbing or grating friction, enfeebled breath sounds, and an altered vocal resonance. In some cases, instead of pleural friction there may be heard crepitation, crackling, or clicking; and we shall know from the superficial characters of these sounds, from their resistance to respiratory efforts, and from their association with gratings or rubbings that they are of pleural origin. Having thus before us a dry pleurisy, we have to determine if it is a primitive or secondary affection. If there are signs of disease in the corresponding or in the opposite lung, it is probable that the pleurisy is secondary; and if without such signs there is grave constitutional disorder, it is equally probable that the pleural inflammation has arisen out of some pre-existing malady; and this pre-existing malady may exercise its causal influence either through some local growth, such as tubercle, lying beyond the range of physical detection, or through some constitutional state, such as adenoma or syphilis. On the other hand, if there exist no signs of local disease, and no serious symptoms of constitutional disturbance, it is presumable that the case is one of primitive dry pleurisy. This affection may arise from mechanical injury, or from cold, and it may be a local expression of such non-malignant constitutional disorders as rheumatism and gout.

The future course of a case of primitive dry pleurisy depends upon causes seldom visible or calculable, and is therefore absolutely uncertain. The signs of the malady may subside in a few weeks, or they may continue for months, or they may come and go for two or three years, and then either entirely disappear or invade the lung. Sometimes after a variable duration the dry stage issues in serous effusion, which pursues its ordinary course, and ends eventually in a thickened pleura and a contracted lung. In one case seen with Dr. Sedgwick, and in another seen with Dr. Warrington, it appeared as if the structural elements of an old adventitious pleural membrane developed through metaplastic processes into malignant fibrous growths. This result, however, must be infinitely rare; and when the health of the patient is good, and he can be placed under the conditions most favourable to the organism, clinical experience will warrant the expectation of complete recovery. Nevertheless, it occasionally happens, in spite of apparent good health and skilful care, that the inflammatory process invades the lung and brings about therein a more or less extended fibroid induration. This fibroid lung state is of frequent occurrence, and from the mistakes liable to be made concerning it, and the course which it commonly follows, it is a subject of great importance as well as of great interest. It certainly demands, and will certainly repay, an extended and a critical study. We have, in the first place, to make sure that we are dealing with a fibroid lung state. What seems to be a simple fibroid induration[2] may be something quite different; or it may be that and something more. It may be essentially a tubercular consolidation with an unusually large amount of secondary fibroid growth; it may be a chronic caseous pneumonia; it may be a pleuritic effusion; it may be a malignant growth; and it might be several other things which for practical purposes need not now be considered. If the case has been followed from the beginning, no serious difficulties of diagnosis will be encountered; but if, as usually happens, the patient is not seen until the pulmonary consolidation is advanced, the greatest care will be required to avoid falling into serious error, and to succeed in framing a correct judgment. If there are no serious symptoms of constitutional distress; if there is no elevation of temperature and no hurry of circulation; if flesh, colour, and strength are little, if at all, affected; if in the consolidated lung there are no signs of disintegration, and in its fellow lung no indications of advancing and spreading disease,—the question of tuberculosis may be settled in the negative. And it may be so settled conclusively if after repeated examination of any sputum which may be ejected no tubercular bacilli are found therein.

With respect to caseous consolidations, they are of two sorts: one which is tubercular, and one which is not. From simple fibroid induration, the former may be distinguished by the presence of tubercular bacilli in the sputum. And as to the latter, if there is no history of a feverish illness; if there is no elevation of temperature, or quickness of the pulse, or cough, or expectoration; if there is material retraction of chest, with diminution of tactile vocal fremitus; if no râles are heard within or around the consolidated lung; and if the vocal resonance is either diminished or not increased,—then the hypothesis of any sort of caseous consolidation must be abandoned. Furthermore, if the patient has no cachectic appearance; if there are no irregular retractions of chest, no depression of shoulder and nipple, no pushing outwards of the lower part of the scapula; if, with extensive consolidation, there are no pains or signs of pressure, no extension of dulness beyond the normal limits of the lung, no displacement of heart, no distress of breathing with blood-stained expectoration, no rapidity of pulse without notable elevation of temperature,—it may be said with all but absolute certainty that a malignant growth is not the cause of the consolidation.

But in fibroid lung the condition which by far the most frequently gives rise to mistakes in diagnosis and errors in practice is pleural effusion. To mistake an ordinary and considerable serous effusion for a fibroid lung can happen only from want of competence or want of care. The fixed and rounded side; the tumid or even bulging intercostal spaces; the dulness, varying with position; the feeble breath sounds, except near the spine, where they are bronchial; the diminished resonances; the displaced organs,—if duly examined and considered forbid peremptorily every interpretation but one. Happily, however, the danger of mistake does not lie in this, but in an opposite direction; it lies in supposing that a solid fibroid lung is a fluid effusion. And here it must be confessed that, when the effusion is moderate in quantity and of long-standing, when the dulness does not vary with position and there is no displacement of organs, when the signs of local disease have descended from an acute pleurisy and there is no account of pulmonary disease, the difficulties of diagnosis are great and not always, without exploratory operations, overcome. For in both conditions, in the moderate fluid effusion and in the indurated lung, there are to be found diminished respiratory movements of the affected side, toneless dulness on percussion, decreased tactile vocal fremitus, feeble, hollow, or suppressed respiratory murmurs, and lowered as well as altered vocal resonances. Nor, indeed, do exploratory operations always overcome these difficulties. Fluid may be present, and none be withdrawn by the needle. It may not penetrate the thick and hard pleura; it may carry the membrane before it, or it may become blocked by débris. But, notwithstanding this close similarity of physical signs between affections so widely different, grounds of distinction between them, if narrowly sought for, may be in most cases discovered. In the first place, the continuous history of an illness beginning with an unmistakable pleurisy, and passing straight into a basic dulness of doubtful nature, points strongly, but not necessarily, to fluid effusion; not necessarily because a fibroid induration, although it sometimes originates and advances unattended by inflammatory or other local or general symptoms, occasionally arises in, or immediately follows, a pleural inflammation; or is begotten by substitution out of an unabsorbed pneumonic exudation. In the second place, if we are dealing with a fluid, and especially if that fluid be purulent, there will probably be present some degree of fever, and almost certainly some acceleration of pulse; in a fibroid consolidation there need be neither the one nor the other. In the third place, if fluid be present and confined to a portion of the pleural sac, the side, although generally flattened or retracted, will be swollen over the part where the fluid is collected; the intercostal spaces will be effaced or more or less bulged; the diminution of the tactile vocal fremitus will be uniform; the dulness on percussion will be more diminished in volume, raised in pitch, shortened in duration, and lessened in resistance than when dealing with a fibroid induration; the breath sounds will be feeble or suppressed; there will be no râles; and the vocal resonance lowered and altered may be ægophonic. In the fourth place, we may conclude that we are dealing with a solid lung if, with the signs already described, we find that the affected side is everywhere, and especially irregularly, contracted, that the intercostal spaces are deepened, that the dulness is accompanied by great hardening and resistance, that the tactile vocal fremitus, much diminished, is unequal throughout the dull region; that there is rubbing or creaking; that there are râles of any description, superficial or deep; that the vocal resonance, increased or diminished, and varying at different parts, has a metallic quality; and that there is some, however slight, displacement of organs to the affected side. Having thus cleared away the various sources of error in diagnosis, and having made sure that we are dealing with a fibroid lung, I proceed to set forth its clinical characters and course.

---

[1] I do not forget that Dr. Walshe has spoken otherwise; and it is only after careful investigations, often repeated, that I venture to differ from one of the most accomplished auscultators of our time.

[2] Or, to use another terminology, an interstitial pneumonic consolidation, cirrhosis, sclerosis, or iron-grey induration.

I shall, in the first place, consider the local physical signs, and in the second, the constitutional state. Among many descriptions drawn from life of the physical signs of fibroid lung I possess in particular two, one of which was written in conjunction with Dr. Pollock in 1868, and one with Dr. Douglas Powell in 1885. As concrete examples will strengthen the general description, and as the authority of those justly distinguished physicians will stamp with accuracy the relation of the physical signs in the cases examined, I herewith reproduce them

Dr. Pollock's case, examined with Dr. Andrew Clark, October 21st, 1868.—A farm labourer, well nourished, rosy, and of healthy aspect, fifty-seven years of age, and of regular and temperate habits, complains of occasional cough, slight morning expectoration, and breathlessness on exertion. His father died at sixty from renal disease; his mother, aged eighty-six, is alive and well; two sisters are living and in good health; two brothers and sisters died from causes unknown. In 1860 the patient had trouble, presumed to be pleuritic, in his left side, and after some weeks got well. In February, 1868, eight months before this examination, the patient caught cold, shivered, felt sharp pain in the left side, became feverish, had a little cough, and was confined to bed; had night sweats some time in March; in April or May was well. The digestive organs are in fair condition; the urine is abundant, sedimentary, of low density, and contains a considerable amount of albumen. The left side of the chest is flattened from the clavicle to near the nipple, in the lower part of the axillary region, and about the posterior base. The impulse of the heart is felt immediately under the left nipple, and its action, unaccompanied by murmurs, is normal; the pulse is about 80.

Examination of left side.—Above the clavicle the percussion note is normal; from second rib to anterior base, except near the sternum, there is absolute dulness, which nowhere passes the median line. In the lower half of the axillary region, and posteriorly from the spine of the scapula to the base of the lung, there is marked and increasing dulness; in front, from summit to nipple, in the upper half of the axillary region, and posteriorly in the supra-spinous fossa, and for a little way below the spine of the scapula, the tactile vocal fremitus is increased; elsewhere it is in different degrees at different parts demolished. Upon auscultation the following signs are elicited. In the supra-clavicular region there is normal vesicular breathing, but an occasional wheeze is heard at the close of inspiration, and the expiration is prolonged. From the clavicle to the second rib the inspiration is rustling; the expiration prolonged and blowing. Between the second rib and the nipple the respiration is bronchial and the vocal resonance is altered and increased. From the nipple to the anterior base the respiratory sounds and the vocal resonance are suppressed; only a faint creaking, crackling, or rumbling is heard. In the upper part of the axilla there are heard pleural creaking, bronchial breathing, and a modified bronchophony; in the lower part all sounds are suppressed. In the supra-spinous fossa the respiratory sounds are loud, harsh, and accompanied by crepitation, which, on coughing, becomes a crackle. There is no increase of vocal resonance. From the spine of the scapula, where they are weak and hollow, the respiratory sounds become fainter towards the base, and are there wholly suppressed. In no part of the right lung can any sign of disease be discovered. In 1878 the patient was reported to be in the same condition; but since then he has not been seen.

Dr. Douglas Powell's case, examined with Sir Andrew Clark on Jan. 7th, 1885.—The patient is a dark, stout, florid, healthy-looking man of fifty-four, and has no complaint except that he is breathless on exertion, and that he gets a little cough and expectoration in cold and damp weather. He has been slowly gaining flesh and strength for the last six years. In 1863 or 1864 patient had some serious trouble in his left side, and was ill for seven weeks. In 1866 he had a fresh illness with pains in his left side, and "a feeling as if there were two holes in his lung when he took deep breaths." Was first seen in November, 1867, by Dr. Andrew Clark, who reported the case to be one of chronic dry pleurisy, with secondary fibroid induration of the lung. About this time he was for six months an inmate of the Brompton Hospital, where he was repeatedly examined by Dr. Douglas Powell. The left side of the thorax is flattened and irregularly retracted, rises imperfectly and unequally on inspiration, and measures on the level of the nipple sixteen inches and a half, being one inch and a half less than the measurement of the opposite side at the same place. The left shoulder is depressed and angular; the left nipple corresponds to the fifth rib. The lower part of the axillary region is protuberant, and the upper retracted. The inferior angle of the scapula juts outwards from the ribs. The impulse of the heart is felt under the left nipple, and its action is slow and normal; the pulse is full, soft, and compressible. The percussion note, slightly tubular in the supra-clavicular space, and normal just below the clavicle, becomes increasingly dull to the base, where the dulness is absolute. In the axillary region there is dulness throughout, slight above, moderate in the middle, absolute at the base. Posteriorly dulness begins below the spine of the scapula, and increases to the base. The tactile vocal fremitus, normal at the summit and increased at the middle of the axillary region, is everywhere else either greatly diminished or entirely suppressed. About the summit of the lung the respiratory sounds are harsh, but of the vesicular type, and the expiration is prolonged; there are, however, no râles. About the middle of the axilla there are heard superficial creaking or rubbing, with occasional coarse crepitation and dry rhonchi, elsewhere the respiratory sounds are feeble, hollow, distant. The vocal resonance, loud in the supra-clavicular region and just below the clavicle, is bronchophonic in the middle and upper part of the axilla; at the base it is suppressed, and in other parts diminished. The right side of the thorax, full and rounded, rises fully on inspiration, and yields to examination no evidence of disease. The digestive organs are in excellent order. The urine, with less than an average discharge, has a specific gravity of 1014, is acid, clear, and contains no trace of albumen or of sugar.[3]

From these two cases, average specimens of their class, a tolerably complete account may be obtained of the physical signs characteristic of the fibroid lung, and from the records of Dr. Douglas Powell's case one will now see how one may reasonably demur to the propriety of designating by the term chronic interstitial pneumonia a state of lung which has been quiescent for years, develops no general symptoms, and is compatible with more than average health. In these circumstances the terms sclerosis or fibroid ought, I think, to be preferred, inasmuch as they indicate with sufficient accuracy the physical characters of the pathological change, involve no hypothesis, and may, whilst hypotheses change, remain unchanged.

---

[3] Since the delivery of this lecture Dr. Douglas Powell has reminded me that on more than one occasion the urine of this patient has been slightly albuminous.

The local physical signs of pulmonary fibroid induration of moderate extent may be now formally enumerated, and they are as follows. The disease is commonly unilateral; the affected side is irregularly flattened or retracted; the shoulder is depressed, the lower angle of the scapula is tilted outwards, the spine is sometimes a little twisted, and the respiratory movements, especially the movement of expansion, are defective and irregular. The tactile vocal fremitus is diminished; there is more or less dulness on percussion; pleural rustlings, crepitations, cracklings, creakings or frictions are always at some time audible; the respiratory sounds are usually feeble, hollow, distant; from time to time there are crepitations which are often of a metallic quality, with moist or dry mucous rhonchi.

Such are the physical signs in favourable cases ,of fibroid lung, where the elasticity of the parenchyma is but moderately diminished and its nutritive conditions are not seriously disturbed. When, however, the base of the lung, surrounded and invaded by indurated lymph, has lost a great part of its elasticity, and the bronchial mucosa, stimulated by undue supplies of altered blood, secretes a more or less viscid mucus which cannot be expelled, bubbling rhonchi of metallic quality are heard in the affected region, and there arise recurring paroxysms of cough, which succeed, only by the help of retching, in emptying the bronchial tubes. Although this condition invades the comfort of the patient, it does not, unless greatly aggravated, seriously injure the health or obviously limit the duration of life. But when the lung becomes more and more rigid, and the bronchial tubes fill more easily with secretion, which is with increasing difficulty expectorated, the patient begins to suffer, and through secondary congestions, consolidations, emphysemas, and perhaps bronchial dilatations, both health and life are placed in peril. The constitutional symptoms accompanying fibroid lung vary according to the state of the induration. When this is not advanced enough to destroy the pulmonary elasticity, when the bronchial secretion is not in excess of what can be easily expectorated, and when the patient is kept under favourable physiological conditions, the general health is little if at all affected. It is true that he becomes breathless on exertion, that his general power of resistance to disturbing causes is lowered, and that from small provocation he falls into bronchial gastric or vesical catarrhs. Nevertheless, with just guidance and loyal obedience to it the patient may continue beyond the average duration of life to live and work. On the other hand, when the induration has destroyed the elasticity of the pulmonary parenchyma and the bronchi are filled for hours with sputa, which cannot be discharged, and perhaps undergo septic change, the constitution suffers; sometimes there is gastric, hepatic, and enteric catarrh; sometimes the urine falls in density and becomes more decidedly albuminous; sometimes the face and neck become swollen and the veins of the affected side enlarged; sometimes the feet become œdematous; and always, even with increased frequency of pulse, the temperature falls below the normal standard. But even in these conditions, with his comfort invaded and his capacity for work narrowed, the patient may return to the favourable stage of his malady, or without doing so may reach the longest term of life. The albuminous urine existing in the great majority of cases of fibroid lung seems to be of small importance in its earlier stages. But in its later and more unfavourable stages, when the bronchi are almost always loaded, and the lung becomes increasingly hard and congested, and the circulation is hurried and feeble, and the skin cold and harsh and dry, the condition of the kidneys becomes greatly aggravated, and at last puts an end to life. Indeed, in the greater number of cases, it is the renal and not the pulmonary affection which puts an end to life.

Proceeding now to the bronchiectatic lung state, I have to observe that its clinical characters have been elsewhere so admirably and exhaustively described that I do not feel justified in occupying the time of the College by giving another description, which I could not execute so well, and to which I could add so little. Nevertheless, I desire to notice some points in the clinical history of bronchiectasis, either because they have not been dwelt upon before, or because they have been inadequately or erroneously described. In the first place, the general condition of the bronchiectatic patient differs materially from the subject of tubercular phthisis on the one hand, and of fibroid lung on the other. Pale or cyanosed, for the most part thin and stooping, distressed by paroxysms of cough and drained by discharges of purulent and sometimes fetid expectoration, the subject of bronchiectasis displays a combination of mental and bodily engergy not to be met with in any other disease. In the second place, whilst in fibroid lung the disease is for the most part unilateral and in tuberculosis bilateral, in bronchiectasis both forms occur in nearly equal numbers. In the third place, whilst bronchiectasis resembles fibroid (for which it could not well be mistaken) in temperature, circulation, forms of cough, kinds of expectoration, conditions of breathing, absence of malaise, and slowness of general progress, it differs in almost all these points from tubercular phthisis, with which it is frequently confused and has nevertheless little in common. In the fourth place, whilst the excavations of fibroid occur at any part of the lung and the excavations of tubercular disease at its summit, and whilst the excavations of both, when they are multiple, appear in groups without definite form or order, the dilatations of bronchial tubes, found more frequently at first in the middle and lower than in the upper lobes, are arranged in order along the bronchial ramifications. In the fifth place, whilst the excavations of fibroid and tubercular disease arise in the midst of consolidations, the bronchial dilatations have no necessary relations to them, and, although commonly surrounded by fibroid induration, may be often found in the midst of apparently unaltered lung. In the sixth place, although bronchial dilatations may be unsurrounded by peribronchial thickenings, or by pulmonary induration, chronic pleuritic neoplastic membranes are never absent. In the seventh place, when several cylindrically dilated bronchi lie near to each other, the physical signs are sometimes such as to suggest the existence of a large cavity with rigid walls; but a careful and often repeated study of those signs will prove that they vary with the amount and time of the expectoration, and that sometimes the signs of a cavity are often wanting, and that at other times they are present only in isolated parts. In the eighth place, in opposition to Traube and others, I contend that the sputum in bronchiectasis, similar in characters to that of advanced and regressive fibroid, frequently contains fragments of elastic tissue in two forms: first, in the form of bands, consisting of fibres running in straight lines parallel to each other; and, secondly, in the form of elastic areolæ and thickened intersecting trabeculæ. The former are exfoliated from the bronchial mucosa; the latter come from the pulmonary alveoli disintegrated by ulceration proceeding outwards from the bronchial dilatations. In the ninth place, the sputum in uncomplicated cases of bronchiectasis, accompanied or unaccompanied by fibroid indurations and excavations, does not, as far as my present experience extends, contain tubercular bacilli. In the tenth place, the only certain means of distinguishing a tubercular from a bronchiectatic cavity, or of knowing when a tubercular has supervened upon a fibroid or bronchiectatic process, is the presence in the sputum of tubercular bacilli.

Leaving now the bronchietatic lung state, I proceed to consider the chief points in the clinical history of the phthisical fibroid lung. As before, I will discuss, first, the local and physical signs, and thereafter, the constitutional or general symptoms. The physical signs of the phthisical fibroid lung are the same as those of the simple fibroid lung, with certain alterations and additions. The disease is for the most part unilateral; and when we inspect the chest, we observe the same flattening or retraction of the affected side, the same depression of the shoulder and nipple, the same leaning of the body to the affected side, the same approximation of the ribs and hollowing of the intercostal spaces, the same displacement of the cardiac impulse and throbbing at the root of the pulmonary artery,[4] the same projection of the lower angle of the scapula and twisting of the spine, the same restricted movements of inspiration, and the same rounded fulness and compensatory expansion of the unaffected side. By palpation and percussion we elicit results resembling those elicited by examination of the fibroid lung: diminution in varying degrees of tactile vocal fremitus, sometimes friction fremitus, and dulness on percussion, seldom over the upper, usually over the lower lobes, and most frequently at the posterior base. Upon auscultation we hear over the summit a harsh and jerking respiratory murmur, prolonged expiration, perhaps some medium crepitation or dry rhonchus, and increased vocal resonance. Over the dull regions there will be heard feeble breath sounds, coarse crepitations, and bubbling rhonchi, usually metallic in character; at some parts the vocal resonance will be diminished, and at others increased. At one or two spots in the base or middle of the lung, very rarely at its summit, there will be found a tubular percussion note, increased fremitus, cavernous breathing, bubbling or smaller gurgling râles, and piercing bronchophonic voice resonance. Throughout the lung opposite the affected one the respiratory murmur, penetrating everywhere, will be found loud, harsh, and accompanied by a few rhonchi or by scattered moist crepitations, which come and go. The patient has paroxysms of cough, making the face swollen and livid, and ending sometimes in dry retching, sometimes in the expulsion of several ounces of expectoration. This expectoration, sometimes gelatinous or muco-purulent, sometimes in discrete opaque masses like softened cheese, sometimes watery, sanguinolent, or fetid, contains in a mucoid or granular matrix pus-globules, granule-cells, blood-discs, epithelial cells, bands and areolæ of elastic tissue, and the débris of decaying structures swarming with micrococci. The breathing, quiet when at rest, becomes, on moving about or on coughing, shallow, laboured, and quick. The heart, drawn to the affected side, may be acting vigorously and with moderate frequency; there will be probably a systolic bruit in the pulmonary area; the pulse will be of moderate volume, and the superficial cervical veins will be distended. If the disease is much advanced, the face and neck will be swollen, and the integument over the side of the affected lung may become œdematous; the pulse will increase in frequency and diminish in volume, and the extremities will become cold and damp. The digestive organs are more or less deranged through hepatic and gastro-enteric catarrh; the liver is enlarged, there are often hæmorrhoids, and the bowels are confined. Almost invariably the urine falls in density and contains albumen; and this condition of the renal secretion is one of the features which, with others to be mentioned, make so striking the difference between fibroid and tubercular phthisis. The patient is often fairly nourished, sometimes corpulent, and, unless there is much bronchiectatic disease, seldom thin. In a few cases he becomes cachectic-looking and anasarcous. The nervous system, except towards the close of the disease, is seldom seriously disturbed. Only one symptom occurs sufficiently often to be regarded as characteristic; this is pain about the base of the affected lung. Present in many cases, sometimes slight, sometimes severe, occasionally occurring in paroxysms which play around the attachments of the diaphragm and pass downwards into the abdominal walls, this pain, regarded as a neuralgia, is considered by the patient to be the essential part of his malady, and causes him, in fact, his chief if not sole complaint.

---

[4] This throbbing at the root of the pulmonary artery is sometimes mistaken for the systolic impulse of the left auricle.

With such serious signs of disease, and with such an assemblage of symptoms depending thereon, it might well be thought that the patient was in constant suffering and in imminent peril; and yet, strange to say, it is sometimes quite otherwise. The symptoms which seem the most distressing cause him either little suffering or suffering which is immediately forgotten; and soon after a paroxysm of coughing, in which death from mechanical violence or suffocation or exhaustion seems inevitable, the patient may be found full of business, sparkling with humour, and confident of life. Here is another of those features of fibroid which serve to distinguish it from tubercular phthisis: the frequent concurrence of extensive disease with an abounding vivacity and abiding life. For although often it seems as if the patient must succumb, yet as often he rallies, and, renewing his conflicts and repeating his victories, he continues in the fervour of self-reliant hope to live and fight and to enjoy work.

Here, then, is the eventual outcome of a primitive dry pleurisy, which, after lasting for an uncertain time, has invaded the lung, altered or destroyed some of its structural constituents, consolidated portions of its parenchyma, and brought about ulcerous excavations therein. Here are well-defined pathological, corresponding with well-defined clinical, conditions moving forward together with constantly re-adjusted relations towards a definite issue. Here are an assemblange and progression of symptoms associated with or dependent upon an ulcerative destruction of more or less circumscribed non-malignant deposits in the lung. What is the name whereby we make known to each other the existence of this complex state? We call it *pulmonary phthisis*, and the term has so penetrated every department of thought and work in medicine that it can no more be rooted out. This final outcome of pulmonary fibroid invasion is therefore a pulmonary phthisis. And if nothing more could be said, here at last would be an end of the whole matter. But, for my own part, I believe that on this subject there is more to be said; and to those who have sufficient experience and settled convictions I regard it as a duty to say it. Such saying may clash with established opinion, assume the aspect of a retrograde movement, and be even inaccurate. Nevertheless, it ought to be welcomed; for genuine thought born of genuine work must always in science have its place and use. What, then, if under the term pulmonary phthisis there are included several states, which, although corresponding to the generic definition, are different in their characters, course, duration, and issues? If they exist, ought not such states to be named, and so named that the ideas which they express, and the distinctions which they embody, shall be preserved for future study and use? It cannot be a worthless knowledge which will enable one in a given case to predict with accuracy its future course, and say whether the subject of it is to live for five or for fifty years. And, furthermore, if such states have vindicated their right to be named, upon what principles shall the names be bestowed? Surely, if we wish to avoid confusion of thought and speech, surely if we wish to repress that needless ever-changing nomenclature, that substitution of words for ideas, that reproduction of old thoughts disguised under freshly furbished raiment, which in knowledge so often begets movement without progress, we shall make sure that the name given shall be based on some physical characteristic of the thing named; so that *whilst theories of its nature may change, the name bestowed* upon it, and by which it becomes everywhere and by everyone understood, shall remain unchanged.

Now, my contention is that our answers to all these questions should be in the affirmative. I contend that there is a general assemblage of pathological conditions upon which we may bestow the generic term phthisis; that included in this term are subsidiary groups of states, which, differing each from the other in some essential points of their pathological and clinical history, demand separate recognition; and that, in naming them, we should have exclusive regard not to the ephemeral theories of their nature, but to the abiding facts of their physical constitution. Guided by these considerations, I regard the ultimate condition of the lung invaded, altered, consolidated, and excavated by fibroid material as a phthisis; and seeing that the most obvious and unvarying fact in its physical constitution is the presence and action of this very fibroid substance, I am bold enough to call it fibroid phthisis. This boldness will doubtless call down upon me a storm of reprobation and denial; be it so. Confident that there is at least some just foundation for the position which I have taken, I must be content to endure and wait. In reply to this contention it will be said that the subject is no longer open to discussion; that experimental, pathological, and clinical inquiries concur to prove that there is but one phthisis, the sole originator of which is the tubercular bacillus; that there is neither room nor need for subsidiary classifications; and that their advocacy can be accounted for only by the ignorance or incompetence of the advocates. But these arguments, couched in such courtesies of modern controversy, are not so conclusive as they sound and seem. Many answers may be made to them, but on the present occasion I shall confine myself to two, which, as I venture to think, are neither light nor irrelevant.

In the first place, assuming the absolute unity of phthisis under the exclusive causation of the tubercular bacillus, this unity does not do away with the fact that there are included in it subsidiary groups which, for reasons already given and not refuted by the bacillary presence, require separate and permanent recognition. At present the bacillary hypothesis, although supreme in the domain of pathology, continues to be of but small account or even barren in the field of practical medicine. We cannot prevent the entrance of the bacillus into the organism; we cannot follow it into the secret places where it dwells and works; we cannot reach it by drugs, nor put an end to its multiplication by taking refuge among the mountain tops. But although we cannot eradicate the bacillus nor arrest its action upon the organism, we may perhaps succeed in helping the tissues to resist more or less successfully the attacks which it makes upon them and the destruction which follows in their wake. And, although in addressing ourselves to the furtherance of this object, we must have regard in the first place to the general well-being of the organism, we must not be unmindful of the different structural effects which arise from the unitary action of the bacillus. We must remember that sometimes these structural effects appear under the form of tubercles, sometimes under the form of caseous masses, sometimes under the form of fibroid consolidations, and sometimes as combinations of these forms, in which, however, one form is always predominant. Now, it can scarcely be denied that there is some difference of meaning in these differences of structural effects; that they pursue different courses; and that they react in different ways to the influences of climate, food, alcohol, and drugs. And if this be so, I can discover no valid reason why those different groups should not be recognised by distinctive names, nor can I understand how we are to preserve a complete loyalty to the uses of knowledge if we continue to refuse them recognition. It can be no invasion of the rights and privileges of the bacillary suzerainty to grant subordinate autonomies to the several groups of states which, arising under its influence and continuing through its presence, pursue independent courses and create widely different histories. Why under the generic name bacillary phthisis should we not recognise the subordinate independence of tubercular bacillary phthisis, caseous bacillary phthisis, and fibroid bacillary phthisis? Surely every just differentiation is a substantial gain, and every confounding of things fructively distinct a material loss. In the second place, I hold that the assertion that all ulcerations of non-malignant deposits in the lungs are bacillary remains unproved, and is opposed to the results of inquiries made by several competent observers. I contend, on the contrary, that there exist cases of ulcerative bronchiectasis and of fibroid lung with excavations in which, after repeated search by processes successful in veritable tuberculosis, no tubercular bacilli could be found. It is to such cases that I give the name of non-bacillary fibroid phthisis.

It may now be justly asked, Would anything be gained by establishing this distinction? I think much in many ways. It is, however, of the clinical gain alone that I shall at present speak. By adopting and carefully studying the proposed distinction, we should learn that the history of non-bacillary fibroid phthisis is quite different from that of bacillary tubercular phthisis, and that the treatment which would prove useful in the one might prove both useless and injurious in the other; for example, alcohol which is usually helpful in caseous, is usually hurtful in fibroid phthisis. If anyone will critically compare the broad facts making up the history of tubercular with those making up that of fibroid phthisis, I think he will become disposed to admit that the distinction now contended for is both real and considerable.

Let me bring to your remembrance a very few of the contrasting facts which are found in the two forms of phthisis now under consideration.[3] Tubercular phthisis is primarily of constitutional origin, and appears for the most part in the young; it is bilateral; its course is accompanied by elevation of temperature and rapidity of circulation, by progressive loss of flesh, strength, and colour, sometimes by laryngeal ulceration, and sometimes by sensations of painful exhaustion and malaise; it is usually rapid in its progress; the majority die within three years; and the few who, in consequence of fibroid complications, live for several years, enlarge the average duration of the disease to four or five. On the other hand, fibroid phthisis is usually of local origin, and appears for the most part in the middle-aged; it is in the main unilateral; it is unaccompanied by elevation of temperature or hurry of circulation; flesh, colour, and strength may remain but slightly affected for years; it is not incompatible with great bodily and mental energy; the urine almost always contains a little albumen; the progress of the malady is slow; œdema is never absent throughout; and death, which seldom occurs within five years, often lasts for thirty.

Here I must bring these lectures to an end. Acutely sensible of their shortcomings, I regret that they have not been worthier of the occasion, of the place, and of you. Nevertheless, I take courage of heart in the thought that those who have worked the most, and thought the deepest, and can judge the best will not be ready to forget, or to despise when remembered, the small but sometimes perfect uses of imperfect work.

ON THE
THERAPEUTIC VALUE OF ARSENIC IN ANÆMIA AND ATROPHIC CONDITIONS.

BY SAMUEL WILKS, M.D., LL.D., F.R.S.

ALTHOUGH the value of arsenic in many diseases is well known, yet I believe the extent of its efficiency has by no means spread through the profession at large, judging from the frequent scepticism one meets with when its use is suggested. I should therefore wish, as briefly as possible, to state my experience of the great value of this most remarkable remedy during many years of practice. It has been best known as a medicine in skin diseases, but this only of late years, for Addison, who followed directly in the school of Willan and Bateman, rarely ordered it. Next to its use in cutaneous affections has been its administration in neuralgic affections and ague; after that in special cases of various kinds. More recently the great value of arsenic has been recognised in anæmia; but it is not widely known, I believe, as being equally efficacious in various forms of cachexia, of which I am about to speak.

When a remedy acts—to adopt the expression of the older schools—as an alterative, by modifying nutrition in some unknown way, a question arises which is quite open to consideration: whether those diseases which succumb to its action may not depend upon the same cause; whether, indeed, they are not bound together by some common origin. Be this as it may, there can be no doubt that many of the cutaneous affections cured by arsenic have a gouty origin, and therefore it is not surprising that the same remedy has a great power in preventing attacks of gout. This I have known for many years, and in some cases have by its use undoubtedly kept the attacks in abeyance. Then, this gouty class of persons are often neuralgic, and it may be in them especially that arsenic is the best nervine remedy. I have certainly found it amongst the most efficacious medicines, and in some cases the only remedy. Thus, before the introduction of nitrite of amyl and glonoin for angina pectoris I relied mainly on arsenic, and in some cases kept off attacks for weeks when they had previously occurred almost daily; but this is by no means a novel treatment, for a reference to THE LANCET of May 26th, 1832, will show a letter setting forth the virtues of arsenic in this complaint. In some forms of nervous affection I have found it quite unique in its action. For example, a lady for many years has been the subject of ciliary neuralgia—that is, she has attacks of violent pain in the eyeball accompanied by intense congestion and lacrymation. No ophthalmic surgeon to whom she has applied has afforded her the slightest relief either by medicines or local applications. The only respite she has from her sufferings is during the time she is taking arsenic. How I became acquainted with the use of this remedy in asthma from one of my out-patients I described many years ago.

But the most remarkable effects of this remedy are seen in anæmia and various forms of cachexia and atrophy. My attention was first markedly drawn to it in this connexion owing to the controversy which took place between my late colleague, Dr. Alfred Taylor, and others in reference to the statement published in Johnston's "Chemistry of Common Life" in the year 1855 about the arsenic-eaters in Styria. Young girls were said to add to their charms by using it, acquiring blooming complexions, full rounded forms, and a healthy appearance. Soon afterwards I began to use arsenic in chlorosis with much benefit, but it was not until about ten years afterwards that I had some striking examples of its good effects. If I remember right Dr. Sutton of the London Hospital was then using it in the same class of diseases. The case I especially recollect was a lady about forty years of age, who was pronounced by myself and other physicians to be the subject of idiopathic anæmia, the form of disease subsequently discovered by a German, and styled "pernicious anæmia." Her bloodless and feeble condition compelled her to keep her bed, and it was never believed that she would rise from it again. I suggested arsenic as a possible useful remedy, and she began soon to improve, and in a few weeks was able to come to my house. I saw her some years afterwards, in 1874, when she was quite well. The case is more especially impressed upon my memory on account of the remarks of the husband. When I told him of the remedy which had cured his wife he expressed no surprise, saying it was just the medicine he should have thought of, for if he had a horse which was not "thrifty" he gave it arsenic, rendering it again plump and its skin glossy. Subsequent to this case I have had several of a similar kind, my last one being only a few weeks ago. It was that of a gentleman living at Holloway, and whom I saw with Dr. Blackstone. He had gradually grown anæmic and breathless, so as to be unable to leave his house, and he walked with much difficulty. I called it one of idiopathic anæmia, and feared that he would never recover. He took five drops of liquor arsenicalis, and in a month he was comparatively well. In most of the cases where arsenic has succeeded, iron had previously failed; and it is a question, therefore, whether the latter be of any use in the so-called pernicious anæmia. This, however, does not seem invariably the case unless the diagnosis is at fault. For example, a woman came into the hospital in so bloodless a state that she could not leave her bed, and it was said that iron had been given in vain. An examination of the blood displayed, as was thought, characteristically altered blood-globules, and arsenic was prescribed. After a long course of this medicine she was no better, when iron was ordered for her. She then immediately improved, and left the hospital well.

---

[3] That is, there exist in the organism certain peculiarities of soil which enable the bacilli to grow and multiply.

I remember two cases of anæmia with some discolouration of the skin, suggesting the existence of Addison's disease, and which were cured by arsenic. One was a lady whom I saw as long ago as 1869, who had gradually been getting thin, sallow, and bloodless. She was first thought to have liver disease, and then Addison's disease; but of these there was no evidence, and I recommended arsenic. She speedily recovered. The other case was that of a lad who was sent to me from Suffolk by Dr. Manthorp as he was supposed to be the subject of Addison's disease. He was anæmic, sallow, very feeble, and breathless on exertion. Arsenic was given him, and he completely recovered.

It is another class of case, however, which especially prompted me to take up my pen and extol the virtues of arsenic, for although its efficacy is known in anæmia, I do not find that a knowledge of its merits has extended to wasting and general cachexia. It was in the year 1868 that I went to see a lady who was confined to her bed and in an extreme state of emaciation. I found on physical examination nothing tangible except an enlarged spleen. She had been staying at a friend's house in a doubtfully malarious district, and therefore might have been infected by ague poison. Arsenic was given, and she made a rapid and complete recovery. It is well known that in cases of inveterate malarious poisoning arsenic is often the best remedy, but the possible existence of such a cause will not account for the marvellous effects of arsenic in other cases; and I have notes of two patients who lived at Margate, where a miasmatic influence could not be suspected. The first case was that of a lady sent to me by Dr. Thornton. She was much impoverished, and at the same time had loss of appetite and other gastric symptoms, so that I suspected early malignant disease. I could not, however, prove this, and suggested a trial of arsenic. The result is seen in a letter which I received from Dr. Thornton, dated December 1875, in which he says, "I fancy you will be pleased to know that Mrs. B——, for whom you prescribed arsenic, and of whom you took not the most sanguine view, thinking probably that some hidden malignant disease might develop itself, strange to say, is now convalescent—that is, she has recovered her natural complexion, lost all pains and feeling of debility, and, indeed, is as well as she has been for the last few years. I never saw a more unpromising case, and I do not remember ever to have seen anyone improve so steadily as she did under the influence of arsenic (?); at all events, she was very ill, and now she is comparatively well."

The second case from Margate was that of a young man resident in that town, and brought to me by Mr. Dunstan of Tollington-park. He was twenty-one years of age, and had been gradually wasting away for many months until he had become, as his friends said, a perfect skeleton. He certainly was emaciated to a most extreme degree. On examination I failed, like other medical men, to discover any disease, but saying that if the patient had been an infant he would have been called the subject of marasmus. I suggested arsenic as the only likely remedy to do him good if he had no organic disease, and four drops of the solution were prescribed three times a day. He immediately began to recover; in two weeks he had gained five pounds, and in a few more weeks he was perfectly well.

Another case where the remedy was of great service was that of the Rev. Mr. S——. He had been acting as curate both in London and Brighton, but, his health gradually failing, he was obliged to give up his duties. No medical advice was of any value to him, and he was recommended to take a voyage to Australia. He, however, grew worse and worse, and on his arrival at Melbourne he was sent into the hospital. After a while he was again placed on board ship, under the care of a medical man, and sent home to Hampstead. He was carried into the house, being far too weak to walk, and when I saw him I found him as wasted as any living man could be. He was lying on a couch too feeble to rise, and very little more than a skeleton. His weight on leaving the ship was 5 st. 7 lb. With the exception of a cardiac bruit I found no disease, and as he had had every kind of medicine, and every variety of essences of meats and other foods, there seemed little for me to do; but I prescribed arsenic. He slowly began to improve, and in a few weeks he was able to leave his home and visit me. He walked feebly, but his limbs had increased in size, and he weighed 7 st. 10 lb. He then left for the country and the Continent.

I have now mentioned a sufficient number of cases to show the value of an old remedy, and certainly one of the most remarkable in the Pharmacopœia. I would not have it supposed that it cures all cases of anæmia and atrophy, or that it has never failed in my hands; for if I collected all the cases in which I have given it and noted the result, it is probable that the failures might equal the successes. But an explanation will show that a statistical method of arriving at the truth is of no value, seeing that the cases where the remedy was administered were not of a like kind, and that the unsuccessful cases, although resembling in outward appearance those of simple anæmia and atrophy, were in the majority of instances examples of early malignant and other organic disease. The only cases which can be rightly compared are those of a like kind, but the question of its comparative value under the circumstances named cannot affect in any way the undoubted fact of its curing numerous cases of apparently fatal disease. No question can arise as to the efficacy of a medicine when it is prescribed for a person who is weekly and monthly declining in health, and who as rapidly, or more rapidly, regains his health and strength under its use. When this has been observed in a large number of instances, the proof of its value is complete. I have never given very large doses, generally four or five drops of the liquor arsenicalis three times a day, or a little more of the soda preparation. I have never observed any injurious effects from its long use, although, as is known, it becomes absorbed into the system, the urine showing its presence many weeks after its administration has ceased. I will not pretend to say how the remedy acts. Why, when wasting is going on and the blood-corpuscles becoming disintegrated, arsenic should stop the process, and the globules begin to grow, or why it should allow the carbon to be stored up as fat, I do not know. I lay the clinical facts before my readers, and hope that those to whom they are not altogether new will excuse my doing so in the wish to make their knowledge and mine more extended and useful.

Grosvenor-street, W.

BEQUESTS.—The late Miss Duthies of Ruthvieston has, we understand, bequeathed the following among other legacies to public institutions in Aberdeen:—The Royal Infirmary, £2000; the Aberdeen University, for two medical scholarships, £2000; the Hospital for Incurables, £500; the Lying-in Institution, £500; the General Dispensary, £500; the Hospital for Sick Children, £500.

ON A CASE OF OBTURATOR HERNIA.

BY RICKMAN JOHN GODLEE, M.S.,
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

CASES of obturator hernia are so uncommon and present such difficulties of diagnosis and treatment, that it may be well to place the following one on record, although strangulation had been in existence for so long that there was little hope of any treatment giving relief, and that adopted did not save the patient.

E. F——, a woman aged forty-five, was admitted under my care into University College Hospital on May 29th, 1884, at 8 P.M. with symptoms of intestinal obstruction. We were unable to obtain any good previous history of the case, and the notes do not mention the length of time from which she had been suffering from symptoms of complete obstruction; but they had been in existence for several days, I think about five, and she had for some time been bringing up fæcal vomit. She was on admission in a state of great collapse, with small pulse, cold extremities, and a marked blue colour of the skin. She complained principally of pain about the region of the umbilicus, or rather above it, and it was only on carefully examining all the hernia regions that it was found that there was distinct tendernees and slight fulness in the left Scarpa's triangle. On questioning her about this point, she allowed that for a long time past she had been subject to pain in this part, which extended down the front of the thigh and which was subject to variations, and was relieved by lying down; but it was evident that occasionally it had caused her considerable inconvenience. The diagnosis apparently lay between some twist or internal strangulation and an obturator hernia (though the possibility of the obstruction depending upon the presence of a tumour was not lost sight of,) and, considering that the former was not improbable, and that if it were the latter it could probably be safely dealt with by abdominal section, I proceeded to operate at 9 P.M. An incision about four inches long was made between the umbilicus and the pubes through the abdominal wall, and a piece of great omentum which lay beneath the incision and which was much matted together was first drawn out of the wound. The index finger of the left hand has then at once passed down to the obturator foramen, and there was no difficulty in detecting the fact that a portion of bowel was tightly strangulated in the upper part of the obturator foramen. It was quite impossible without employing undue force to draw this back, so a blunt-pointed bistoury was carefully passed down along the finger, and by directing the edge inwards the constricting ring was divided and the gut was reduced. The division of the stricture at such a depth from the surface and with the coils of intestine surrounding the finger was a matter of some difficulty, but when it was accomplished the gut was drawn up with ease. It proved to be a part of the small intestine, about two inches long; it was of a bluish colour, but rapidly became red under observation. It was also seen that the previous traction had caused two slight rents in the peritoneal coat, which passed obliquely across the gut, the edges of which were accordingly drawn together with continuous sutures of very fine catgut. The lacerations bled readily. The portion of protruded omentum was then ligatured in two places and removed, the stump being returned, and the abdominal incision was approximated. The patient did not rally after the operation, though she took nourishment, including a good supply of brandy, well. The vomiting stopped, but her extremities remained cold and became more blue, and her skin was bathed in a cold perspiration. Towards the afternoon of the following day an excited delirium set in, and in the evening she died.

The autopsy revealed the fact that the portion of gut which had been constricted was about eighteen feet from the pylorus, and that its mucous membrane was dark and opaque from extravasated blood. There was slight peritonitis around the piece of gut which had been included in the hernia, the coils in this region being adherent to one another and to the pelvic wall by recent lymph. There was also a little reddish fluid in the peritoneal cavity. The hernial sac was of small size, and lay immediately beneath the pectineus muscle. Beyond considerable hypostatic congestion of the lungs, nothing else worthy of note was learnt from the post-mortem examination.

I do not wish to bring this case forward in order to advocate the method of treating obturator hernia by abdominal section in preference to the operation in Scarpa's triangle, though it is probable that the latter is a more difficult procedure. The abdominal section is not an altogether simple matter, and it no doubt involves certain risks which are not encountered in the other operation. It was selected in this case because the symptoms, while obvious enough to direct attention especially to the obturator region, were not thought to be clear enough to negative the possibility of the mischief being found in the locality to which the greater part of the pain had been constantly referred; and it was argued that if the latter had been the case, an abdominal section following the necessarily tedious operation in the thigh would have been a very serious matter in the exhausted condition of the patient. An important lesson to be learnt from the case is the extreme care which should be exercised in making traction on the intestine in a patient whose tissues, as they were in this case, are all in a very flabby and easily lacerable condition.

Wimpole-street, W.

WHAT IS THE EXPLANATION OF ACQUIRED IMMUNITY FROM INFECTIOUS DISEASES?

BY GEORGE M. STERNBERG, M.D.,
MAJOR AND SURGEON, U.S.A.

IT is well known that in the specific infectious diseases of man and of the lower animals a single attack commonly confers immunity from subsequent attacks. There are, however, numerous exceptions to this rule, and the immunity conferred is not absolute, but has a variable value, which depends partly upon individual susceptibility, partly upon the physical vigour of the individual when subsequently exposed, and partly upon circumstances relating to the nature of the exposure—e.g., concentration of poison, mode of infection, &c. There is also evidence that in some cases at least the time which has elapsed since a first attack is an important factor in determining immunity when a subsequent exposure occurs. Even in small-pox and in yellow fever, diseases in which a single attack is in most cases protective during the lifetime of the individual, fatal second attacks occasionally occur. Nevertheless the general law of immunity as a result of a single attack is well established for a majority of the acute infectious diseases.

It is evident that the immunity which results from inoculation with an "attenuated virus"—as, for example, in Pasteur's protective inoculations against anthrax, or from vaccination—is of the same nature, and that a satisfactory explanation must include all established facts of this class. Upon taking a broad view of the question, it will be seen that it includes also the facts relating to relative race immunity, such, for example, as the comparative mildness of yellow fever in the negro, the alleged liability of the esquimaux to suffer a fatal attack of small-pox as a result of vaccination (Grawitz), the immunity of Algerian sheep from anthrax, &c.

Naturally this question has attracted the attention of the leading investigators in the field of experimental pathology, for its inherent interest and practical importance are apparent. Three explanations have been offered to account for the phenomena in question, which may be stated as follows:—(1) The "exhaustion theory," advocated by Pasteur, which supposes that some substance present in the body of a susceptible individual up to the time of a first attack, and which is essential for the development of the specific germ of the disease, is exhausted during the attack, and that consequently this particular germ is unable subsequently to multiply in the body of this individual. (2) The "antidote theory" advocated by Klebs and recently supported by Klein.[1] This theory supposes that some chemical substance is produced during the attack which is inimical to the development of the germ, and which, remaining in the body of the animal, prevents its subsequent development. (3) The vital resistance theory, which supposes that immunity is due to an acquired tolerance on the part of the living cellular elements of the body to the poisonous products evolved by disease germs, to which they probably owe their pathogenic power, and a consequent ability to resist invasion by them. According to this view, individual and race differences in susceptibility, as well as the more or less perfect immunity resulting from a single attack of any one of the specific infectious diseases, are phenomena depending upon differences in vital resisting power, either inherited or acquired. The last-mentioned theory is referred to by Klein in his recent work on "Micro-organisms and Disease" in the following language:—"Some observers (Grawitz, &c.) are not satisfied with this theory" [the antidote theory], but assume that, owing to the first attack, the cells of the tissues so change their nature that they become capable of resisting the immigration of a new generation of the same organism. There is absolutely nothing that I know of in favour of such a theory; it is impossible to imagine that the cells of the connective tissues, of the blood, and of other organs, owing to a past attack of scarlatina, become possessed of new functions or of some new power—as, for instance, a greater power of oxidising, or the like."

---

[1] Micro-organisms and Disease, Practitioner (London), vol. xxxiii, No. 4, p. 249.

As the present writer is perhaps included in the "&c." ("Grawitz, &c.") of the above quotation, he feels called upon to say something in favour of the theory thus summarily disposed of, which seems to him to be the only one thus far offered which is at all tenable, and which he advocated in an article published in the *American Journal of the Medical Sciences* of April 1st, 1881, which has the precedence over the paper by Grawitz by a few days, the latter having appeared in Virchow's *Archiv* on the 8th of the same month. In order that the two explanations which I reject as untenable may be fairly presented to the readers of the present paper, I shall quote verbatim the arguments advanced in their support by their most prominent advocates.

The first hypothesis (1) is supported by Pasteur in the following language:—"It is the life of a parasite in the interior of the body which produces the malady commonly called 'choléra des poules,' and which causes death. From the moment when this culture (i.e., the multiplication of the parasite) is no longer possible in the fowl, the sickness cannot appear. The fowls are then in the constitutional state of fowls not subject to be attacked by the disease. These last are as if vaccinated from birth for this malady, because the fœtal evolution has not introduced into their bodies the material necessary to support the life of the microbe; or these nutritive materials have disappeared at an early age. Certainly one should not be surprised that there may be constitutions sometimes susceptible and sometimes rebellious to inoculation—that is to say, to the cultivation of a certain virus, when, as I have announced in my first note, one sees a preparation of beer yeast made exactly like one from the muscles of fowls (bouillon) to show itself absolutely unsuited for the cultivation of the parasite of fowl cholera, while it is admirably adapted to the cultivation of a multitude of microscopic species, notably to the bactéride charbonneuse (bacillus anthracis). The explanation to which these facts conduct us, as well of the constitutional resistance of some individuals, as of the immunity produced by protective inoculations, is only natural when we consider that every culture in general modifies the medium in which it is effected; a modification of the soil when it relates to ordinary plants; a modification of plants and animals when it relates to their parasites; a modification of our culture liquids when it relates to 'mucédines,' 'vibrioniens,' or ferments. These modifications are manifested and characterised by the circumstance that new cultivations of the same species in these media become promptly difficult or impossible. If we sow chicken bouillon with the microbe of fowl cholera, and, after three or four days, filter the liquid in order to remove all trace of the microbe, and subsequently sow anew in the filtered liquid this parasite, it will be found quite powerless to resume the most feeble development. The liquid, which is perfectly limpid after being filtered, retains its limpidity indefinitely. How can we fail to believe that by cultivation in the fowl of the attenuated virus we place its body in the state of this filtered liquid, which can no longer cultivate the microbe? The comparison can be pushed still further; for, if we filter the bouillon containing the microbe in full development, not on the fourth day of culture, but on the second, the filtered liquid will still be able to support the development of the microbe, although with less energy than at the outset. We comprehend, then, that after a cultivation of the modified (*atténué*) microbe in the body of the fowl, we may not have removed from all parts of the body the aliment of the microbe. That which remains will permit a new culture, but in a more restricted measure. This is the effect of a first inoculation; subsequent inoculations will remove progressively all the material necessary for the development of the parasite."[2] In commenting upon Pasteur's explanation of acquired immunity in the chapter on "Bacteria in Infectious Diseases" in my recent work I remark:[3] "It is a little surprising that after disproving by the experimental method the hypothesis last mentioned"—viz., the antidote theory adopted by Klein—"which had been proposed by a member of the French Academy in explanation of the phenomenon in question, Pasteur did not, in accordance with his usual custom, attempt to establish his own hypothesis upon a firm foundation by an experiment which at once suggests itself. If a fowl which is protected against cholera, or an animal which is protected against anthrax, owes this protection to the fact that a certain material which is required for the development of the microbe of fowl cholera, or for the anthrax bacillus, has been exhausted in the course of the modified form of the disease to which immunity is due, then the flesh of such an animal made into bouillon should not constitute a proper culture medium for the organisms in question. The writer ventures to predict that the result of such an experiment would not be favourable to Pasteur's hypothesis, and that it will be found that the micrococcus of fowl cholera can be cultivated in bouillon made from the flesh of a protected animal, and that the bacillus of anthrax may multiply freely in the blood, or in an infusion of the flesh, of an animal which, before it was killed for the experiment, possessed immunity against the disease anthrax."[4]

Since the above was written, Salmon in the United States and Klein in England have reported the results of experiments which show that the prediction made was well founded.

Salmon says, in a recent communication to *Science*:[5]—"I trust, however, you will pardon me for calling your attention to the fact that more than two years ago I demonstrated that immunity was only relative, never absolute; that the most susceptible individual possessed a certain degree of immunity which can be accurately measured; and that *all* degrees of immunity may be overcome by a sufficient increase in the dose of virus. The immunity of the animal body, then, in no sense resembles the exhausted cultivation liquid in the flasks of Pasteur and Tyndall, which no increase in the amount of virulent material added can ever induce to support the development of new generations of the microbe, and the honour of demonstrating this radical difference is due to American investigations. I went further than this, however, and showed that this theory of our European friends was absolutely untenable, because broth made with distilled water from the flesh of an animal that had been granted a very complete immunity was just as favourable a medium for the growth of the virus as that made from susceptible animals; and that such virus lost nothing in virulence by being grown in such a medium. I will not trouble you with the theory of immunity which I developed from these experiments. Like other American work, it may have no value; but it may interest you to know that an able German writer, in the last number of Virchow's *Archiv*, has propounded a theory which in its most important points is identical with my own."

In referring to this theory as his own, Salmon seems to have overlooked the fact that I offered the same explanation of acquired immunity in my paper, already referred to, which was published in the *American Journal of the Medical Sciences* for April, 1881.

Klein says, with reference to the exhaustion theory:—"On careful analysis it will be found that it is not capable of explaining the facts of the case. As we mentioned in a former chapter, cattle inoculated with blood of a guinea-pig dead of anthrax become affected with anthrax, which, although not fatal, is nevertheless sometimes very severe. The animal recovers, and is now, for a time at least, secure against a second attack. But there is absolutely no ground for the assumption that if an infusion of the tissues of this animal were made the bacillus anthracis sown in it would not thrive luxuriantly, seeing that bacillus anthracis grows upon almost anything that has a trace of proteids. Similarly, when of the tissues of a guinea-pig, or mouse, or rabbit, dead of anthrax, an infusion is made, and this is used as nourishing material for bacillus anthracis in artificial cultures, it is found that these latter thrive splendidly. There is then no reason whatever for assuming that, after one attack of illness the blood and tissues become an unfavourable soil for a second invasion of the same organism, and that this change is due to the exhaustion of some necessary chemical compound."[6]

[4] Op. cit., p. 248.
[5] Sept. 26th, 1884, p. 303.

In my own paper, heretofore referred to, in the absence of experimental data I argue as follows:—"Let us see where this hypothesis leads us. In the first place, we must have a material of small-pox, and a material of measles, and a material of scarlet fever, &c. Then we must admit that each of these different materials has been formed in the system and stored up for these emergencies,—attacks of the diseases in question,—for we can scarcely conceive that they were all packed away in the germ cell of the mother and the sperm cell of the father of each susceptible individual. If, then, these peculiar materials have been formed and stored up during the development of the individual, how are we to account for the fact that no new production takes place after an attack of any one of the diseases in question? Again, how shall we account for the fact that the amount of material which would nourish the small-pox germ to the extent of producing a case of confluent small-pox may be exhausted by the action of the attenuated virus (germ) introduced by vaccination? Pasteur's comparison of a fowl protected by inoculation with the microbe of fowl cholera with a culture fluid in which the growth of a particular organism has exhausted the pabulum necessary for the development of additional organisms of the same kind does not seem to me to be a just one, as in the latter case we have a limited supply of nutriment, while in the former we have new supplies constantly provided of the material (food) from which the whole body, including the hypothetical substance essential to the development of the disease germ, was built up prior to the attack. Besides this, we have a constant provision for the elimination of effete and useless products. "This hypothesis, then, requires the formation in the human body, and the retention up to a certain time, of a variety of materials, which, so far as we can see, serve no purpose except to nourish the germs of various specific diseases, and which, having served this purpose, are not again formed in the same system, subjected to similar external conditions, and supplied with the same kind of nutriment."

It hardly seems worth while to give further attention to this explanation offered by the great chemist to whom we owe so much, but who, if we may judge from his reasoning in this instance, is not equally great as a physiologist. We proceed, therefore, to consider hypothesis No. 2.

(To be continued.)

REMARKS ON

NINE CASES OF DEATH BY HANGING

(SIX EXECUTIONS AND THREE SUICIDES).

By R. J. KINKEAD, M.D. Dub.,
LECTURER IN MEDICAL JURISPRUDENCE, QUEEN'S COLLEGE, GALWAY.

It has been my lot to have rather an extensive experience in death by hanging, both by execution and suicide; although the scientific value of such experience has been largely reduced by the want of post-mortem examinations in all the cases save one, yet something may be learned from a report of them. In the case of executions the prison surgeon has no power to make a post-mortem unless ordered by the coroner. On sentence of death being passed, the prisoner is remitted to the local prison whence he came, and given into the custody of the governor. He remains in his custody, subject to the special rules for condemned prisoners, until the day fixed for execution. The death warrant is in the meantime issued to the sheriff, who has charge of everything connected with the execution. He it is who provides the gallows and engages the executioner, who acts as his officer. The sheriff is not bound to engage the public executioner; he can arrange with anyone he likes. In case no executioner can be found the sub-sheriff is bound to act as executioner, and in case he fails or refuses the high sheriff himself must discharge the duty. On the morning fixed for the execution the sub-sheriff comes to the prison, presents the death-warrant to the governor, and demands the body of the condemned, who is handed over to his custody, and by him to the executioner. Thus the condemned passes from the custody of the prison authorities entirely, and neither the governor nor any prison officer can interfere with him any more. They are, however, bound to assist the sheriff in the discharge of his duty; and by Act of Parliament the governor or deputy governor, the chaplain, and medical officer of the prison must be present at the execution, and make certain statutory declarations. But once the body of the criminal has been handed over to the sheriff, he passes completely from under the custody and control of the prison officials. It is necessary that this should be clearly understood, as there is a general impression to the contrary, and if, as sometimes happens, an accident occurs during an execution, the prison officers are supposed to be accountable, and to have an interest in hushing it up. It cannot be too clearly understood that they have nothing whatever to do with an execution beyond assisting the sheriff and acting as witnesses, and that the entire responsibility rests with the sheriff. Under this mistaken idea of the prison officers' duty it has been urged that the post-mortem examination on the body of an executed criminal should not be made by the prison surgeon, but that an independent medical man should be present at the execution, and give evidence at the inquest. I am not aware that there is any law which authorises a prison surgeon to make a post-mortem examination, on either an ordinary prisoner or executed criminal, without the requisite permission either of the relatives in the former case, or of the sheriff in the latter; and I am not certain whether the sheriff, although the legal custodian of the body, can give permission. He is debarred from the power, given to those in custody of a dead body by the Anatomy Act, of giving it for anatomical purposes. Consequently in cases of executions I have been unable to make a post-mortem examination, unless by order of the coroner. The body having passed to the custody of the sheriff I have felt I had no power as a prison officer to interfere with it. In the case of suicides, in addition to the difficulty likely to arise from the necessity of obtaining the permission of the relatives, the prison surgeon is prevented from making a post-mortem examination even at the coroner's bidding by an order from the executive; that in the case of any prisoner dying in prison, the post-mortem examination, if directed by the coroner to be held, shall not be made by the prison surgeon, but by an independent medical man, to be called in by the coroner for that purpose. This raises a question of law. In private practice, if an inquest is necessary, it is inexpedient that the medical attendant should make the post-mortem examination if any possibility of any question concerning the treatment could arise. In the case of a prisoner dying in prison an inquest must be held, and as the question of treatment, both medical and otherwise, necessarily arises, it is obviously expedient, unless the cause of death is very clear and the proof of good treatment convincing, that a post-mortem examination should be made, and that the duty should be discharged by "an independent medical authority." But as matters stand, the medical officer may be placed between the hammer and the anvil. The coroner is not under the authority of the executive. He is an independent judge, and can refuse to receive orders either from the Home Secretary in England or the Lord Lieutenant in Ireland. Suppose he orders the medical officer to make a post-mortem examination: if the surgeon obeys the coroner, he must disobey his superior officers; if he refuses to make the post-mortem examination, the coroner can commit him for contempt of court.

Shortly after the circular was first issued the coroner of the city of Dublin refused to recognise its authority, and directed the medical officer to make a post-mortem examination on the body of a criminal executed for murder. The Royal Commission on Prisons in Ireland has recommended that "governors be requested, whenever an inquest is about to be held, to inquire of the coroner whether a post-mortem examination is to be made, and, if he should reply in the affirmative, to inform him that" the Lord Lieutenant "wishes such examination to be made by a medical practitioner not connected with the prison service." This mode would certainly be an improvement; it would prevent the medical officer being placed in the very awkward predicament of having to choose which authority he should obey: and there are few coroners who would refuse to comply with a request so conveyed. In only one case of the nine I have seen did the coroner deem a post-mortem necessary. Since January, 1880, there have been ten men executed, and three have committed suicide by hanging in Her Majesty's Prison at Galway. I have been present at the execution of six of these men, and saw the bodies of the suicides within a few minutes of their being discovered.

---

[6] The Practitioner, London, Oct. 1884, p. 247.

In eight of the executions Marwood was the hangman, and although he discharged his duty with celerity and death was instantaneous, yet it seemed to me that the time must have appeared terribly long to the criminal from the commencement of the preparations until the bolt was drawn. My observations have also convinced me that in no case should one executioner attempt to hang more than one person at a time; for not only is it likely that an accident may result—as actually did happen in one case—and the death of the criminal be prolonged, but the mental strain and agony of the miserable criminal waiting on the drop until the others are prepared must be something awful. To me, standing looking on, the time seemed interminable, although the work was done rapidly and did not occupy more than a minute or two. What must it have been to the unfortunate creature on the brink of eternity! This will be fully understood from a description of the process. The prisoner's arms are pinioned in the condemned cell. A belt is buckled round the waist; to this belt are attached two straps, which, when the belt is in its place, are about an inch or two in front of and above the anterior superior spine of the ilium. The arms are fastened to the side of the belt by these straps, so that the fingers can barely cross in front, and the elbows project somewhat behind. The pinioning being effected, the prisoner is marched to the scaffold and placed on the drop, immediately under the ring in the cross-beam, to which the rope is attached; the legs are then fastened together by means of a strap placed between the knees and the ankles. Next, the noose is placed round the neck, drawn firmly round the throat, and kept in position by a washer or ring. The white cap is then put on, and the executioner, stepping back, pulls the bolt. Now, it is evident that, no matter how dexterous and practised the executioner may be, the strapping the legs, adjusting the rope, and putting on the cap must take time; and if the prisoner is left standing while the same thing is being done to one or two others, his suffering must be very terrible. What it actually is I suppose no one can conceive; but in one case, although a single execution, and done very quickly, the man fainted, and was actually falling sideways when the bolt was drawn.

In Marwood's executions he used the long drop, and placed the knot under the chin. The rope hung down behind the prisoner's back from the ring in the cross-beam, and looped up from below the waist to its attachment under the chin. Thus it will be seen that the length of the drop was something more than the prisoner's height. This arrangement worked well if the prisoner was steady; but if restless, then there was the danger of what actually happened once—of the loop of the rope catching the convict's elbow as the body fell, and so preventing death being instantaneous. The first man I saw hung was executed in Jan. 1880. He was a tall, powerfully-built fellow, and met his death with great fortitude. One hour and a half after the execution, assisted by Dr. Pye, professor of anatomy, I made a post-mortem. Fæces had not been passed, but there had been an emission of seminal fluid. On dissecting the neck, we found most of the tissues torn through, the body of the third cervical vertebra was broken diagonally across and separated for at least two inches and a half to three inches from the remaining portion, the spinal cord was torn through, and in fact the head was retained in connexion with the trunk merely by the skin, which was not even abraded, a few muscular shreds, and the vessels on the right side. The trachea and œsophagus, the carotid artery and jugular vein on the left side, were torn through, and the tissues were emphysematous. On opening the thorax, nothing particularly abnormal was discovered in the lungs; they were slightly congested, but not to a very appreciable extent; the left heart was empty and firmly contracted, but on the right side both auricle and ventricle were full of frothy blood, the air escaping from the ruptured trachea having been evidently sucked down through the jugular vein.

The next execution I witnessed was in January, 1883. The prisoner walked with tolerable firmness to the scaffold, but appeared to faint on it, for just as the bolt was pulled he fell sideways towards the left; the drop too was evidently a very long one, as the loop of the rope was below the level of his knees. To ascertain roughly the lesions producing death did not need a post-mortem, as all the tissues, save about from one and a quarter to two inches of skin on the right side of the neck, were entirely severed. In fact, had it not been for that small portion of skin he would have been completely decapitated. I attribute this result to an excessively long drop, to a thin neck, and to a rotary motion being imparted by the man's fainting, so that the pull on the body falling did not act in the line of the long axis of the neck, but partly laterally. The next two men were executed two days after. The coroner did not deem a post-mortem examination necessary, but, from an external examination, I have no doubt that the bones of the vertebræ were separated in each case. In the first case I have recorded there was actual fracture of the body of the third cervical vertebra; in the second case the separation took place between the bodies of the second and third cervical vertebræ; and, as far as I could judge in the last two, luxation was about the same place; the ends of the bodies of the vertebræ could be distinctly felt separated from each other by at least two inches and a half.

If I recollect rightly, the evidence in the Dublin executions was to the effect that in all cases the vertebral bones were torn apart and the spinal cord severed. In the four cases which occurred while I was absent from Galway no post-mortem was made, but the gentlemen who discharged my duty have informed me that they had no doubt as to separation of the bones in three. In the fourth, the case in which the rope caught under the elbow, the doctor's evidence at the inquest was that there was no dislocation or fracture of the neck, and that death resulted from strangulation.

(To be continued.)

A CASE OF

HIGH AMPUTATION FOR GANGRENE OF THE FOOT; OBSTRUCTION OF THE POPLITEAL ARTERY BY HYDATID CYSTS.

By H. MALLINS, A.B., M.B., M.Ch.

John T——, aged seventy-four, a labourer, always enjoyed good health until about seven years ago, when, owing to some slight injury, an ulcer formed on the anterior aspect of the middle third of the left leg. This ulcer seemed always to have been extremely painful, and for its relief, according to his account, every remedy, orthodox and unorthodox, had been tried without avail. At the end of last summer, the pain having become more severe, owing to a sloughing tendency which the ulcer began to exhibit, he was admitted into the Norwich Hospital, where he remained several weeks. Under the treatment adopted great improvement followed, and at the time of his discharge the ulcer was all but healed. A few weeks later, however, the whole foot of the affected side began to show signs of disease, the ankle became œdematous, and several of the metatarso-phalangeal joints suppurated and discharged. This recrudescence of the disease was attended with great suffering, the climax of which was reached at the beginning of January, when gangrene of the great toe showed itself. Amputation of the limb was now proposed, and, the risks of the operation having been duly explained, eagerly assented to. The operation was performed under chloroform on January 11th, by the method of long anterior and short posterior flaps, the femur being sawn through at the junction of the lower and middle third. On applying the tourniquet no pulsation of the femoral artery could be detected. Subsequently, when the fleshy parts were divided, the artery was found to be completely plugged by a firm clot. The collateral circulation seems to have been pretty well established, as six vessels required ligature. The wound having been well cleansed with dilute carbolic solution, a dressing of plain absorbent wool was applied. Everything proceeded favourably for the first forty-eight hours, when the temperature began to rise. On dressing the wound the anterior flap was found to have commenced to slough. Gangrene of the entire stump rapidly ensued, with a fatal result on the fifth day.

On examining the vessels of the amputated limb, the popliteal artery was observed to be much enlarged, presenting a fusiform dilatation, about an inch wide and four inches in length. In the process of dissection, the swelling having been accidentally pricked with the knife, a white matter, suggestive at first sight of pus, spurted out. On laying the swelling open, however, no pus could be detected. The walls of the artery were found to be thickened, but the main bulk of the dilatation was constituted by its contents, which consisted of a mass of hydatid cysts, varying in size from that of a very small pea to that of a good-sized raisin. Their walls in every case were collapsed. No hooklets could be discovered with the microscope. To clear up any doubt as to their true nature, a few specimens were sent to Dr. T. Spencer Cobbold, who most kindly examined them, and expressed the opinion that "they are unquestionably true hydatids. The ectocyst displays well-marked characteristics appertaining to echinococcus veterinorum."

Remarks.—It was the paper of Mr. J. Hutchinson, read before the Royal Medical and Chirurgical Society on Dec. 11th, 1883, urging the safety and expediency of high amputation in senile gangrene, that led to the undertaking of the operation in the foregoing case. It had been originally intended to amputate at the knee, but the existence of a small purulent depôt close to the popliteal space led to a suspicion of the healthiness of the tissues in its vicinity. One point to which it is desired to call attention is the early sloughing of the anterior flap. The experience of St. George's Hospital is, according to Mr. T. Pickering Pick, decidedly adverse to long anterior flaps, sloughing having taken place sixteen times in twenty-nine cases. The skin of a man aged seventy undergoes a certain amount of atrophy, a process in which its nutrient bloodvessels doubtless share. In the formation of a skin flap numerous vessels going to it must be divided, thus diminishing its vitality. Moreover, it is not improbable that a slight sloughing is quite sufficient to start off the process of gangrene afresh. For the foregoing reasons the method of long anterior flaps would seem to be unadvisable in amputation for senile gangrene. Though hydatids are found in many different situations in the human body, they seem to take up their abode in the bloodvessels but very rarely. In M. Davaine's analysis of 373 cases of hydatids, as given in Dr. T. Spencer Cobbold's work on "Entozoa," two cases occur in which the pulmonary vessels were the site of the cysts. As far as I can ascertain, these are the only cases of the kind hitherto recorded. In conclusion, it may be pointed out that there was very probably some connexion between the chronic ulcer of the leg and the plugging of the popliteal artery; either diminished blood-supply or pressure on the nerve from the bulging of the artery, leading to diminished vitality of the affected part. The constant and very severe pain would indicate the latter as the more probable cause.

Watton, Norfolk.

NEW REMEDY FOR CHOLERA.

By SHAMSUDIN J. SULEMANI, L.M. BOMBAY.

DURING the latter part of the epidemic of cholera, which broke out in July last at Baroda (a town in India), five marked cases of this disease were treated with jadvari khatai, papita, narjili daryai, and cardamom seeds; four of these were cured and one proved fatal. The above-mentioned four drugs were mixed and given in ten-grain doses to adult patients every hour or two, according to the severity of the symptoms; in each case three or four doses were used. The following are the notes of the cases in question:—

CASE 1.—A girl of about twelve was attacked with cholera at 1 A.M., and seen by me at 6 P.M. the same day. Her body was cold, pulse almost imperceptible, eyes sunken, frequent purging, stools watery and copious, and of the colour of rice water. There was suppression of urine of twelve hours' standing. Before I saw her she had been given chlorodyne and stimulants, but without any effect. Three doses of the above medicine were administered to her, the second dose being given one hour after the first, and the third after two hours. Soon after the administration of the first dose purging diminished and the pulse became perceptible; the second dose was followed by marked improvement, and the extremities and the trunk became gradually warm. She voided urine some two hours after the third dose, and was then out of danger.

CASE 2.—An adult male commenced purging and vomiting at 6 A.M., and was treated with chlorodyne and stimulants, but without relief. I saw him at 5 P.M. the same day, and found him much exhausted. His eyes were sunken, extremities cold, and pulse hardly perceptible. Vomiting was incessant, and he could scarcely retain medicine or water, and had cramps. He had not passed urine for about eight hours. Sinapism to the epigastrium did not check vomiting, and so a mixture of equal parts of laudanum and chloroform was sprinkled over a piece of lint, which was applied over the pit of the stomach for about five minutes, though not continuously, and it stopped the vomiting. Immediately after this the medicine above referred to was given, and he gradually improved. It was repeated twice at the interval of two hours, and he passed urine and recovered.

CASE 3.—A woman aged twenty-five began to vomit and purge at 6 P.M., when chlorodyne and some other medicine were administered, by which vomiting was checked, but purging continued unabated. The next morning, at 11 A.M., I was called to see her for the first time. She was not able to speak, but could open her eyes when shouted to. She had not passed urine since the attack commenced. The whole body was cold, and there was no pulse; even the beating of the brachial artery could not be felt. Now and then cold perspiration broke out. Two doses of the above medicine were given, but there was no effect. Subsequently some other treatment was adopted by another medical gentleman, but the patient died at about 5 P.M.

CASES 4 and 5.—The remaining two cases had well-marked symptoms, and showed signs of improvement after the first dose; they were ultimately cured by two subsequent doses in one case, and by three in the other.

I may observe here that in all these five cases no food was allowed while vomiting and purging continued. Sinapism to the epigastrium (for checking vomiting) and friction and warm bottles to the extremities were ordered. As regards the medicinal properties of the above-mentioned drugs, I beg to state that the first three are said to be tonic, and recommended in Makhzanuladviya for cholera; cardamom seeds act simply as carminative. Their botanical names and the natural orders to which they belong are as follows:—

Name of drug.	Botanical name.	Natural order.
Jadvari khatai.	Delphinium denudatum.	Ranunculaceæ.
Papita.	Strychnos ignatii.	Loganiaceæ.
Narjili daryai.	Lodoicea seychellarum.	Palmeæ.
Cardamoms.	Elettaria cardamomum.	Zingiberaceæ.

These drugs are mentioned by Dr. W. Dymock in his "Vegetable Materia Medica." Narjili daryai has a very hard kernel, and requires to be filed before it is finely powdered.

It is obvious that the number of cases in which this new remedy was tried is too small to enable one to judge of its value; however, it deserves a further trial.

Oxford.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. GEORGE'S HOSPITAL.

EIGHT CASES OF FRACTURE OF THE PATELLA, PUT UP IN GUM BANDAGES AS SOON AFTER THE ACCIDENT AS POSSIBLE; REMARKS.

THE following cases illustrate the method of treatment of fracture of the patella as at present practised at one of the large London hospitals. It comprises the essentials of treatment of such fractures—rest, relaxation of the quadriceps extensor of the thigh, and apposition of the fragments by direct pressure. It also permits the patient to get about at an early date after the injury, the fractured ends being still retained in good position, and the knee-joint kept extended by means of the gum bandage. We would also refer to the remarks appended to Mr. Rivington's case, where suppuration followed paracentesis of the joint, in a case of simple fracture of the patella.[1]

For the report of the following cases we are indebted to Mr. Allingham, house-surgeon.

CASE 1. (Under the care of Mr. Holmes.)—Thomas S——, aged thirty-five, carman, was admitted on Sept. 7th with the following history. While walking along the street he slipped off the kerb, and in trying to save himself from falling under his van heard something give way with a snap. Attempting to rise, he was utterly unable to use his left leg, so he was brought to the hospital. On admission the left patella was fractured transversely about its middle, the fragments being separated one inch; there was very little effusion into the knee-joint. It was immediately done up in the following manner. The limb having been thoroughly washed, the fragments were brought together with ordinary strong strapping. The centre of a piece of strapping one inch and a half wide, and long enough to encircle the limb twice, was placed immediately above the upper fragment, and the two ends pulled in the direction downwards and backwards, crossed behind the joint, and brought forward to meet upon the tubercle of the tibia. This tends to bring the upper part of the patella down to the lower. The other fragment was treated in like manner; a similar strip of strapping was placed just below the lower fragment, then crossed behind the joint and made to meet above the patella in front of the thigh. Next, strapping, two inches and a half wide, was placed over the front of the patella, each end drawn forcibly backwards, crossing behind the joint, brought forwards again, so that the ends might stick on the front of the knee. (Great care must be taken that none of the strapping slips in the slightest degree.) The limb was then well starched and covered evenly from the level of the base of the little toe to about two inches below the perineum, with two thicknesses of flannel bandage, and this in a similar manner encircled by a coarse muslin bandage three inches in width, strong thick gum being then spread over this. Two more layers of bandage, alternating with two of gum, having been applied, the splint was completed. During this process—or after the fragments were brought together with strapping—the leg was supported by the heel, nothing being placed under the thigh or knee that might tend to bend the joint in the slightest degree; for it is absolutely necessary that the fracture be not disturbed, and that the gum bandage should dry with the leg in a state of extreme extension. During the drying the leg was raised by a block placed under the heel to prevent the wet bandage sticking to the bed; as soon as the outside dried, the limb was placed in a patella junk. (The outer layer of gum takes about four hours to dry, but two days are required for the splint to become firm and hard.)

Sept. 8th.—Splint is drying fast, being elevated in a patella junk. Patient complains of pain in the knee; the toes are not swollen. Temperature normal; pulse 80; tongue clean and moist. Did not sleep well.

10th.—Still complains of a little pain, but much less than it was. Temperature normal; slept well.

14th.—No pain; got up and walked about the ward with the help of crutches.

21st.—Left hospital, fourteen days after the accident.

The patient returned about the middle of October, the splint being quite comfortable. He was told to come back at the end of three months, when the splint will be removed and a leather knee-cap supplied him.

CASE 2. (Under the care of Mr. Holmes.)—William B——, aged thirty-five, a painter, fell five feet and fractured his patella transversely by indirect violence on October 30th. On admittance, the fragments were separated about one inch. The accident occurring near the hospital, he was seen about ten minutes after, and as there was no effusion, the fractured surfaces were brought together with strapping as described in Case 1, and the limb enveloped in a gum bandage.

Oct. 31st—Had a good deal of pain in the knee, which was much relieved by elevation.

Nov. 1st and 2nd.—Still some pain, but not so severe; temperature remained normal; toes warm and not blue or swollen.

6th.—Patient was up but had not put his foot to the ground.

12th.—He left the hospital, thirteen days after the accident, with orders to return in a month.

Dec. 15th.—The splint becoming loose, it was removed. The fracture was in good condition with a quarter of an inch between the fragments. Another splint was then applied and he was told to come back at the end of January for a knee-cap.

CASE 3. (Under the care of Mr. Rouse.)—Arthur M'——, aged forty-six, was brought to the hospital on May 24th with the following history:—Whilst running he slipped on a stone, and, trying to save himself, felt something give way in his knee. The right patella was found fractured transversely, the fragments separated about an inch and a half to two inches, with some effusion into the knee-joint. As this was not considerable, and as the upper and lower fragments of the patella could be placed in good apposition, the limb was put up immediately in gum bandage as described in Case 1. For a few days he complained of pain in the joint, but as he was able to sleep and eat, and as his temperature remained normal, it was not deemed necessary to remove the splint. The pain in this case was greatly relieved by well elevating the limb. On June 2nd he left his bed and was about the ward, leaving the hospital on June 6th, thirteen days after the accident, with orders to come up to be seen every month. In July he presented himself and urged to have the splint removed, as he felt confident the leg was well. This was done, and the upper and lower fragments were found in very good position, firmly bound together with an interval of one-third of an inch. He was ordered a leather knee-cap.

CASE 4. (Under the care of Mr. Rouse.)—Sarah D——, aged thirty-four, pregnant seven months, was admitted on April 28th. While descending some stairs she caught her foot in the carpet and fell down. The left patella was found fractured transversely; no effusion into the joint, fragments separated about three-quarters of an inch, but easily approximated so as to elicit bony crepitus. The joint was strapped and the gum bandage applied at once. That night, and for the next few days, the patient complained of pain, which was greatly mitigated, as in the former, by elevation of the limb.

On May 6th she was about the ward, and left the hospital on the 8th, ten days after the accident. This patient has not been to the hospital since.

CASE 5. (Under the care of Mr. Pick).—Sarah MacP——, aged sixty, while walking along the street fell and struck her knee against the pavement. She was immediately taken home and fomentations ordered by her medical man. On June 29th, seven days after the accident, she came to the hospital. The left patella was fractured obliquely, the line of fracture running from without upwards and inwards, the fragments separated one inch. There was a large quantity of fluid in the joint, and great bruising extending over the front and sides of the joint, spreading also down the leg. Under these circumstances it was not thought advisable to treat this case as those previously described. So the leg was bandaged, including the knee, with a Martin's bandage, as tightly as the patient could bear it, the leg elevated, and an ice-bag placed over the joint. At night she complained of so much pain as to necessitate loosening the bandage, the ice being continued. This treatment was pursued for six days, when all the excessive fluid was found absorbed, and the fragments could be drawn together; the leg was put up in the usual way. She left the hospital on July 23rd, three weeks after admittance.

At the end of September, three months after the accident, the splint was removed. The fragments were in good position, with about one-third of an inch interval; but, as the bond of union was not strong, she had the splint reapplied for another month before commencing to wear a knee-cap.

CASE 6. (Under the care of Mr. Haward.)—Rose W——, aged thirty-nine, married. Two days before admittance into hospital she fell from some steps, and in trying to save herself injured her right patella.

On admission, Feb. 14th, a transverse fracture was found with one inch interval between the fragments, and no effusion into the joint. The fractured bone being placed in a good position, the leg was enveloped in the gum bandage.

Feb. 15th, 16th, and 17th.—Leg quite comfortable; no pain.

18th.—She got up, leaving the hospital on Feb. 27th, a fortnight after the accident.

May 14th.—The splint was taken off. A firm, strong, fibrous band, uniting the fracture with a quarter of an inch between the fragments, existed. Knee-cap ordered.

CASE 7. (Under the care of Mr. Haward.)—Walter C——, aged thirty-three, carpenter. Slipped, catching his foot in a carpet. In falling he heard his knee-cap break. He could not stand, so was brought to the hospital on Feb. 19th. Right patella was fractured about its middle, with an inch and a half interval. As there was no excess of synovial fluid in the joint, the leg was put up at once.

---

[1] THE LANCET, Jan. 24th, p. 154.

Feb. 25th.—Had been up two days, going out on Feb. 27th, eight days after the accident.

On May 19th the gum bandage was removed. Good union and close apposition of the fragments being found, a knee-cap was ordered.

CASE 8. (Under the care of Mr. Haward.)—On March 17th Charles W——, aged thirty-two, drayman, was brought with the following history—viz., that he fell while walking on glazed tiles. On admission the left patella was found fractured, the fragments separated widely, nor could they be seen owing to the amount of fluid in the joint. This evidently was a case for the use of Martin's bandage, applied as in Case 5. After three days of this treatment the fluid was absorbed and the leg encased in gum bandages. The patient got up on March 23rd, and left the hospital on the 25th, eight days after the accident. The splint was taken off on July 2nd, and the fragments were found united by a firm and thick fibrous band, and separated half an inch.

Remarks.—With regard to this method of treatment, there are some points worthy of observation. It is well known that bringing the upper and lower parts of a fractured patella together tends to tilt the fragments so that the posterior edges of the fractured surfaces meet only, leaving an interval between the anterior edges. Now, it is to remedy this displacement that the third piece of strapping is used, the object being to press on both pieces, and so overcome the tendency to tilt. The amount of fluid in the joint is the indication for the method of treatment to be adopted. If the effusion is great, a Martin's bandage should be used for the first few days. On the other hand, a fracture accompanied with no increased secretion of synovia should be done up at once, for if left for only three or four hours there is sure to be considerable swelling. Previous to putting the fracture up in gum bandage it should be borne in mind, after the strapping is applied, to cover the limb in a double thickness of flannel bandage; for, as this is slightly elastic, it allows the leg to swell to a limited extent. Care should be taken, when putting on the muslin bandages, not to apply them too tightly, and as soon as the gumming is finished to elevate the limb. For two or three days after completion of the splint special attention should be paid to the temperature; if this remains normal, the tongue moist, and the toes warm, there is no need of alarm if the patient complains of pain; but should, on the other hand, the temperature rise, or the toes become swollen, cold, or blue, the splint must be immediately removed.

In treating these cases in the manner described quite as good results are obtained, with no more danger to limb or life and with the following advantages. The patient is not confined to bed for six weeks or two months, as he is if treated by Malgaigne's hooks or any other form of apparatus generally used, but can, as a rule, after a few days, say fourteen at the most, go home and undertake any light work. By strapping the fractured surfaces together and not interfering with them for three months it must be apparent that there is more probability of obtaining firm and good union than by those methods of treatment where it is necessary that the fracture should be frequently attended to, and the fragments thereby be more often disturbed; and certainly the method described is much less distressing to the patient. Putting up the leg in gum bandages rather than plaster-of-Paris has these advantages—viz., the splint is much stronger, does not bend or crack as plaster is apt to do, and, lastly, it is a much lighter apparatus.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

CANCER OF THE RIGHT KIDNEY; CONGENITAL ABSENCE OF THE LEFT; NECROPSY; REMARKS.

(Under the care of Mr. F. E. MANBY.)

FOR the following notes we are indebted to Mr. J. W. Batterham, house surgeon.

George W——, aged forty-eight, a painter, was admitted on December 11th, 1884. The patient was a sallow, delicate-looking man, and suffered from dyspeptic symptoms. He stated that for fifteen years he had experienced pain in the right loin, that eighteen months ago he first noticed blood in his urine, and that five months ago his urine was again bloody, this time for three days, but since then he had had several attacks of hæmaturia at irregular intervals. He had lost flesh considerably during the last eighteen months. On the day of admission the urine contained a large quantity of blood and disorganised clot. No cells likely to be of malignant origin were found on microscopical examination of the urine. On passing a sound into the bladder no stone or tumour could be detected, nor was there any blood in the urine after the sounding. Examination of the abdomen revealed a smooth ovoid elastic tumour in the right lumbar and iliac regions, extending slightly into the umbilical region; its rounded margin could be distinctly felt on three sides, but above it appeared continuous with the liver at the level of the ninth rib. The tumour followed the descent of the liver and diaphragm on deep inspiration, and receded with them during expiration. The manipulation of the tumour was followed by the appearance of a little blood in the urine. The question of operation was entertained, but the patient was unwilling to submit to any operative interference. Meanwhile he caught cold, and died of broncho-pneumonia.

Post-mortem examination showed the right kidney symmetrically enlarged, but presenting several small hemispherical bosses on its surface. It measured six inches by four inches and weighed twenty-five ounces. On section it was found to be infiltrated by a mass of encephaloid cancer. It contained no calculi or other concretions. Though a careful and prolonged search was made, no vestige of the left kidney and ureter could be discovered; nor could any trace of the left renal vessels be found, except a slight dimpling of the inner surface of the aorta at the spot where the renal artery would normally have been given off. On further dissection, it was found that the left vesicula seminalis was also absent, although the vas deferens pursued a perfectly normal course. Both testicles and both adrenal bodies were present and normal in appearance. No other abnormalities than those above described were discovered. There were no secondary deposits of the malignant growth. There were no adhesions between the liver and kidney, nor any apparent deficiency of perinephritic fat by which the mobility of the renal tumour might have been accounted for.

Remarks by MR. MANBY.—The mobility of the tumour was a perplexing element in the diagnosis of the case. Dr. W. Roberts states, with reference to renal cancer that the "fixity of the growth is usually a marked characteristic"; and had there been no hæmaturia, as happens (according to the above authority) in nearly half the cases of cancer of the kidney, the tumour would in all probability have been diagnosed as of hepatic origin. The absence of any other ascertainable cause of hæmaturia, and the appearance of blood in the urine immediately after manipulation of the abdominal growth, indicated, however, the nature of the case. The presence of one kidney only, illustrates one of the dangers of nephrectomy—viz., that of removing an only (or the only serviceable) kidney—an error which should be avoided by the use of Mr. Davy's rectal lever as a diagnostic instrument. By compression per rectum of the ureter of the kidney it is proposed to remove the flow of urine from the other ureter into a previously emptied bladder, as is readily demonstrable. This means of diagnosis has been successfully employed by Mr. Davy and others; and I have satisfied myself, by experiments on the cadaver, that the rectal lever will effectually control the passage of fluid along the ureter.

RUPTURE OF THE LUNG AND (?) RUPTURE OF THE LIVER; RECOVERY; REMARKS.

(Under the care of Mr. KOUGH.)

The notes of this case are also furnished by Mr. Batterham.

Eli T——, aged six years, was admitted on Dec. 21st, 1884, having been run over a few minutes previously by a light waggon, two wheels of which were said by a bystander to have passed over the patient's chest. He was sensible, but pale and collapsed. The pulse was small, quick, 168 per minute; respiration was abdominal, short, shallow, 76 per minute. Two hours after admission, when the effects of the shock were passing off, the following notes were taken. "Pulse 160; respiration 72. The short respiratory movements are restricted to the abdomen and left side of the chest. The little patient lies on his right side, with his thighs flexed on the abdomen, and complains of pain, which he locates when asked by placing his hand just above the umbilicus.

resembled one which he had shown to the Society last year, in which there were bands of fibrous tissue enclosing islets of hepatic tissue; he had detected no parasite in the specimen shown by him.—Dr. Bristowe said that he had at first understood that the swollen yellow portion of the liver was the diseased part, but this appeared not to be the case.—Dr. Carrington, in reply, did not suspect the presence of actinomycosis; he did not think that his specimens altogether resembled those of Dr. Price.

Dr. Charlewood Turner showed a specimen of Rupture of the Thoracic Aorta. It was removed from the body of a man aged sixty-four, a labourer, who was seized with collapse of sudden onset and died from syncope the day afterwards. He had frequently suffered from faintness, dyspnœa, and palpitation. The loose stools contained some blood on the day of his admission to the hospital. At the autopsy the arch of the aorta exhibited an L-shaped rupture; the longitudinal rent was situated on the posterior aspect of the aorta. The recent transverse limb of the L-shaped rent passed round the whole circumference of the aorta. The rent led into the dissecting aneurysm, which had a wall of smooth lining membrane, and lay in the same plane as the recent separation of the coats of the aorta. The aneurysm had ruptured into the pericardial cavity, which contained a black blood-clot and some serous fluid. The aorta was atheromatous, but not in the first part; the left ventricle was hypertrophied, and its cavity nearly empty; the kidneys were granular; the cerebral arteries were atheromatous; the lungs were emphysematous. The day before the man's death it was probable that extravasation into the connective tissue of the mediastinum occurred, and the free extravasation into the pericardium probably accompanied the fatal seizure; these extravasations were due to the sudden giving way of the supporting blood-clot as the result of some sudden alteration in the arterial blood pressure. Dr. Peacock had put on record some cases of rupture of the aorta, some of which were of a T shape. In the present specimen the inner and a few layers of the middle coat were torn through in the lower part of the longitudinal rent, and the middle coat was completely rent in the upper part. A second specimen was shown of perforation of the aorta into the pericardium. The case was that of a woman thirty years of age. The arch of the aorta was extensively diseased, of dull appearance, and, in many places eroded with intervening raised areas—probably in different stages of endarteritis.—Dr. Norman Moore remarked on the presence of the cardiac hypertrophy associated with the condition of the kidneys, and said that in nearly every case of aneurysm of the aorta thus associated he had found that the patient was the subject of gout. In a case of hæmorrhage into the pericardium from rupture of an aortic aneurysm, where the kidneys were diseased, he had found gouty changes in almost all the joints of the body.—Dr. Turner said that he had not examined the joints in his case.—Dr. Norman Moore, in reply to a question from the President, said there were many cases of granular kidney in which no gouty changes existed in the joints.

Dr. Parry Price showed specimens of Bony Deposit in the Testes and Epididymis, which were removed from the body of a man aged from fifty to sixty, who was admitted into the hospital in a comatose condition. There was cirrhosis of the liver and enlarged, slightly granular kidneys, cystitis, and two strictures of the urethra; the hard deposit in the testes and epididymis of both sides consisted of typical bone; no healthy glandular tissue could be seen in the testes or epididymis; the vas deferens was healthy. The symmetrical nature of the deposit was remarked on. The changes were probably the result of an old orchitis, following an urethritis, of which the strictures were evidence. He could find no account of any similar case. No cartilage was present in the specimen.—Mr. Alban Doran asked whether there was any suspicion of the disease being of the character of a dermoid tumour. Dermoid tumours of the testes were very different from those which were found more frequently in the ovary. He did not think the specimens were related to the "dermoid class," and Dr. Parry Price agreed with him.

Dr. Colcott Fox showed a specimen of Primary Sarcoma of the left Suprarenal Capsule, with Thrombosis of the inferior vena cava and right auricle, taken from a child aged two years and a half. There was only a history of phthisis on the mother's side, and a possible history of syphilis in the family. The patient was the fourth child, and had always been very fat; there was a cutaneous eruption at the end of the first year, but no snuffles. When first seen, at the age of two years, she was very rickety and of bloated appearance, with a dusky hue about the cheeks, and remarkably hairy, especially about the genitals. For four months there had been enlargement of the abdomen, with a ravenous appetite and great thirst. There was a great deal of sighing. There was no œdema of the lower limbs, nor any specially enlarged subcutaneous veins. A tumour was felt in the left side of the abdomen, occupying the loin, and evidently not the spleen. The bowels were constipated; the urine was normal. Some days after first being seen she had an attack of vomiting, in which lividity and rapid breathing were observed. A similar seizure occurred later on, and the temperature was found to be 102·6°; there was a rapid feeble pulse, but no cardiac bruit could be detected; after stercoraceous vomiting the patient died. At the post-mortem examination the face and neck were swollen, the lips blue, the vulva and clitoris were much hypertrophied, the liver weighed 38 oz.; there was no clot in the portal vein; some dark grumous fluid escaped on removal of the tumour; the left kidney was healthy, but somewhat distorted in shape. The mesenteric glands were the seat of secondary deposits. There was a completely decolourised clot, filling the inferior vena cava and adherent to its walls, and reached along its whole length; it extended to and almost completely filled the right auricle, and projected through the auriculo-ventricular orifice. The uterus and ovaries were large. The tumour was about the size of a cocoanut, and had flattened the kidney; there were areas of hæmorrhage in it; it was microscopically proved to be a large-celled sarcoma. The sections were made by Mr. John Shaw. Thrombosis of the vena cava had been reported by Dr. Moxon in a case of pyæmia with abscesses in the pelvis. In the eighteenth volume of the Transactions Dr. Greenhow had placed on record the case of a girl, aged twelve years, in whom a suprarenal tumour existed. Merkel had described similar tumours. Dr. S. West and Dr. Dickinson had recorded other cases. In Dr. Dickinson's case the gipsy colour without bronzing, the enormous appetite and the vomiting, and other features closely resembled the case now recorded.—Dr. Bristowe said that he had seen a case of primary "cancer" of both suprarenals in a Chinese youth, and thought it was possible in the light of recent investigation that this might have been one of sarcoma.—Mr. Sutton spoke of a specimen of a tumour replacing the right suprarenal capsule in a marmot; the liver and spleen were the seat of secondary growths. This tumour had the structure of the zona fasciculata of the suprarenal body. He had met with similar tumours in a man. He referred to a paper published by Grawitz in Virchow's *Archiv* on the subject of Supernumerary Suprarenal Capsules; tumours having the structure of the cortex of the adrenal were found beneath the capsule of the kidney, and also about the ovaries in the broad ligament. He considered that in the face of such facts we might have to establish a new variety of tumours to include those he had referred to.—Dr. Dickinson spoke of two cases which had been under his observation. In the first case the voice was very gruff and of a bass tone; the words uttered by the precocious infant were very few, but consisted of expletives used by the lowest classes of society; the other characters had been referred to by Dr. C. Fox. The second case had been in the Hospital for Sick Children, Great Ormond-street, and was that of a female child, aged three years, who had also great development of the external genitals, which were studded with large hairs; there was an abdominal tumour having all the characters of a renal tumour, but the memory of the first case he had seen led him to diagnose tumour of the suprarenal body; the autopsy confirmed the diagnosis. In both the cases the relation of the colon to the tumour was rather different from that which usually obtained in renal tumours, for the tumour appeared to be rather above the level of the ascending colon. He thought that this clinical point might establish a distinction of diagnostic value between renal and suprarenal tumours.

Dr. Norman Moore showed a specimen of Tuberculosis of the Kidneys of the Ox with Bacilli. The kidneys were much enlarged, and one completely changed into a great white mass, with hardly any remains of kidney structure except the external lobulation. One lobe of the other kidney had undergone a similar complete change, and elsewhere it showed numerous white nodules. These, as well as the completely changed kidney, showed abundant groups of bacilli, and the bacilli themselves agreed in form, method of staining, and size with the bacilli of tubercle in man. The

Poupart's ligament, and into which the muscles of the abdominal wall are extensively inserted.

Mr. TAYLOR also exhibited a cast of a foot illustrating recovery after Disease of the Tarsus, in which the mid-tarsal joint had been largely involved. The internal cuneiform bone had been removed during the process of treatment, and the resulting cavity was thoroughly drained by a tube passed through the foot. After this was done the improvement was marked and rapid. The foot had been free from any discharge for nine months, and the patient was beginning to use it again.

Dr. SUCKLING showed a case in which Subcutaneous Nodules around the knee, elbow, and finger-joints were present. The patient, a girl aged nine, had had rheumatic fever six months previously; there was a well-marked double mitral bruit, the nodules seemed to be attached to the periosteum and tendons about the joints, and were painful at times.

Dr. SUCKLING also showed a case of Spinal Meningitis which had left loss of the patellar reflexes. The patient, a man aged forty, after being much exposed to cold and wet weather three months previously, had been seized with pains in the back, aggravated by movement; and hyperæsthesia of the feet which prevented him from walking. There was also loss of control over the bladder, and tenderness on percussion over the lumbar spinous processes. After free counter-irritation in the lumbar region of the spine, all the symptoms disappeared except the loss of the knee-jerks. The case was distinguished from one of locomotor ataxia by the absence of (1) characteristic lightning pains, and (2) of the eye symptoms, also by the rapid onset after exposure.

Dr. BODINGTON read a paper based on a visit to Mons. Voisin's wards at the *Salpêtrière, Paris.*

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society took place on Feb. 12th.

Perihepatitis causing Strictures of Bile and Pancreatic Ducts, and Cystic Enlargement of Pancreas.—Dr. BANHAM exhibited a specimen showing strictures of the cystic and common bile-ducts. The pancreatic duct opened into the diseased portion of the common bile-duct, so that both pancreatic and biliary secretions had been shut off from the duodenum, with the effect of causing considerable cystic enlargement of the pancreas and dilatation of the hepatic ducts. The liver was enlarged and indurated, and there were marked evidences of old attacks of perihepatitis. Notes of the case were given. The chief symptoms had been jaundice and distressing itching of the skin, and rapid emaciation. The morbid conditions were supposed to be due to syphilis.

Charcot's Disease.—Mr. CATKIN showed a case of Charcot's Joint Disease occurring in the practice of Mr. A. Jackson at the Sheffield Infirmary. The patient, a joiner, aged thirty-seven, with a previously healthy history, applied at the infirmary some months ago with a painless swelling of the knee-joint. It was thought to be an uncommon state of things at the time, as moist sounds, &c., were to be heard at the apices of the lungs. It was at first diagnosed as hydrarthosis in a tubercular subject. Afterwards, the state of his pupils attracted attention in the out-patient room, and all the commoner symptoms of locomotor ataxia were discovered. The relaxation of the ligaments of the knees was less marked in the right knee.—Mr. ATKIN considered that this case, as well as the one brought forward by him two years ago, effectually negatived the friction traumatic theory. The joint lesion in the first case came on whilst lying in bed with a "nerve cyclone," and in this one the arthropathy preceded the ataxia.

Thoracic Aneurysm.—Dr. PORTER exhibited a case of Thoracic Aneurysm. The patient was an engineman by occupation, forty-eight years of age; there was no history of syphilis or rheumatism. An interesting circumstance in the case was that fifteen years ago the patient received a severe injury to his head by the fall of a trap-door, and a scarf-pin he wore at the time was driven into his chest for an inch and a half. For the last two or three years he had complained of pain behind the sternum, and attacks of dyspepsia and palpitation, and for two or three months of neuralgic pain down the left arm. The aneurysmal tumour was visible to the left of the sternum in the third or fourth intercostal space, and a loud, rough, double murmur audible over it. There was considerable cardiac hypertrophy and high arterial tension, but there was no inequality in the pulse of the opposite sides, or of the upper and lower limbs. There were no marked signs of nervous engorgement or other pressure symptoms. The patient had a troublesome cough, and the respiratory murmur was deficient on the left side, with some dulness and moist râles at the left base.

Treatment of Phthisis.—Dr. HUNT read a paper on this subject. He agreed that the disease was a modern one; and pointed out that the countries most free from it were the northern and colder regions, and he strongly recommended the selection of such countries for the cure of phthisical patients. Dr. Hunt expressed himself very sceptical on all therapeutics as remedial agents, and strongly repudiated the course of certain authorities in recommending them as cures. He had extensively employed antiseptic inhalations, but without any marked success, and was disposed to rely very little upon their potency. Iodoform was another remedy that had been tried, but the results were not such as to warrant him to recommend it in the disease. Dr. Hunt closed his paper by expressing the opinion that in the future the treatment of phthisis would come more under the domain of surgery than it had ever done in the past.

At the meeting on Feb. 26th the following specimens were shown:—

Enlarged Heads.—Mr. B. WALKER introduced two very interesting cases of enlarged heads. The first was that of a man aged twenty-eight, a hawker, with abnormal development of the left side of the frontal bone. The right side of the head measured 10¾ in., and the left 12¼ in., the enlargement being apparently confined to the frontal bone, and causing a decided projection in that region. The condition was congenital, and he had been compelled always to have hats specially fitted. His memory was stated to be remarkably good, especially as regarded objects, persons and places, figures and forms, which he never forgot. The second case was that of a girl aged twelve, and was probably hydrocephalic. As an infant she suffered a good deal in her head, and was considered to have "water upon the brain." The head measured nearly 24¼ in. in circumference. Her intelligence was not impaired; she was very useful at home, but was not so far advanced in learning as others of her age.

Aneurysm of the Aorta.—Mr. LOCKWOOD showed a specimen of Aneurysm of the Transverse Portion of the Aorta which had burst into the left lung. The specimen was from a man aged about fifty, who was admitted into the public hospital in an unconscious condition, with blood flowing from the mouth. He only lived four minutes after admission.

Genu Valgum: Wedge of Bone removed.—Mr. PYE-SMITH showed a Wedge of Bone which he had removed from the Femur of a man with severe Genu Valgum. The specimen was from the right limb, a similar one from the left having been shown at a previous meeting. The limb first operated on was well, the other was healing.

Fracture of Cervical Vertebra.—Mr. PYE-SMITH also showed part of the Spinal Column of a man aged about forty, exhibiting a Fracture of the *Sixth Cervical Vertebra.* The injury had been received in a fall from a dray whilst the man was intoxicated. There was paraplegia and loss of sensation below the umbilicus, except in the distribution of the ilio-inguinal and ilio-hypogastric nerves. There was good thoracic respiration and no rise of temperature. A bedsore began to form within twenty hours of the injury, and the patient died on the fifth day. At the autopsy the cord was softened and congested opposite the fracture, and there was also a softened and ecchymosed portion, with considerable effusion of blood around it, in the lower dorsal region. This latter lesion seemed to have produced the paraplegia, and the later inflammation higher up the fatal termination.

Aural Polypus.—Mr. SIMEON SNELL exhibited a large Aural Polypus. It was of the fibrous variety, and grew from the wall of the meatus. It was only of interest on account of its unusual size.

Mr. ARTHUR JACKSON read a paper entitled "Changed Aspects of Unchanged Truths: The Use and Abuse of Rest." He endeavoured to show that the great truths of physiological and mechanical rest, as laid down by John Hilton in his never-to-be-forgotten and unrivalled lecture on Rest and Pain, were being lost sight of in the theories of the present day. He urged their application in the treatment of fractures, excisions, osteotomies, and in that of wounds; and the more or less complete reform of our present mode of treatment.

peptonised foods, bile, feeding by the nose or rectum, and forced feeding are all considered under the head of Aids to Digestion. A page is devoted to stimulants to digestion, which include condiments, bitters, tonics, acids, alkalies, and stomachic sedatives. The arrangement of the matter in this section appears to us to be open to criticism. Unless the context be closely kept in view the author might be understood to imply that forced feeding, and feeding by the nose or rectum, were aids to digestion. Again, it is perhaps not strictly correct to regard alkalies and bismuth as stimulants to digestion. These, no doubt, are trivial objections; but we think it would add to the orderly arrangement of the work if slight alterations in this regard were made in future editions. Amongst the best chapters in the book are those on Pneumatics and Topical Pneumatics. The term "pneumatic" in therapeutics is not in very common use; it was employed by Pereira to signify therapeutical agents which influence the functions of respiration and the formation of heat. Speaking of the work as a whole, it must be pronounced as sound and good, though in our opinion somewhat too diffuse. This is, however, partly compensated by the increased readability which it entails. Had the work been more compressed the student of it would have saved time, though possibly have lost pleasure. But the book is written for those—and we suppose there are such—to whom a little leisure is not yet unknown.

INDIAN HEALTH STATISTICS.

No. I.

THE twentieth annual report of the Sanitary Commissioner with the Government of India shows a satisfactory state of the public health during the year 1883. The average strength of the European troops for that period was 55,525, the admissions into hospital from them were in the proportion of 1336, the deaths of 10·83, the invaliding of 32·66, and the mean daily sick of 62·85 per 1000, being all lower than in the preceding year; the death-rate, indeed, is the lowest recorded in the last fourteen years. The sickness and mortality were distributed in the three Presidencies as follows:—

Ratio per 1000 of Strength.

Average strength.	Admitted into hospital.	Died in India.	Invalided to England.	Mean daily sick.
Bengal, 34,079	1453	11·21	30·59	65·9
Madras, 10,493	1013	10·19	32·70	55·6
Bombay, 10,943	1249	10·50	35·03	57·5

The admissions in all the three Presidencies were considerably lower than in 1882, and the deaths also show a reduction, except in Bombay, where there was a fractional increase. The invaliding from Madras and Bombay and the mean sick in Madras were higher than in the preceding year. Bengal still furnishes the highest and Madras the lowest ratios of admissions and deaths, but the reduction in the death-rate has been much greater in Bengal than in the other two Presidencies. Paroxysmal fevers cause about one-third of the admissions into hospital in Bengal and Bombay, but Madras enjoys a comparative exemption from them. In the two former the cases were in the ratio of 434 and 412 per 1000, while in Madras they amounted to 112 only. They are not the cause of much mortality. The disease which gives the highest death-rate in all the Presidencies is enteric fever. The mortality by it in 1883 was 2·52 in Bengal, 2·86 in Madras, and 1·55 in Bombay. For the whole force the admissions were 7·7 and the deaths 2·40 per 1000; consequently 31 per cent. of the cases terminated fatally. Omitting stations where only one case occurred, the proportion of deaths to cases ranged between 8 per cent. at Kurrachee and 66 per cent. at Gwalior Fortress. The influence of age upon the death-rate by enteric fever was shown by the mortality among men under twenty-five being 4·34, from twenty-five to twenty-nine being 1·50, and at thirty and upwards 0·70 per 1000. In like manner, as regards length of residence in India, the death-rate in the first and second years of service was 4·98, third to sixth years 1·55, and seventh to tenth years 0·55 per 1000 living in each period. Of 44 cases at Lucknow, 35 occurred in the Derbyshire regiment, "which arrived in India from Egypt on 24th November, 1882, and which was principally composed of very young soldiers." The months in which enteric fever prevailed most were April to September, the admissions into hospital having been 340, as against 89 in the six months October to March inclusive. "With regard to the etiology of the disease, no positive results of any value were arrived at." At Bangalore there was strong evidence of its connexion with the unsatisfactory nature of the water-supply, but in many of the other stations it could not be traced to any common cause. The European troops were remarkably free from cholera, the admissions having been only 1·4 per 1000 in Bengal, 1·8 in Madras, and 1·4 in Bombay, with the corresponding death-rates of 0·94, 0·95, and 0·82 per 1000. In Bengal the stations affected were Allahabad, Benares, Gwalior Fortress, and Chunar; in Madras, Secunderabad and Kamptee; and in Bombay, Ahmednugger and Deolali. Next in frequency to enteric fever as the cause of death in 1883, apoplexy and sunstroke rank in Bengal and Bombay and hepatitis in Madras; the ratio of the former was 1·32 and 1·10, and of the latter 1·72 per 1000 of the strength.

Venereal diseases have been a cause of much inefficiency in all three Presidencies, the admissions into hospital having been in Bengal 281, in Madras 289, and in Bombay 218 per 1000 of the strength. The cases of primary syphilis returned in each Presidency were 88, 111, and 63 per 1000, and of secondary 25, 22, and 21 per 1000.

The mortality among the women was in the ratio of 21·28, being higher than in the preceding year, but under the average. The most frequent causes of death among them were childbirth and abortion and phthisis. Among the children the death-rate was 46·88, being considerably lower than in the preceding ten years. Diarrhœa, dentition, convulsions, and anæmia were the most fatal diseases.

The average strength of the Native Army of India during the year was 114,830. The admissions into hospital amounted to 923, the deaths from all causes to 14·31, the discharges by invaliding to 28·12, and the constantly sick to 31·3 per 1000 of strength. These ratios are all much below the average; the admissions and mean sick are considerably under, but the deaths 3·43 above, those of the European troops during the same period. The sickness and mortality in the three Presidencies respectively were as follows:—

Ratio per 1000 of Strength.

	Admitted.	Died.	Constantly sick.
Bengal	955	13·98	32·0
Madras	737	13·51	27·5
Bombay	994	14·98	34·7

This table shows the Bombay Presidency to have been the most unfavourable to the health of the native troops. Paroxysmal fevers were the most prevalent diseases in all the Presidencies: but, as was the case with the European troops, gave rise to a considerably lower proportion of admissions in Madras than in the other two Presidencies. The cases of intermittent fever were 398 in Bengal, 389 in Bombay, and 271 in Madras per 1000 of strength. The Native troops continue to show a marked exemption from enteric fever, only eighteen cases and five deaths having been returned from the whole army. Cholera did not prevail to any extent in Bengal or Bombay, but in Madras the admissions amounted to 6·2 and the deaths to 2·92 per 1000 of strength. Its prevalence was confined to Secunderabad, Kamptee and Raipur, Vellore and Trichinopoly, and among troops on the march, and two fatal cases occurred at Toungoo in Burmah. Twenty-five cases and fifteen deaths occurred in the Hyderabad contingent, and of these ten, with three deaths, were in the 2nd infantry at Ellichpur. The most fatal diseases among the Native troops were those of the respiratory system, the deaths by which amounted to 3·20 in Bengal, 4·62 in Bombay, and 1·66 in Madras per 1000 of strength. The prevalence of venereal diseases in the Native army offers a very marked contrast to that in the European force, the admissions having been only 31·6 per 1000, as against 270·3. The usual summary of the sanitary sheets of the Native Corps is given. They indicate a considerable amount of overcrowding and of insufficient ventilation, and there seems at many of the stations abundant room for improvement of the drainage and of the general sanitary arrangements.

The most urgent of these is a shortening of the period during which the protection extended to persons placed in an asylum under "urgency certificates" is to be withheld. Practically there is little fault to find with the safeguards provided for the protection of ordinary cases which, after this Act comes into operation, will be submitted to the supervision of a County Court judge, a stipendiary magistrate, or a justice of the peace; instead of being rushed secretly into an asylum without any sort of check on the *bona fides* of the person making the "order." Henceforth orders will, in the regular way, be made by magistrates only. There is, however, a dangerous loophole left for wrong-doing by the adoption of the method of incarceration by "urgency certificates." In itself, this method, which has been borrowed from the Scotch system, is admirable, and will fulfil many useful purposes; but it would manifestly be destructive of the principle of the measure to permit a weak-minded or eccentric person to be put away in an asylum with a single medical certificate, and left in the midst of lunatics for seven days before a petition were presented to a magistrate. Yet this is the effect of the Bill as printed! Again, a report is to be made to the Commissioners a *month* after the admission of a patient to an asylum. Why a month? If a month, and then so much longer as may suit the convenience of the Commissioners in Lunacy, are allowed to elapse before the lunatic is visited, obviously great harm may be done. The *idea* of the Bill is to provide that in *all* cases of admission to an asylum there shall be a special visit to the new inmate within a reasonable time after his reception. This is an excellent measure, but it is absolutely necessary that the visit should be paid much more promptly than at the end of a month, *plus* so much longer time as may be implied by "as soon as conveniently may be." As the Bill is drawn, it may very well happen that two months or more will elapse before the visit which is to act as a safeguard is paid, and long before that time the new inmate may be hopelessly insane. In the case of a patient admitted on an "urgency certificate," it is, as we have said, imperative that the magistrate should interfere in less than seven days. A very little reflection must suffice to make it plain that the danger of wrong-doing will be rather increased than diminished under the proposed Act, unless the powers given under the urgency clause are very carefully guarded.

Speaking generally, the aims of the Bill are good, and not only well directed, but thoughtfully and carefully carried out. Too much, however, is left to the Commissioners, who are assumed to be immaculate, whereas it should be borne in mind by the Legislature that the need for reform has to a large extent arisen out of the careless and perfunctory manner in which the Commissioners have hitherto discharged their duties. If the Commission had not been largely composed of men trained in the evil ways of the asylum-system, and very little in earnest for the interests of the insane, the laws already in existence would have sufficed for the protection of both the sane and the insane. Laws are made for those who either themselves do amiss, or by their error or apathy allow others to offend against the welfare of society. It is indispensable that the most stringent precautions should be now taken to keep the Commissioners up to their work, and to compel them to discharge the obligations of their office in no perfunctory fashion. Let those who doubt this only reflect on the way in which the provision for the scrutiny of certificates by the Commissioners has been carried out. As a matter of fact, it has been the boast of the Chairman of the Commission that extremely few certificates have been found to be defective. What does this mean? Simply and plainly that the Commissioners have not troubled themselves to look beneath the merest surface technicalities. For example, if in filling in a form the certifying person chanced to omit a statement in some blank space of the vocation of the alleged lunatic, he would be called to order; but if he filled another blank space with the veriest rubbish in the way of evidences of insanity, the Commissioners cared nothing for that palpable fact. Unless something be done to make these gentlemen understand that they are to do more than mere clerks' work, the provisions of the Act will fall flat. Let anyone who knows the working of the Commissioners' office at present ask himself what is likely to be the practical result of a provision such as this: "In the case of a private patient in an asylum, the Commissioners, after receiving the report [that is, the report to be sent to them by the medical officer of an asylum at the expiration of one calendar month after the reception of a private patient], shall either make arrangements for a visit being paid, *as soon as conveniently may be*, to the patient therein named by one or more of the Commissioners, or," &c. Beyond question, in as many cases as possible the Commissioners will content themselves by referring the matter to the committee of visitors of the asylum, as the Act allows, and for the rest, "as soon as conveniently may be" will mean anything from a month to three months. Probably it will amount to this, that at the next routine official visit to the asylum the Commissioners who chance to go will be charged to inquire for the patient named in the report, and his or her name will perhaps have two ticks on the list instead of one. If any good is to be done by the passing of this Bill, failure through official neglect must be guarded against at every point. Nothing can safely be left to the Commissioners in Lunacy, and unfortunately much has been left to them, with the gravest peril of reducing the Act to the level of a new incumbrance of the statute book. The provisions throughout are far too permissory in their character. They should order where they now simply allow. This is especially necessary in all that relates to the main purpose—namely, the protection of the alleged insane.

The effect of the measure as regards the gradual superceding of the private-asylum system is, we think, likely to be satisfactory. The Secretary of State can enforce the provision of sufficient accommodation for both pauper and non-pauper cases; and the interest of local financiers will be to receive private patients into public asylums because the profits made in this way can be applied to the relief of the rates by defraying other costs of the asylum. This appeal to the commercial instinct may doubtless be trusted to produce sound fruit. It is much to be regretted that the care of the "sane or insane" cannot be placed on an equally practical footing with respect to the discrimination between suitable or unsuitable cases. Unfortunately, when the committees of public asylums become *de facto* themselves private asylum keepers, making a profit out of every nedical profession would understand by medical science, ut preferred to be treated by the representatives of medical system which is ignored by every University of Europe and by scientific men generally, and the chief representatives of which in England have fundamentally changed their ground. But where our contemporary has gone farthest wrong is in supposing that there is an alarming increase in the frequency of such deaths as that of Lord CAIRNS as compared with the palmy days of bloodletting. No mistake could be greater. The mortality of such cases has been immensely reduced by improvements in modern treatment, and especially by the leaving in the veins of the patient the large quantities of blood which used to be "drawn," as our new censor says. One physician alone, the late Dr. J. HUGHES BENNETT, has recorded 105 cases of *uncomplicated* inflammation of the lungs *without one death*, though many of the cases were severe, involving the whole of one lung in fifteen and both portions of lungs in twenty-six cases. His system of treatment, now generally followed, is described by himself as "treatment by restoratives, directed to further the natural progress of the disease and supporting the vital strength." He entirely avoided "drawing" large quantities of blood, under which the mortality was certainly infinitely greater. We cannot answer for the treatment pursued in Lord CAIRNS' case. It is quite possible, in the dilapidated and demoralised state of homœopathy, that it did not differ from that practised now by most sensible physicians. The fatal result may have been due to the occurrence of a sharp pulmonary congestion or a pneumonia in a constitution by no means vigorous or healthy, and worn by the labours of an anxious profession and position. But one thing we will venture to say without hesitation, that the omission of phlebotomy was not a subject for censure, and that our contemporary will have to find other cases than that of Lord CAIRNS on which to revive a practice so questionable as the "fashion" over the disappearance of which he seems to sigh, and which, like many other fashions, is generally more honoured in the breach than in the observance.

◆

THE lecture on the Sanitary Condition of our Homeless and Nomadic Populations, delivered by Dr. RICHARDSON on Saturday before the Association of Sanitary Inspectors, has struck a chord which has caught the attention of the people in a very remarkable way. It is one of the often-expressed sayings of the author of the lecture that many of his efforts which have gained most public favour have been those which have cost him least trouble and the *smallest* amount of preparation. The lecture opened with an intimation that the services of the sanitary inspectors might be extended with good purpose and effect to the inspection, under skilled direction, of the condition of the people who live without any fixed home. The people thus named were then divided into three classes. The first, the vagrant class, who have no home of any kind, who sleep anywhere, and get food anyhow. The second, the itinerant trade and showman class, who wander about the country in vans, using the van as the living and sleeping house, as well as the storehouse. The third, the pure nomadic class, who still live altogether under canvas—tent-dwellers proper, or gipsies. The conditions of health of these three classes were then compared and contrasted *inter se*, and, by inference, with the members of the ordinary community. To the vagrants a life of a truly unhappy and worthless kind was accorded, but it was indicated that with all their misery they and theirs were less subjected to the decimating zymotic diseases than the members of the industrious populations aggregated in large cities and towns. It was further pointed out as a singular fact that these vagrants wandering to and fro amongst the people, wearing the cast-off and often infected clothing of the people, and occupying common lodging-houses in which the most simple hygienic rules prevail, rarely carry about with them any of the contagious diseases, and rarely suffer from them. The same rule was to a certain extent true in respect to the people who travel and live in the vans, but these are *much more* subjected to other diseases, induced even in the midst of nature, "under the canopy itself," when they begin to shut themselves and their families up "in a travelling experimental room." They then become anæmic and scrofulous, and are affected with consumption of the lungs from a rude and unscientific, though practical, synthesis of that formidable destroyer. As to the true nomads or gipsies who continue still to live in tents, their fate is indeed singular, in so far as the lecturer's observation extended to them, observation which seems to have won *the special attention of hearers and* readers. Dr. RICHARDSON said that in his early professional life, when he was associated in practice with the late well-known Dr. ROBERT WILLIS of Barnes, he had under his care for some months, on Barnes-common, a gipsy lad living in a tent, who had sustained an injury to the spine, and that during this long attendance he had gathered a number of facts relative to the gipsy life, and had learned a little of the language of this singular Indian trail, some words and sentences of which he still remembered and explained. From this and later sources of information he came to the conclusion that the gipsies, perhaps comparatively short-lived—although there were exceptions to this rule,—are remarkably free, so long as they remain in the tent, from the spreading diseases of the community at large. They seemed in this primitive condition to know nothing of small-pox, though little protected by vaccination, and he had never met with one of them pitted with small-pox. In 1850-51 the gipsies on Barnes-common were surrounded with cases of scarlet fever in the neighbouring places, but they all escaped, although they took no precautions, and in fact were absolutely ignorant or indifferent about the matter. More curious still was the statement of the lecturer that he had failed to find a gipsy man, woman, or child in the pure nomadic state who showed evidence of syphilis, either in its primary, secondary, or tertiary stages, and he referred to the perfect condition of their teeth as a corroboration of the truth of this noteworthy observation. When the nomadic gipsy changed his mode of life, when he settled in cities and towns, and so came "under the influences of a higher and more cultivated civilisation," then, doing at Rome as Rome does, he gets what Rome gets. But in his primitive state he seems to escape this, the most corrupting scourge of the human family in its more advanced social life. Altogether, the lessons derivable from the lecture were that poverty of itself, unless pushed to absolute famine, had nothing to do f the egg, as helenina had done. Korab found that a few rops of a solution of helenina immediately killed the rganisms in ordinary infusions, and also in cultivations of the tubercle bacillus. While the writer was working with helenina in his laboratory, he noticed that the bad odours usually present in the vicinity were replaced by the aromatic smell of the drug, due to the washings thrown away. He also noticed that insects, which were commonly very numerous, were at that time absent; even the mosquitoes were kept away from the whole house during the months in which they specially abound. The drug has proved most valuable in surgery as an antiseptic when carbolic acid and other agents had failed. It has been successfully given internally in malarial fevers, tubercular, infantile, and catarrhal diarrhœa; and it is expected to prove an excellent substitute for carbolic acid in the Listerian system of aseptic surgery. The dose is about a third of a grain in pill or mucilage, and the price about a penny a grain.

THE FAVERSHAM JOINT HOSPITAL BOARD.

COMBINATION of sanitary authorities for the purpose of providing infectious diseases hospitals has so many advantages that the system has been largely favoured by the Local Government Board. The scheme involves but a comparatively small increase of cost over a hospital provided by a single authority, for one site, one boundary wall, one set of buildings for ambulance, laundry, disinfecting, and mortuary purposes suffice for two authorities, just as it does for one only; and even as regards the ward-pavilions, only some increase in the number of beds, and not of the buildings, is, as a rule, needed. Some time since, on the application of the urban and rural authorities of Faversham, and after public inquiry at which all parties seemed unanimous, the Local Government Board issued a provisional order forming the two authorities into a joint hospital board. From that moment, however, dissensions appear to have sprung up; disputes occurred as to the site and the character of the buildings, and at last the joint board suspended its meetings, having in the first instance applied to the central authority to be dissolved. But the board having been formed with the approval of Parliament for a definite purpose, the Local Government Board decline to sanction the dissolution except on the definite understanding that each authority will singly perform its duty in the matter of providing means of isolation. No such guarantee appears to be forthcoming, and the whole matter is at a deadlock. This is to be regretted. Both authorities have a considerable population among the labouring classes, who, when infectious disease appears in their homes, have no proper means of accommodation for the sick, and are utterly without such means as would suffice to stay the spread of infection. The elections which are about to take place as to local affairs may perhaps set the matter again on a proper footing, and thus the two authorities may be spared from acting without proper judgment in regard to a step which is of considerable importance to the health of their respective districts.

TRANSFUSION OF BLOOD.

THE public mind has been much astonished and bewildered during the past few weeks by the reports, through the general press, of certain experiments on transfusion of blood said to have been carried out at Denver, Colorado. The popular mind has been astonished and bewildered many times before now on the subject of transfusing restoratives into the circulation of men and animals. The operation starts, indeed, in mystery. Æson, the father of Jason of the Golden Fleece, becoming infirm, Medea, after drawing the blood from his veins, refills them with a potent fluid, and the old man, so runs the fable, rejuvenates. Libavius of Halle, in the early part of the seventeenth century, improves on this fable by suggesting the actual transfusion of blood. Christopher Wren, in the eighteenth century, gives the idea more distinct form; and Richard Lower, Edmund King, and Denis actually bring it into practice, with such effect that the world, startled by the first results and filled with admiring wonder, soon turns round, in disappointment at failure, and lets the Pope prohibit the operation in all parts where his mandate was law. Over and over again the wonder has, nevertheless, revived. Early in this century, Professor Harwood of Cambridge revivified a pointer that had been bled, as it seemed, to death by transfusing into it the blood from a sheep. Later on in the century Dr. Blundell made some remarkable experiments precisely similar in character, and now we have the same retold in a new dress, either by repetition of mere narrative or by repetition of experiment—which it is difficult as yet to say. Of the report going the round of the press it is quite impossible, at present, to speak with any certainty. The account may be nothing more than a piece of clever writing based on an imperfect knowledge of previous researches. It may be the account of some experiments similar to those we have described, but reported with more of enthusiasm than accuracy. We cannot tell. All we can say is that the absence of technical mode of description, some errors of detail, and the absence of reference to all previous research on the subject, together with the notice of many proceedings which according to our present knowledge would destroy the value of transfusion as a means of restoring suspended life, make us most cautious in accepting any part of the statement until it is corroborated by other and more trustworthy evidence.

FRUIT AS AN ARTICLE OF DAILY DIET.

ONE of the most salutary tendencies of domestic management in our day is that which aims at assigning to fruit a favoured place in our ordinary diet. The nutrient value of such food, in virtue of its component starchy and saccharine materials, is generally admitted; and while these substances cannot be said to equal in accumulated force the more solid ingredients of meat and animal fat, they are similarly useful in their own degree, and have, moreover, the advantage of greater digestibility. Their conversion within the tissues is also attended with less friction and pressure on the constructive machinery. The locally stimulant action of many subacid fruits on the mucous membrane deserves mention. Its control of a too active peptic secretion, and its influence of attraction exercised upon the alkaline and aperient intestinal juice, are points of more than superficial importance. To this action further effects, which aid the maintenance of a pure and vigorous circulation, are indirectly due. Thus it follows, on the simplest principles of physiology, that other essential organs, such as the skin and kidneys, are relieved by the transference of part of their excretory function to the bowel, and act with greater ease, the general vascular system is lightened by this regulating drain, and its faculty of absorbing the waste products of food and work is encouraged in proportion. Almost all persons in fairly normal health may partake of sound and ripe fruit in greater or less amount. Except in certain cases, indeed, there is practically no exact limit to its consumption under these circumstances. Among such exceptions may be noted the gouty and rheumatic diatheses. A tendency to diarrhœa or a dysenteric history obviously forbids the free or frequent use of fruit. Saccharine diabetes, or nervous conditions in which it is apt to appear, are similarly antagonistic—at all events where any but the non-amyloid fruits, such as nuts, are considered. Dyspeptic stomachs, on the other hand, are usually benefited by a moderate allowance of this light and stimulating fare. It must be remembered, moreover, that every fruit is not equally wholesome, let the digestion be as powerful as it may. Nuts, for example, consisting as they do, for the most part, of condensed albuminoid and fatty matters, cannot compare in acceptance, either by the palate or the stomach, with other more succulent kinds, even though they contain in the same bulk a far greater amount of nutriment. A little of such fruit is enough for digestion, and that little is best cooked. Nevertheless, if we take fruit as a whole, ripe and sound of course, and consider its variety, its lightness and nourishing properties, whether eaten alone or with other food, and its cheap abundance, we cannot hesitate to add our voice in support of its just claims on public attention. In former articles we have shown why vegetable produce of all kinds should enter largely into the food of children. Well-chosen fruits are consequently for them as safe and beneficial as agreeable.

THE GENESIS OF CANCER.

A marked increase in the death-rate from cancer during the latter part of the present century has for some years occupied the minds of several well-known pathologists in endeavours to reveal its cause. There is a pretty general agreement with regard to this disease that it is prone to arise out of prior morbid states which do not appear to be directly or necessarily related to it. It is evolved as a successor to innocent tumours, or in the track of an old inflammatory lesion. It rises apparently *de novo* out of mere senility or exhaustion of tissue, its permanently rudimentary type representing the best efforts of wearied nature to make good the daily wear of more perfect structures. On the other hand, cases occur in which, without impairment in any visible degree of vital power, the energy of some local irritant appears to master so completely the normal process of growth as to maintain its elements in the exuberant imperfection of the malignant tumour. Manifestly the same irritant acting on weak tissues is still more likely to work out its pernicious consequences. If we admit, therefore, as we consistently may, that tissue exhaustion, the result of toil, anxiety, or privation, and whether inherited or directly induced, affords a sufficient basis for the development of cancer, we need not look far into the history of our laborious age to find an explanation of a rise in its death-rate which at first may seem to be anomalous.

WELL WATER AT ENFIELD.

A curious conflict of opinion has occurred in connexion with certain proceedings having for their object the closure of a surface well in the district of the Local Board of Enfield. Dr. Ridge, the medical officer of health, found the water suspicious from a chemical point of view, and still more suspicious because of the nature of the surroundings of the well. On this, proceedings were taken to secure the closure of the well; but the owner in the meantime procured an analysis by Dr. Tidy of water which professed to be that of the suspected well and of another well mixed together. The chemical results were all that could be wished, and the magistrates dismissed the case. The owner was then told that fresh samples would be taken, and this having been done, the analytical results were found not only to differ from the preceding ones, but, curiously enough, the water exhibited the presence of iron. In view of this, further samples were taken in the presence of several people, and this without any notice to the owner until the arrival of those who were prepared to take the water away with them. This time the analyst found chlorine equal in quantity to 18·45 grains of common salt in every gallon, 17·5 grains of nitric acid as nitrates, and no iron. The absence of iron in this sample points to the intentional addition of that substance with a view to a temporary purification of the water by oxidising or precipitating organic matter. The well in question is 16 feet deep; it lies in a district which has sewers with "open joints," and which have, in consequence, fouled the gravelly soil in which the well is sunk. Several of the house and closet drains were also recently found to be leaking through such joints. These circumstances alone amply suffice for the condemnation of the water-supply, and it is a matter of wonder how people can endeavour to show by chemical analysis that a water derived from a soil thus subject to the constant risk of pollution is really fit for domestic purposes. The freedom of individual samples from any indication of the surrounding contamination is a matter that should have no weight beside the fact that the source of the supply is one subject to constant risk of pollution. In this case, however, chemistry also came to the aid of the medical officer of health when the sample dealt with was collected under circumstances which were above suspicion.

CHILDREN IN WORKHOUSES.

The care, treatment, and nursing of children in workhouses is a subject which at the present time calls for more attention at the hands of Local Government Board inspectors and the philanthropic public. After due allowance for the low physical standard of such children, and for their congenital tendency to disease, the excess of mortality that prevails among them is a subject that urgently demands inquiry and action. Inquiry, because Local Government Reports are silent upon the subject; and action, because much of this excess of mortality is assuredly preventable. It is only now and then that facts come to light helping us to call attention to the health condition of these unfortunate children; this makes it all the more necessary not to miss such opportunities. It appears from the last two weekly returns of the Registrar-General, that during the fortnight ending on the 4th inst. no fewer than fifteen children, most of them illegitimate, died from measles in the Camberwell Workhouse, Gordon-road, Peckham. It will be interesting to learn the number of infants in this workhouse, the number attacked by measles, and also whether this startling mortality will be the subject of a Local Government Board inquiry, with a view to ascertaining the kind of treatment and nursing which workhouse children receive on the occasion of such an outbreak of epidemic disease as that now prevailing in the Camberwell Workhouse.

MAD DOGS AT LARGE.

The inhabitants of Sheffield seem to have been lately thrown into a state of consternation owing to mad dogs wandering in the streets. It is reported that special precautions have been taken by the police, and many dogs destroyed. These precautions are praiseworthy in themselves, but we doubt if they will prevent a recurrence of the danger. There can be no doubt that every dog roving at large, unattended, and "without visible means of subsistence," should be arrested as a rogue and vagabond, but the wholesale destruction of these waifs and strays seems unnecessarily severe. What we would suggest is that the number of places of refuge, or "dogs' homes," be extended. Greater facilities would then be given for watching suspicious characters, and for owners to claim their lost property. But these are cases which require peremptory treatment. If a dog is mad, it is worse than valueless to its possessor, whilst it is dangerous to every living being with whom it comes in contact. This might afford some reason, perhaps, why policemen should be armed with revolvers. It is not always easy, however, for the laity to tell whether a dog is the subject f rabies, or merely gifted with vicious propensities. The ecessary knowledge too often only comes of experience, nd the vagrant cur runs fancy free until it has fleshed ts envenomed teeth in some hapless passer-by. Save n a few isolated cases, where canine madness first shows itself in a fortuitous and unprovoked outburst of ostility towards an unsuspecting individual, the premonitory symptoms are sufficiently marked to arouse suspicion and point to danger. Restlessness, loss of appetite, and perversion of the affections are amongst the number. It is not feasible to educate the public in these matters by practical demonstration, but much may be done by way of warning and advice. A code of instructions might be drawn up and circulated by the local authorities, which would be of incalculable value to the community. It may be contended that such a procedure would arouse needless alarm, and condemn many an unoffending dog to a premature death; but against such an objection is the certainty that a number of human lives would be spared the perils of a terrible disease.

INTERNATIONAL HEALTH EXHIBITION.

DR. FELICE SANTINI, medical officer of health of the Royal Italian Navy, who was appointed by the Italian Government commissioner to the International Health Exhibition, has just published his report to the municipality of Rome.[1] He draws special attention to the excellent organisation of the Metropolitan Asylums Board, and the work done by them and the St. John Ambulance Association, and gives illustrations of the various ambulance carriages and stretchers used by these associations, together with a map showing the hospitals in connexion with the Metropolitan Asylums Board and diagrams of the hospital ships *Atlas*, *Endymion*, and *Castalia*, which are moored in the Thames. Dr. Santini was much impressed with the excellent idea of forming a hygienic library in connexion with the Exhibition, and brings to the notice of his Government and the municipality of Rome the services of Mr. Carl A. Thimm, the librarian, who so efficiently arranged and catalogued the voluminous publications contributed by Italy.

VOLUNTEER MEDICAL STAFF CORPS.

THIS corps, although enrolled only on April 1st, put in an appearance at the Brighton Review. Two companies, about fifty strong each, paraded at Wellington Barracks on Good Friday morning in full marching order, and, taking train at Victoria, accompanied the marching columns. No. 1 Bearer Company, under the command of Surgeon-Major Cantlie and Acting Surgeons Leech, Fletcher, and Willett, accompanied No. 7 column, under the command of Col. Sir Lloyd-Lindsay, V.C., and billeted at Burgess-hill. No. 2 Bearer Company, under the command of Surgeon-Major Norton and Acting Surgeons Huzzey and Raw, accompanied No. 2 marching column, and billeted at Newick. On Saturday the companies followed the troops over the downs, and had some rough work with the waggons. The ambulance waggons of No. 1 Bearer Company were blocked for three hours by a transport waggon, which had broken down on a narrow road over the hill. The bearers carried the stretchers over hill and dale for four miles to keep touch with the troops, and only by a forced march were they able to return to pick up their waggons and join the troops in the march into Brighton. No. 2 Bearer Company had to take the horses out and pull the waggons up the downs. At the headquarters of the corps at Brighton a temporary hospital of eight beds was opened, and as many as fifty-three patients were treated between Saturday night and Monday morning. The appearance of the new corps at the march past on Monday was the subject of much congratulation and cheering. The Duke of Cambridge, after the march past, rode up to the head of the column and complimented the corps on its appearance and efficiency. Surgeon Cross, Grenadier Guards, acted as commanding officer, and Surgeon Pearse as his staff officer. Lieutenant McLure acted as adjutant during the march. On the day of enrolment of the Volunteer Medical Staff Corps, an inauguration service was held at the Chapel Royal, Savoy, by the Rev. R. Westhorpe, Warden of Charing-cross Hospital and Chaplain of the Corps. About 180 attended.

THE METROPOLITAN BOARD OF WORKS AS A THEATRE LICENSING AUTHORITY.

THE Metropolitan Board of Works has politely asked the Lord Chamberlain whether he does not think it would make a better licensing authority than he has proved himself, and offered, "if his lordship agrees with this view," to take over the duty. We shall be curious to hear what the Lord Chamberlain thinks of this proposal. If he is wise he will hasten to wash his hands of the business. Meanwhile, will the Metropolitan Board of Works do the work better? And how about the licensing of stage plays? Does the Board propose to take that over also?

REPORT OF THE BERLIN HYGIENIC EXHIBITION.

WE have received a copy of the introduction to the first volume of the Report upon the German Health Exhibition, held at Berlin in 1883. On the close of the exhibition the task of editing this Report, which should survey the whole nature and scope of the exhibition, was placed in the hands of Dr. Paul Börner, who has prefixed to it an introduction detailing the steps taken to promote the exhibition, which was completed and ready for opening when destroyed by fire in 1882. Within twelve months the building was reconstructed on an improved plan; and a description of the building is given, with a brief history of the exhibition from its opening to its close. From the table of contents to the volume it is seen that the descriptive articles of each department are contributed by experts; and the work should therefore have a special and permanent value.

SHOULD AN INQUEST BE HELD?

MR. H. GOTOBED, the Cambridge borough coroner, recently held an inquest on a woman who had died suddenly of heart disease, and gave as his reason for so doing that about two years ago Lord Chancellor Selborne admonished a coroner for neglecting to institute an inquiry into the cause of death of a person found dead in bed. Lord Chief Justice Jervis held that, unless there was reasonable ground of suspicion that the person came to his death by violent and unnatural means, there was no occasion for the interference of the coroner. On the strength of the report of the recent inquest, we fail to see the discrepancy between the legal authorities cited by Mr. Gotobed. A person being found dead in bed, the presumption is that death arose from natural causes; but it would never do to grant a certificate on such wholly insufficient grounds. If, on the other hand, a person was known to have suffered from heart disease, and was subsequently seen to fall down in a fatal swoon, this, together with the circumstantial evidence, might warrant the coroner's decision not to order an official inquiry. At the same time, we contend it is highly desirable that the exact cause of death should, where possible, be determined in every case. Anything short of this obviously allows of mistakes, and possibly in some instances leads to a miscarriage of justice. The records of our judicial proceedings clearly show that what has *à priori* been thought satisfactory proof of natural death has been really consistent with criminal intent and deeds.

OPPOSITION TO THE POISONS BILL.

THE opposition to the provisions of the new Poisons Bill continues with unabated vigour. In an article devoted to the subject in one of the trade journals, it is pointed out that the powers assigned to the Pharmaceutical Society are amply sufficient if only they were exercised with discretion. The omission in the Bill to define the term "poison" has been severely criticised, although it must be confessed that the difficulties in the way of a satisfactory definition are very great. Almost any substance capable of being absorbed into the circulation or of mechanically irritating the mucous membrane to a sufficient extent might cause death, the quantity necessary to induce a fatal result being one of degree only. A case is referred to of a gentleman who was poisoned by eating jugged hare in an advanced stage of decomposition. It is supposed that a fragment of bone caused an abrasion of the mucous membrane of the mouth or throat, and that this sufficed for the absorption of septic material. In another instance a young lady succeeded in destroying herself by swallowing a pound and a quarter of common table salt. Under the proposed Act it is probable that vendors of patent medicines containing active ingredients will incur a certain amount of responsibility, although the clauses dealing with the subject are so vaguely worded that it is difficult to foretell what will be the practical result of their operation. It is probable that the Bill, if not thrown out altogether, will be considerably modified in Committee.

PREVENTABLE DISEASES IN TOTTENHAM.

THE Tottenham Sanitary Association, which for many years past has done good work in stimulating sanitary work in its district, now publishes its eleventh report—namely, that for 1884. In a population of some 70,000, the death-rate was 16·45 per 1000. Typhoid fever and diphtheria were both excessive in their fatality, the last disease being three times more fatal than it was during the same period in London. As a result of this occurrence, special efforts are being made by the sanitary inspector to elicit information as to the state of the drains, their disconnexion and ventilation, whenever fatal zymotic disease occurs. This is good in its way; but it would be far better if, in addition to such action after the occurrence of the very result which should be avoided, the authority were to organise such a system of house-to-house inspection as would lead to the adoption of measures which would prevent the occurrence of diseases due to faulty drain connexions.

PERFORATING ULCER OF THE HAND.

THOUGH perforating ulcers occurring in the course of tabes dorsalis have their usual seat in the foot, there seems no reason why the hand should not be similarly affected. M. Terrillon showed a case of perforating ulcer of the palm of the hand at a recent meeting of the Société de Chirurgie. The ulcer was situate at the junction of the ring finger with the palm. The patient was a porter, and the subject of tabes dorsalis. M. Charcot did not hesitate to regard the ulcer as of dystrophic origin; pains and tinglings were experienced by the patient along the course of the ulnar nerve. A zone of anæsthesia was detected all round the ulcer. M. Nicaise inclined to the opinion that the ulcer was merely a corn which had become fissured, for the epidermis and cutis were thickened, whereas in perforating ulcers the cutis is thinned and even perforated.

ANTHRAX IN BERMONDSEY.

FROM time to time during the past few years cases of fatal anthrax have been reported at Guy's Hospital, arising in connexion with the Bermondsey tanneries. The most recent case occurred last week. The subject was a labourer, aged thirty-eight, employed in handling hides at a wharfinger's. Less than four days before his death he complained of feeling sick, and noticed a small pimple on the side of the neck; and the next day he presented himself at the hospital with well-marked symptoms of malignant pustule. At the inquest Mr. Langham, the coroner, drew public attention to the great importance of persons infected with the poison making early application for hospital treatment. The verdict of the jury, "Natural death from blood-poisoning," seems to us to have been scarcely sufficient; for it cannot be too widely known that the disease contracted from these infected hides is a definite and specific affection, and that every precaution should be taken to protect workmen against contamination.

EXPERIMENTS ON SOLDIERS' RATIONS.

EXPERIMENTS are being made in Munich, Mayence, Munster, and elsewhere, with companies specially formed of the strong men of different regiments. The men selected are obliged to submit for a fortnight to a strict campaigning diet, and during this period have to go through field exercises and route-marching for six hours daily in full marching order. Before and after every march out each man is carefully weighed. He receives daily a regulated quantity of a minutely described dietary—e.g., in Mayence, biscuit, coffee, pea-sausages (*Erbswurst*); in Munster, rye bread, brandy, and *Erbswurst*; the Munich *menu* has so far remained a secret. The men are constantly and closely watched, so that it is impossible for them to obtain any other food or drink than that laid down. The object of these experiments is to determine how long men will remain fit for work on such diet, and also to institute a comparison between the different diets tested.

ANTISEPTICS AND ERYSIPELAS.

FROM a statistical study of the surgical cases which have been under his care during the past five years, M. Polaillon has come to the conclusion that Listerism and carbolic dressings generally do not diminish the liability to the occurrence of erysipelas, though they lessen the virulence of the disease. In his experience women are more frequently affected than men, but the latter occupy the more salubrious ward. Sometimes the erysipelas occurred in isolated cases. Erysipelas was more frequent during the cold and wet months. Carbolised dressings, he avers, certainly attenuate the virulence of erysipelas. He has seen epidemics spread from patient to patient rapidly, yet making but few victims, and those only whose constitutions were enfeebled by long-lasting disease.

BALNEOLOGICAL CONGRESS.

THE seventh annual Congress of the Balneological Section of the German Therapeutical Society was held on March 14th and 15th at Berlin, under the Presidency of Professor Liebreich. Dr. Schott of Nauheim spoke regarding the importance of cutaneous resorption in connexion with the effects of baths. Dr. Grödel raised the question whether special balneo-therapeutical methods could be defined for various forms of spinal affections, but the discussion which ensued bore unfavourably on the possibility of such a treatment being perfected. Professor Eulenberg of Berlin spoke on the subject of electric baths, and the mode of their application to therapeutical purposes.

THE LONDON UNIVERSITY AND MEDICAL DEGREES.

WE understand that the Senate of the University of London have consented to receive, on the 29th inst., at 4.45 P.M., a deputation from the Metropolitan Counties Branch of the British Medical Association in reference to the question of granting medical degrees to London medical students.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council is summoned to meet on Tuesday, May 12th. The Executive Committee will meet on the preceding day, to arrange the order of business, &c.

THE DEATH OF LORD CAIRNS.

WE have authority for saying, contrary to the statement of some newspapers, that Sir William Gull never saw Lord Cairns medically, and was never requested to see him.

THE BICHLORIDE DOUCHE IN OBSTETRICS.

THE *New York Medical Record* reports that Dr. Hulbert, of St. Louis, stated, at a meeting of the St. Louis Medical Society, that he had salivated five patients with a bichloride solution (1 in 3000) given as a vaginal douche twice a day. No particulars are given, but it is evident that this agent, though a very effective antiseptic, will have to be used very carefully.

DR. J. F. STEVENSON, J.P., has just resigned the post of physician to the Birkenhead Borough Hospital. He was appointed as honorary surgeon to the institution in 1848, and having filled that office for a period of fifteen years, was appointed to the office which he has just resigned. Dr. Stevenson will continue his connexion with the charity as consulting physician. The committee have formally recorded their high sense of the valuable and efficient services rendered by Dr. Stevenson for this period of upwards of thirty-six years. Dr. Stevenson is to be congratulated, as it is not given to many members of even the medical profession to complete so long a term of gratuitous daily work.

SOME very exaggerated reports having been circulated concerning the prevalence of small-pox at Southend, it is well to mention that the case which is supposed to have been the first was not small-pox at all, but pleurisy; also that the sexton who was employed at the funeral, and who really died of small-pox shortly afterwards, caught the disease from his son, who was found to be suffering from it on his arrival from near London, and who has now recovered. We believe that, owing to the isolated position of the house and the care exercised by the medical officer of health, no other cases have occurred.

A CONTROVERSY on the subject of undue pressure in the public schools of America has been proceeding for some time, and from the *New York Daily Tribune* of the 24th ult. it now appears that the advocates of reform are steadily gaining ground, it being expected that the much-needed revision of the course of study and method of examinations in American schools will be substantially accomplished before the beginning of a new school year.

AN outbreak of English cholera, causing considerable alarm, is reported from Mountain Ash, where many people are affected in one part of the district called Caegarw, and one man has succumbed to the malady.

AT the Teachers' Conference at Norwich on the 8th inst., Mrs. Burgwin (Southwark) read a paper on over-pressure in schools, which she described as work against time to secure payment by results—a system injurious to teachers and torture to children, who were made disgusted with learning. She advocated the abolition of all grants under certain conditions, considering that education should not be hurried. A resolution was adopted to petition Parliament to appoint a Royal Commission to inquire into the existence, causes, and extent of over-pressure, it being felt that a departmental inquiry would not be satisfactory.

AT Jativa, in the province of Valencia, seventy persons have been attacked during the past fortnight by a disease resembling cholera. About half the cases ended fatally, and although several physicians have hesitated to pronounce the epidemic to be cholera, others who were sent to inquire into the outbreak affirm that it is that disease, and precautions have been taken to prevent its spread. The patients and their families have been put under canvas, and the houses where deaths have occurred have been disinfected.

MR. M. A. ADAMS, F.R.C.S., has devised a card containing the leading facts of importance in the record and investigation of contagious diseases. It embodies a neatly drawn-up chart to indicate the presumed normal periods of latency, premonitory fever, duration of pyrexia, and of the infectiveness of such diseases; and, being of convenient size, it should prove of some service. It is issued by Messrs. Churchill.

THE Paris correspondent of the *Record* says:—"A remarkable instance of confraternity has just occurred at Carcassone at the funeral of an eminent doctor, a Roman Catholic, who behaved most nobly during the last cholera epidemic. Three discourses were pronounced at the cemetery, one by the prefect of the Department, one by the president of the Doctors' Association, and one by the [Protestant] pasteur of the place, the Rev. Ad. Monod."

MR. ARNOLD TAYLOR, of the Local Government Board, has been holding an inquiry in the Ramsgate Town Hall concerning the loan of £20,000 required for the completion of the drainage and for the construction of new outfall works. Various difficulties and objections having been overcome, the opposition to the proposed scheme was nominal, and Mr. Taylor signified his intention of reporting favourably on the plan.

THE fourteenth Congress of the German Surgical Society met at Berlin on the 8th inst., under the presidency of Professor Langenbeck, who announced, to the manifest approval of the members, that the Committee had been pleased to nominate as honorary members Sir James Paget and Sir Joseph Lister.

WE are asked to state that applications for the appointment of Assistant Physician at Guy's Hospital, rendered vacant by the promotion of Dr. Frederick Taylor to the Physicianship, should be sent in on or before Thursday, the 30th inst.

WE learn that, at the unanimous request of the medical staff of the Paddington-green Children's Hospital, the post of senior physician will be filled by the appointment of Dr. Lauder Brunton.

THE eighth edition of Erichsen's Surgery is being translated into Spanish, and is appearing in monthly parts.

DR. ANGEL MONEY has been appointed Assistant Physician to the Hospital for Sick Children, Great Ormond-street, in the place of Dr. Barlow, promoted to the post of Physician to the institution.

IN a letter to the Lord Chancellor, dated April 6th, the Earl of Shaftesbury has expressed his decision to resign his seat on the Board of Commissioners in Lunacy.

THE

DRAMATIS PERSONÆ OF THE TERCENTENARY FESTIVAL OF THE UNIVERSITY OF EDINBURGH.

WE have good news for the alumni and graduates of the Edinburgh University. The event of the Tercentenary was one not likely to be forgotten. In itself it was one of the most remarkable gatherings of the men of light and leading in history. It produced, too, the "Story of the University," by the lamented and accomplished principal, Sir Alexander Grant, which is in itself guarantee that it will not be allowed to be forgotten. But as if this were not enough, a most exquisite volume of "Portraits of the High Officers and Professors of the University of Edinburgh at its Tercentenary Festival" has been published at the University Press by Messrs. T. and A. Constable. The volume before us, which is so charming as to disarm all criticism, is in a quarto form; but we gather that there are a certain number of folio copies to be had by those still more luxurious in their literary tastes. For ourselves, we are well content with and very grateful for the quarto form, which makes one of the pleasantest and most valuable additions to a library which we have seen for many days, and which cannot be too much praised either as regards the work of the printer, the compiler, or the artist. The artist is Mr. William Hole, A.R.S.A., who had already given some artistic intimations of the vivid impression made on his mind by the chief actors of the Tercentenary. In the forty or fifty portraits now presented to the public, the art of etching appears to the greatest advantage, and will hand down to a remote time a representation of the present professors. Even those learned professors whose physical qualities do not facilitate the etcher's art come out in style so natural and life-like as to be most interesting. And in the case of a few of the portraits, the result is most effective, as in that of Sir Stafford Northcote, of the lamented Principal, of Professor Blackie and his successor, of Professor Masson (in his slippers, sitting cosily by his fireside, and, low be it spoken, in the obvious enjoyment of his meerschaum), of Professor Turner, of Professor Fraser, of Professor Douglas Maclagan, of "John Chiene," of Professor Grainger Stewart, of Professor Rutherford, and of Professor Greenfield. Perhaps the most striking piece of art in the book is the portait of Professor Giekie, sitting on a boulder, a hammer in one hand and a geological specimen in the other style. The interest of the volume is greatly, if pathetically, enhanced by a frontispiece entitled "*Umbræ Quædam*," and giving the heads of professors and others recently dead who have shed lustre on the university, and whose fame still gives a strange fascination to the school—notably Sir William Hamilton, John Goodsir, David Brewster, James Syme, J. Y. Simpson, J. Hughes Bennett, R. Christison, J. H. Balfour, T. Carlyle, and others. Though the etchings and the general style of the book are the chief attractions of this happily conceived work, we should do great injustice to its promoters if we did not say a word in praise of the biographical sketches which are attached to each portrait. They are remarkably well done, occasionally perhaps betraying a little too much local complacency, but generally most readable and instructive. We cannot too strongly express our pleasure in possessing such a memento of so eventful an occasion. The only qualification of our satisfaction we have to make in our announcement of the book is that the number of copies is, we presume necessarily, limited. The impression for sale of the folio copies is 100, that of the quarto 750. *Beati possidentes!*

INTERNATIONAL CONGRESS OF HYDROLOGY AND CLIMATOLOGY.

THE first International Congress of Hydrology and Climatology will be held at Biarritz in October, 1886. Amongst the principal questions which will be brought before the members of the Congress are the following:—The Influence of the Phenomena of the Air on Mineral Waters, the Electrical Phenomena which manifest themselves in the presence of Mineral Waters, the Combinations which form Sulphur in the Waters termed Sulphur Waters, the Differences of Action between Fresh and Salt Water in Hydrotherapy, the Hygienic and Dietetic Rules to be observed whilst undergoing a course of Thermal Treatment, the daily Variations of Temperature in Sanitary Stations, General Characters of the Geological Constitution of the Pyrenees, the Hygienic Conditions which ought to prevail at Summer and Winter Health Resorts, the Influence of Sea Air upon Scrofulous Affections, the Influence of Winds, Quarantine by Land and Sea, &c. The Congress will last for eight days, and excursions to various places of interest in the neighbourhood will take place. The honorary president is the Minister of Commerce, and the acting president will be Dr. Durand-Fardel, the post of general secretary being filled by Dr. F. Garrigon.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Worcester Urban District.—In submitting his eleventh annual report to the Town Council of Worcester, Dr. Strange gives marked attention to cleansing of ashpits and cesspits, to the care of sewers and house-drains, and to the supply of drinking water to the inhabitants; and he does so with special reference to a somewhat heavy visitation of enteric fever from which the city has suffered. In the first place, Worcester still exhibits some of the old huge ashpits and cesspits, receptacles which were contrived in days when sanitary authorities were all but unknown, and when scavenging was a thing to be carried out as seldom as possible. Now, however, we know that these accumulations are hurtful in the extreme, and it should be a first object of the authority to get rid of such nuisances, especially in view of the risk they are to health. Much is, fortunately, being done in this direction, and it is to be hoped that there will be no need to recur to them in future reports, except as barbarisms of the past. As to the sewers, it is stated that complaints are made with respect to the emanations from the ventilators; but we can hardly agree with Dr. Strange that, inasmuch as these ventilators are only discharging their proper function, it is unwise to complain of them. Sewer ventilators should not stink. If they do, they are either not sufficiently numerous, or the sewers do not properly cleanse themselves, or else offensive house-drains are connected with them and foul them. If the sewers and house-drains are properly constructed so as to contain no stagnant contents, and if the ventilators are so numerous that a large number of them act as fresh-air inlets to dilute the sewer air before it escapes, then nuisance should not arise. But we fear that faulty conditions as to this exist in Worcester; for Dr. Strange talks of sewer air being forced back into dwellings unless it can escape into the streets. Such a forcing back should be impossible if there were an absolute break between the interior of the houses and the interior of the drains. In many hundred cases this break has now been effected in Worcester, and it is to be hoped that it will soon be universal. The detailed account given as to the water-supply to the city, now derived from the Severn, raises some very important considerations. As matters now stand, the Severn is liable to pollution by sewage and other organic matter after a heavy rainfall. Thus, the sewage of Kidderminster, during the great enteric fever epidemic there, got into the Severn fourteen miles above the Worcester intake, and the question now being dealt with is whether Worcester is to endeavour to remedy its river supply and improve its method of filtration, or to resort to an artesian well. In seeking advice, the opinion of the borough analyst has been sought, especially as to whether filtration would secure the inhabitants against "this great rce of danger" (i.e., "pollution by the germs of disease"), d he has answered, "If efficiently carried out, I believe it es." What this belief is based on we do not know, but e are quite certain that this view should not be acted on s regards a town water-supply. No such filtration as can e carried out by Worcester is likely to have the effect they wish to attain; and if the river is to remain subject to any such risks as hitherto, we should counsel its abandonment as a source of water-supply. The annual death-rate in Worcester for 1884 was 20·9 per 1000. Thirty-two cases, chiefly of enteric fever, were admitted into the Brabourne Hospital.

Lewes Urban District.—Lewes has for some years past had a satisfactory death-rate. Last year it reached 15·9 per 1000, somewhat in excess of the two previous years. Consumption is a somewhat fertile source of death, and we fear that the situation of the town at the foot of a chalk range in a river valley is a main cause in producing this result. The isolation hospital continues usefully to fulfil its purpose. The numbers admitted are not large, but the admissions prevent the extension of infectious disease, and, as Mr. Braden says, it would be impossible to say what mischief the thirty cases admitted since its construction would have brought about had they not been isolated.

Surbiton Urban District.—This suburban district enjoys a small death-rate. It was 10·8 per 1000 in 1883 and 11·9 in 1884, the rate for England and Wales during the latter year being 19·6. The zymotic rate is also low—namely, 1·4 per 1000. Infantile diarrhœa, too, which may be regarded as affording a valuable criterion of the healthiness of a place, only causes about 2 or 3 deaths per annum; in short, as a zymotic affection it is practically absent. Well water is, however, still resorted to, analysis almost invariably being such as to call for its abandonment. The ventilation of the sewers is engaging the attention of the authority, and a number of high shafts are being erected. There is as yet no hospital for infectious diseases. The neighbouring authority of the Kingston rural district have set an example as to this, and Dr. Coleman suggests inquiry as to whether Surbiton may share in its advantages.

Torquay Urban District.—The sanitary inspector for this district has issued a report showing the progress which has been made during the past year in the various matters coming within his cognisance, and it is certainly a record ery substantial advance. The detailed account of current rk relating to such matters as the ventilation of drains d soil-pipes, drain disconnexions, closure of wells, dis- fection of rooms, &c., relates to 4639 improvements. In ldition to this as many as 545 new houses have been over- oked during the course of their erection. The change hroughout the town from old, unventilated, choked, clay- ointed, untrapped drains to efficient, self-cleansing, and well ventilated conduits is in itself immense, and added to this work a large amount of incidental improvement has been effected in allied matters. Torquay aims at securing the reputation of being a real health resort, and such work as Mr. MacMahon gives an account of is eminently calculated to attain that end.

Belfast.—During the four weeks ending Feb. 21st the total births registered were 493, and the deaths 472, which latter included 216 deaths from lung affections. The average death-rate was, from all causes, 28 per 1000, from zymotic diseases 2·6, and from lung diseases 12·6. The general death-rate was a little higher than in January, though the rate from lung affections was 2 per 1000 less. Scarlatina still lingers amongst the population, but it is gratifying to learn hat both typhus and enteric fevers have almost dis- ppeared.

Cork.—During the four weeks ending the 21st ult. the births numbered 152, or a rate of 24·66; and the deaths 204, including 41 which took place in the workhouse. Excluding the latter, the mortality was equal to 33·09 per 1000. Compared with the corresponding return of last year, the death-rate has increased, and the birth-rate decreased.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5450 births and 3937 deaths were registered during the week ending the 4th inst. The births were 362 below, while the deaths exceeded by 310 the average weekly numbers during 1884. The annual death-rate in these towns, which had been equal to 23·5 and 23·2 per 1000 in the preceding two weeks, further declined last week to 23·1. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 21·9 per 1000, against 24·7, the mean rate in the corresponding periods of the nine years 1876-84. The lowest death-rates in these towns last week were 15·7 in Leicester, 17·8 in Bradford, 19·1 in Brighton, and 19·8 in Wolverhampton. The rates in the other towns ranged upwards to 32·6 in Norwich, 33·7 in Newcastle-upon-Tyne, 34·3 in Preston, 34·7 in Oldham, and 40·4 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 466, against numbers steadily increasing from 377 to 451 in the preceding five weeks; they included 173 from measles, 130 from whooping-cough, 45 from "fever" (principally enteric), 33 from scarlet fever, 32 from small-pox, 27 from diphtheria, and 26 from diarrhœa. No death was referred to any of these diseases in Derby last week, whereas they caused the highest death-rates in Norwich, Newcastle-upon-Tyne, Cardiff, and Sunderland. The highest death-rates from measles occurred in Bristol, Newcastle-upon-Tyne, Cardiff, and Sunderland; from whooping-cough in Oldham, Bristol, and Preston; from scarlet fever in Preston and Newcastle-upon-Tyne; and "fever" in Plymouth and Norwich. Of the 27 deaths from diphtheria in the twenty-eight towns 16 occurred in London and 2 in Norwich. Small-pox caused 54 deaths in London and its outer ring of suburban districts, 2 in Manchester, 1 in Birmingham, and 1 in Leeds. The number of small-pox patients in the metropolitan asylum hospitals, which had been 830 and 865 on the preceding two Saturdays, further rose to 879 at the end of last week; 141 cases were admitted during the week, against numbers increasing from 94 to 179 in the previous four weeks. The Highgate Small-pox Hospital contained 90 patients on Saturday last, 25 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 487 and 448 in the preceding two weeks, rose again to 478 last week, but were 65 below the corrected weekly average. The causes of 100, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Bolton, Wolverhampton, and Plymouth. The largest proportions of uncertified deaths were registered in Oldham, Preston, Sheffield, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 24·2 and 23·3 per 1000 in the preceding two weeks, rose last week to 25·0, and exceeded the rate last week in the twenty-eight large English towns by 1·9. The rates in the Scotch towns ranged from 15·2 in Leith and 17·0 in Edinburgh and Aberdeen, to 30·8 in Paisley and 31·5 in Glasgow. The 600 deaths in the eight towns included 34 from whooping-cough, 23 from measles, 11 from scarlet fever, 6 from "fever" (typhus, enteric, or simple), 5 from diarrhœa, and not one from small-pox; in all, 84 deaths resulted from these principal zymotic diseases, against 85 and 73 in the preceding two weeks. These 84 deaths were equal to an annual rate of 3·4 per 1000, which was 0·7 above the mean rate from the same diseases in the twenty-eight English towns. The deaths from whooping-cough, which had been 35 and 32 in the previous two weeks, were 34 last week, of which 22 occurred in Glasgow, 4 in Edinburgh, and 4 in Dundee. The 23 fatal cases of measles showed an increase of 8 upon the number in the previous week, and were all returned in Glasgow. The 11 deaths from scarlet fever also showed an increase upon the number in the previous week, and included 5 in Paisley, 3 in Glasgow, and 2 in Edinburgh. The 6 deaths referred to "fever" corresponded with the number in the previous week, and included 3 in Edinburgh and 2 in Greenock. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 124 and 122 in the previous two weeks, rose to 130 last week, and exceeded the number in the corresponding week of last year by 22. The causes of 103, or 17 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 39·5, 34·6, and 40·4 per 1000 in the preceding three weeks, declined again to 33·6 in the week ending the 4th inst. During the thirteen weeks ending last Saturday the death-rate in the city averaged no less than 34·0 per 1000; whereas in the same period the rate did not exceed 21·6 in London and 20·0 in Edinburgh. The 227 deaths in Dublin last week showed a decline of 46 from the exceptionally high number in the previous week, and included 24 which were referred to the principal zymotic diseases, against 30 and 32 in the preceding two weeks. Of these 24 deaths, 13 resulted from measles, 5 from "fever," (typhus, enteric, or simple), 4 from diarrhœa, 2 from scarlet fever, and not one either from small-pox, diphtheria, or whooping-cough. The annual death-rate from these principal zymotic diseases was equal to 3·5 per 1000; in London and Edinburgh the rates from these diseases last week were equal to 2·6 and 2·1 respectively. The fatal cases of measles in Dublin, which had been 16 and 12 in the previous two weeks, were 13 last week. The deaths referred to scarlet fever and "fever" were respectively 5 and 1 below the numbers in the preceding week. Three inquest cases and 3 deaths from violence were registered within the city; and 86, or 38 per cent., of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable decline from the high numbers in the previous week. The causes of 26, or 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL SCHOOL.

THE fiftieth session of the Army Medical School was opened at Netley on the 2nd inst. Forty-five surgeons on probation for the British army and five for the Indian army have joined. In consequence of the urgent need for medical officers, these gentlemen will only remain for two months instead of four, their places being taken by a second batch, who will join early in June and be dismissed in the beginning of August. The introductory address was delivered by Professor Aitken, F.R.S., who gave a philosophical lecture dealing with the application of the Darwinian hypothesis and the evolution of disease. The Director-General, Dr. Crawford, was present, and addressed some words of counsel to the surgeons on probation. Sir Joseph Fayrer, K.C.S.I., Surgeon-General Murray, Colonel Bell, and the officers of the school and hospital staffs were also present.

Several lady nurses from the Guards Hospital in London have left for Suez for duty with the Guards' field hospital at that place.

It having been decided to separate the duties of the medical administration of the troops stationed in the Home and Woolwich districts, which have hitherto been vested in one officer, Surgeon-General Sir James Hanbury, who was principal medical officer in Egypt during the campaign of 1882, takes over the medical charge of the Home district, and Brigade Surgeon T. Rudd that of the Woolwich district.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon Alfred Hubert Kelly, B.A., M.D., has been allowed to withdraw from Her Majesty's Naval Service, with a gratuity.

The following appointments have been made:—Staff Surgeon Edward E. Mahon, to the *Bacchante;* Staff Surgeon Herbert M. Ellis, to the *Sapphire;* Staff Surgeon Robert W. Williams, to the *Pegasus;* Surgeon H. G. Jacob, to the *Racer;* Surgeon J. M. Rogers, to the *Agincourt;* J. W. Grene, to be Surgeon and Agent at Crookhaven; Fleet Surgeon James Flanagan, to the *Cambridge;* Fleet Surgeon Garland W. L. Harrison, to the *Northumberland;* Surgeon Herbert W. G. Doyne, to the *Bacchante;* Surgeon James C. F. Whicher, to the *Agincourt;* Surgeon Henry G. T. Strickland, to the *Victor Emanuel;* and Surgeon J. D. Henwood, to Plymouth Hospital.

A trained naval sick-berth staff is being established, and boys, who will be medically examined as to fitness for the service, will be selected from Greenwich Hospital School, the mercantile marine, and other sources. After completing a year's service in a training ship they will be sent to Haslar Hospital, where they will receive instruction in elementary anatomy, bandaging, in dressing wounds, and such other exercises as will enable them to render first aid to the wounded afloat and ashore. After performing these preliminaries the candidates will undergo an examination, and if found qualified they will be rated as sick-berth attendants with Admiralty approval. A notice has also been published that, pending the introduction of the new scheme, a few young men, whose age is between eighteen and twenty years, will be trained as nurses. They will have, if fit for the duties, all the advantages of the new system.

"STRANGULATED OMENTAL HERNIA."

To the Editor of THE LANCET.

SIR,—Some time ago Mr. Rushton Parker published a short work on "Abdominal Hernia," in which he questioned the usual doctrine that the strangulation of omentum only in a hernia will produce the same symptoms (though possibly less severe) as are produced by strangulation of the intestine, and he repeated his views in your columns on May 17th, 1884. He called attention to the fact that in my work on the "Principles and Practice of Surgery" I had supported the usual teaching, although I thought it right to call attention to the circumstance that the ligature of the omentum produces no such symptoms. Mr. Parker believes that the old doctrine is erroneous, and that the symptoms, in cases where strangulation is believed to have occurred in herniæ, which are really epiploceles—i.e., purely omentum—are due either to obstruction resulting from the dragging of the omentum on the colon, or to peritonitis, or to purely functional obstruction of intestine due to some other cause, and unconnected with the epiplocele except by simultaniety of occurrence;[1] whilst he believes that there is another class of cases in which the hernia is not really omental only; but that a piece of bowel has been in the sac, but has somehow got reduced either during the operation, or by the taxis just before the operation. I replied to Mr. Parker's criticisms in a letter which you published on August 4th, 1883, in which I hesitated to accept the second hypothesis (that of the reduction of previously strangulated bowel). As, however, a case has lately occurred in my own practice showing the reality of the fact, I hasten to put it on record in justice to Mr. Parker, as well as in consideration of the interest of the surgical question itself.

The heads of my case are briefly these:—An old man (aged seventy-three) was admitted into St. George's Hospital during the night of March 19th for umbilical hernia, with constipation and vomiting. I was accidentally absent, and a colleague was called in, who saw no reason to interfere by operation. Nor did I when I saw the man next day. He had had the rupture for two years. Latterly he had had a bad cough, and the tumour had become larger. On the previous day, after a severe fit of coughing, he suddenly experienced great pain at the umbilicus, and increased swelling. He began to vomit soon afterwards. The vomiting, however, at first was almost entirely of the contents of the stomach, and seemed to be excited by his cough. I must not burden your space with all the particulars of the case. Gentle attempts were made to reduce the hernia, but with no effect, on March 20th, and I believe no serious effort at taxis was made on any subsequent occasion. The man went on in much the same way for three days; but then the vomit became obviously more "fæcal"—i.e., it was no longer from the stomach only but from the small intestines, and his strength began also to fail, so that it was clear that if not relieved he would die. At the same time, his chest was so full of rhonchi, and his heart's action so feeble, that I was unwilling to give an anæsthetic. On March 23rd the parts over the sac were frozen and divided, and the sac found tightly constricted. The stricture being freely divided, attempts were made to reduce the hernia; and these not succeeding, the sac was opened, and nothing found in it but congested omentum, which was removed after tying its stalk with a double catgut ligature. The vomiting continued, and the patient died eighteen hours afterwards. On post-mortem examination the omentum was found adherent, not to the neck of the sac, which was quite free, but to the parietal peritoneum *inside* the belly. The portion in the sac could not, therefore, have exerted any traction on the colon, nor was there any serious displacement or any loading of that portion of the bowel. But about four inches from the ring was found a knuckle of small intestine, which had obviously been recently strangulated, and is thus described by our curator, Mr. Shield:—"It was about two inches in length, congested, and claret coloured, and was terminated above and below by the dark narrow furrow, both discoloured and contracting the bowel, which is commonly seen in intestine reduced in hernia, and s unmistakable in appearance." The fresh appearance of he constrictions and the still congested condition of the bowel appear to me conclusive proof that the reduction of he constricted intestine must have taken place during the peration, eighteen hours before death, and not in the ttempts at taxis three days before.

---

[1] Of this last view Mr. Parker gives an example in the accompanying letter.

The case proves beyond reasonable doubt that Mr. Parker s right in believing that some of these cases are not cases of ure epiplocele at all, and that I was wrong in thinking hat an experienced surgeon could not have reduced a small nuckle of bowel without being aware of the fact, or oticing an unoccupied portion of the sac from which the owel had been reduced. It does not, however, convince e of the truth of Mr. Parker's opinion, that strangulation f omentum only cannot produce the symptoms which I ave indicated, and I confess that I still hold the opinion ated in my book, in connexion with many other surgeons, ho also have met with cases inexplicable to their minds n any other way, difficult, as it may be, *to form a satisfactory theory* of the occurrence. At any rate, I thought it y duty to ask you for space to record this case.

I am, Sir, yours truly,
Great Cumberland-street, April 6th, 1885. T. HOLMES.

To the Editor of THE LANCET.

SIR,—Mr. Timothy Holmes has had the great kindness to t me see the copy of his letter, in which he makes very ndsome reference to me. Having myself found post-ortem evidence of previous intestinal replacement in fatal rangulated hernia that had been, or was capable of being, pposed to be mere epiplocele, I had the best grounds for lieving that a similar condition of things could occur ain. The combined circumstances that render this obsertion possible must be so rare that Mr. Holmes's independ nt confirmation lends to my contention a support without hich many would fail to be impressed by it. After all, owever, his case, like the one I referred to, merely shows how, a certain rare, but always possible, class of cases, to avoid e fallacy of attributing to strangulated *omentum* symoms really caused by strangulated intestine. I continue shaken in the firm conviction that strangulation of entum alone, *as* strangulation, can have no symptoms, eing that the tightest ligature never produces them. nong the various explanations that can be given of the doubted symptoms that are found in cases where omentum one exists, and is supposed to be strangulated, I mentioned e occurrence of intestinal obstruction of the "*functional*" nd in persons who happen to also have an omental, though rmless, hernia. It is not a very uncommon thing to eet with patients who suffer from constipation, vomiting, griping, or vague abdominal distress. Such cases are remedied by fasting, by rest and warmth, and by the narcotic assistance of opium, alcohol, or both. In my pamphlet on "Abdominal Hernia" I asked, "Why such symptoms should not now and then occur to persons already possessed of a hernia?" They are, in fact, perfectly well known in old large herniæ, especially umbilical; and although the hernia of intestine is often, if not generally, at fault, even if not strangulated, by being materially hampered through adhesions, &c., still such symptoms have often nothing whatever to do with the hernia. It must be so, for surely persons do not require a hernia in order to get "bowel complaint," whether it be diarrhœa, constipation, or mild obstruction. Such being the case, it is contrary to common sense and clinical experience to put down such symptoms at once, and in every case, to the supposed strangulation of a previously long harmless omental hernia. Such a case I, not long ago, witnessed. On Dec. 22nd, 1884, I saw, in consultation with Mr. H. O. Thomas, an old lady of nearly seventy who had long had an irreducible omental femoral hernia. For two or three days previously she had had constipation, vomiting, furred tongue, loss of appetite, griping, and general abdominal distress. The hernia, moreover, had increased in size, but whatever its contents, it was not resonant on percussion. Taxis was very gently attempted under an anæsthetic, as well as without, but the hernia could not be in the least altered in bulk or shape. The case we both admitted to be consistent with the existence of functional obstruction of intestine, independently of the hernia; yet, knowing how insidiously strangulation of intestine occurs, without much addition to the hernial bulk, I felt that operation would be the wiser course to make sure. But Mr. Thomas rather held to the view that the hernia was not in this case in fault. So after ample discussion I agreed to his proposal to trocar the centre of the hernia for exploratory purposes. The only issue was blood-stained serum, without odour at all, on which it was agreed that we had not reached intestine and that the patient could fairly be left to medical treatment. A little morphia was given under the skin and the mouth merely moistened with necessary liquid, the result being entire cessation of symptoms and speedy recovery. Cases like this show that the whole casuistry of the subject is rather more intricate than is often imagined, and prove more and more how well founded is the very reasonable rejection of the doctrine assigning symptoms to mere strangulation of only omentum. It has occurred to me while writing that some might think that a portion of intestine was possibly here reduced in the manipulations. This is not possible; we were keenly on the look out for any such fact, which would have been welcomed, and could not under the circumstances have eluded observation. No change whatever in the bulk of the hernia resulted until it was tapped. A similar case is recorded by Mr. Thomas at the end of his work on intestinal obstruction, but the above is the first that I have myself recognised. Pray excuse the length to which I have gone.

I am, Sir, yours truly,
Rodney-street, Liverpool, April 6th, 1885. RUSHTON PARKER.

"SMALL-POX AND VACCINATION."

To the Editor of THE LANCET.

SIR,—In your last week's notes in Parliament, at p. 643, it is not made clear that the seventy-eight persons engaged at the London small-pox hospitals, about 7 per cent. of the whole number employed, who had had small-pox had it before they were engaged at those *hospitals*. When Mr. G. Russell from his official position had to state that his department had no reason to *doubt that* "none of the nurses at any of the London small-pox hospitals who had been *duly vaccinated before entering on their duties* have ever caught small-pox" is substantially accurate, he goes on to say that this might have been more guardedly expressed in "Facts concerning Vaccination." The words now put in italics show how sufficiently the expression is guarded, and most members of the Local Government Board would probably admit this.

Of late it has been common to report cases of small-pox after vaccination, not only when the vaccination was performed after the reception of small-pox infection, but also where there is no evidence of any effect of revaccination having been produced. In times of great pressure persons have been engaged for duty at small-pox hospitals before their revaccination *was* known to be effective. Even a previous attack of small-pox is not a positive safeguard unless tested by a revaccination. All the evidence accumulated to the present time conclusively proves that vaccination has lost none of its protective power, and we are constantly reminded to our cost that small-pox has lost none of its virulence.

I am, Sir, your obedient servant,

April 4th, 1885. WILLIAM SQUIRE, M.D., F.R.C.P.

DONBAVAN v. MORRISON.

To the Editor of THE LANCET.

SIR,—The above case came on for trial before the judge of the county court, Croydon, on the 31st ult. After all the points on which we relied had been ably put forward I regret to state that the judge, without calling on the defendant's counsel for reply, gave judgment in his favour, giving costs also on the higher scale, alleging as the grounds for his decision that he held that a workhouse and workhouse infirmary were public institutions within the meaning of the 5th section of the Coroners' Witnesses Act, and that the officers of such institutions were not entitled to payment for making post-mortems and attending and giving evidence; thereupon our solicitor applied for leave to appeal, which the judge, after some hesitation, assented to.

This decision, if not upset on appeal, will seriously affect the interests of all workhouse medical officers, who in future will not be paid for such examinations and evidence, and it practically reverses the system that has been followed since the Act came into force, which has been to pay workhouse medical officers for such examinations and evidence.

The trial so far will cause a heavy drain on the very limited income of our Association, and without immediate pecuniary assistance it will be impossible for us to prosecute further proceedings. May I ask, therefore, my professional brethren who are able and willing to at once announce their intention of supporting us by forwarding subscriptions to me. I am, Sir, yours obediently,

JOSEPH ROGERS,
Chairman of Council, Poor-law Medical Officers' Association.

31, Montague-place, W.C., April 1st, 1885.

"ALLEGED DEATH FROM VACCINATION."

To the Editor of THE LANCET.

SIR,—After reading your article I feel it due to myself, being misunderstood, to say:—1. That I accept, and have for twenty years accepted, the proposition that vaccination modifies small-pox. 2. I do not consider "arm-to-arm vaccination an undesirable method of procedure," except in the case of tuberculous infants. 3. I was called urgently, for the first time, on the 14th ult., to the deceased infant, H. J. Downing Walker, because the child was "in a fit." The difficulty in breathing spoken of in Court by Mrs. Walker was on the 12th ult. Any observations made in Court as to the effect of point vaccination as compared with arm-to-arm vaccination were given only as the result of my own individual experience. Finally, in the certificate, which the superior wisdom of a coroner's jury was pleased to condemn, it was my intention to state, according to my light, the prominent medical facts preceding death, and that being so, the certificate, when written, was a "correct statement" of the opinion of

Your obedient servant,

Regent's-park, N.W., April 6th, 1885. C. C. WHITEFOORD.

AN EASY METHOD OF CURE FOR SALIVARY FISTULA.

To the Editor of THE LANCET.

SIR,—The following method does not appear to be mentioned in any of the usual text-books of surgery:—

J. K——, a fish salesman, came to me about the New Year with a fistula of the parotid duct resulting from a former knife wound. The flow of saliva was continuous, but was much aggravated at meals, and when opening oysters in the course of his business. Applications of nitrate of silver, pure nitric acid and a hot wire were tried without success, as all communication with the mouth seemed shut off. On Jan. 20th two needles threaded on one fairly strong piece of silk were successively passed through the fistula into the mouth on a rather lower level than the external fistulous orifice, piercing the buccal mucous membrane about a quarter of an inch apart. The needles were then removed, and the threads firmly tied and cut off short, thus leaving a ligature enclosing part of the internal wall of the duct, a portion of mucous membrane, and the intervening structures, but in no way preventing the healing of the external wound, as would be done by the seton usually recommended. The edges of the fistula were touched with pure nitric acid on Jan. 22nd, and some swelling of the side of the face ensued. On Jan. 25th a scab had formed outside, and nearly all the saliva found its way into the mouth. This scab came off a few days later, leaving the skin soundly healed, and the ligature inside cut its way through the mucous membrane on Feb. 11th, since which time the man has experienced nothing differing from the normal condition.

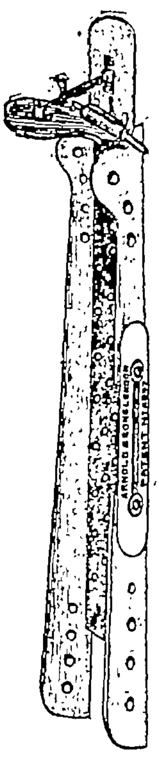
I am, Sir, yours faithfully,

Rochdale, April 6th, 1885. ALFRED HODGSON, M.B. Aber.

IMPROVED FRACTURE BOX.

To the Editor of THE LANCET.

SIR,—I wish to bring under your notice a new invention, which I presume will be of great advantage to surgeons in the treatment of fractures of the leg. It is an improved fracture box, suitable for any fracture of the leg, simple or compound, or disease of the ankle-joint requiring rest in position. It consists of three pieces: bottom and two sides. The bottom is pierced with drainage holes, and has a hinged foot-plate attached. This foot-plate is further connected to the foot end of the bottom splint by a regulating screw. This screw is a "fine thread" screwed socket rotating on a screwed pin. This screw regulates the angle at which the foot-plate is required to be kept. One of the side splints is plain; the other is in two parts, kept together by a brass slide having a longitudinal slot of the diameter of the thumb-screws, on which it runs, and which serve to retain it in position. This is the "interrupted" splint of the fracture box. It can be made a plain splint if required, or can be fixed at any divergence by the thumb-screws. One of these interrupted splints is only required, as both side splints are reversible, and will fit either side of the apparatus. The usual straps and buckles tie it together. The accompanying woodcut will assist in giving a clear idea of the nature and construction of the apparatus.



I remain, Sir, yours sincerely,

JAMES J. FOLEY,
Medical Officer, Midleton Hosp.

Riversdale, Midleton, co. Cork,
April, 1885.

NEW WORKHOUSE INFIRMARY AT WEST BRO-WICH.—The *Building News* gives a lithograph of the Ne Infirmary, West Bromwich. Accommodation is provid for 224 patients. The arrangement of the wards is on th pavilion system. The contagious and infectious are separated from the buildings, and so arranged that ea ward may be isolated. None of the buildings exceed t storeys. The staircases are of stone, and ...... T hydrants have been placed in convenient positions. T cost of the infirmary has been about £12,500.

WITH THE TROOPS IN THE SOUDAN.

(From our Special Correspondent.)

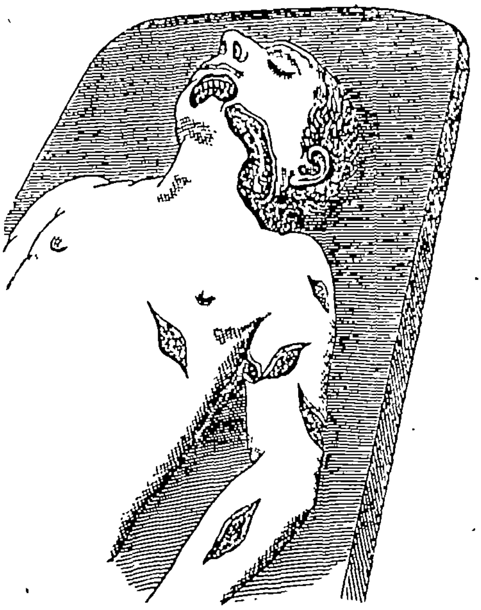
Base Hospital, Camp near Suakim, March 23rd, 1885.

Footsore, *dust-begrimed, and desperately tired, I sit* down to write you a few lines from this entrenched spot, as I feel assured any information from the front, however brief, will be welcome from this newly selected battle-field of the African Soudan. Scarcely had I arrived in this port ere *private news reached me of a projected advance of our* troops in the direction of Tamai, *en route* for Berber. I at once proceeded on foot under a blazing sun to the head-quarters of our camp, situate about a mile from the Arab town, and sought an interview with General Graham, now in command of the troops out here. On inspecting my papers, however (your certificate of appointment as "special" I refer to), he remarked *that* my credentials were not exactly in order, and explained to me that a properly attested registration certificate should have been obtained from the proper authorities at the Horse Guards, in order to place me on the same footing as other specials accompanying the troops in the field. I explained how hurried my departure had been from England, and after a few minutes' conversation the difficulty seemed *to* be bridged over, and a very pleasant interview terminated in the Chief of the Staff pointing out the principal *medical* officer's tent, and referring me to that gentleman for any future instructions for my guidance on the subject. Surgeon-General Barnett at once received me in a most cordial manner, expressed his pleasure at meeting a *repre*sentative of The Lancet, and assured me that no ob*stacle whatever would* be placed in my way, but every facility possible afforded for my obtaining any medical *or* surgical records of such cases as I thought fit to notice, and were likely *to interest* the profession at large, at the same time handing me a paper (a general order) for my perusal, whereby I was enabled at a glance to ascertain that a very careful disposal of the medical staff had already been made in view of the troops moving westward to confront and give battle to the enemy in the plain.

On Thursday *morning* last, March 19th, I was aroused at A.M. Hurriedly dressing, partaking of biscuit and a good cup of strong coffee, and then filling my small handbag with tourniquet, some artery forceps, surgical needles, silk, and such other *necessaries likely* to be *useful*, as well as comforting in case of accident or delay on the road, I quitted the easy quarters on board the steamship *Arab*, and proceeded on shore in company with a "special" bent on a representative errand as myself. On arriving at headquarters, we found the column *had left the camp about* an hour before our arrival, and not being able to secure a horse for myself, I *had to part* company with my companion and follow General Graham's force to Asheen on foot and alone—a by no means happy prospect, in view of a *some seven or* eight miles' dusty walk over a sandy desert under the scorching rays of a tropical *sun*, and in the *presence of a subtle*, active, and relentless foe. By the time the sun had risen, a light, cool, northerly breeze had sprung up, so that my solitary tramp turned out not quite so unpleasant a one as I expected it would have been. Doing my level best, as they say—some five miles an hour,—I came up with the rearmost of the camel train, in charge of native Indian drivers, and in an hour afterwards I had forged so far ahead that I could easily discern the entire distribution of the force in front, and at two hours from the time of leaving the ship was up with and coming on at a canter with the Brigade of Guards, and felt not much the worse for my long walk. Soon afterwards a halt in front, and an order from the General for *the camels and mules to immediately* come into square, suggested the probability of a "find," either for *refreshment* or foe. "Breakfast, I guess," says a sturdy mule-driver close to me, the wish *on his part* being father to the thought, as our stomachs were by this time empty *enough*. Not long, *however*, had we to wait for a decision on this point. An extended line of *white-greyish* smoke making its appearance over the helmets of the men standing in *front of* us, *and the sharp* rattle of musketry heard on our left front face told no uncertain tale, but *proclaimed the fact* that the enemy were there—more than that, not at bay, but, as their usual custom *and valour* is, were charging right up to our very front. Cavalry, with their gaily decorated *lances*, were seen dashing along in one direction, whilst our Guards, the 49th, 53rd, and 70th, were doing their very best pegging away in another. The din of battle proceeded, whilst dust and smoke soon obscured from view nearly everything going on around us. After quitting the camel convoy I had marched on with the Guards, and then joined the *hospital* and bearer company, hoping to see what wounded were brought in from our front face of the square; but in the hurry and *scurry, the confusion and rapidity of movements* going on around me, I for a time lost touch of the medical department, and, by getting out of the way of a score or so *of refractory camels, suddenly discovered myself outside* of the square that had fortunately, and yet quickly, been formed at the base of a small hill to resist the onslaught of a most brave, active, and determined enemy. *For some* seconds I was at a loss to know what to do. There I stood alone, unattached, and withal perfectly unarmed. I felt *for at least once in my life that I had outstepped the bounds* of discretion, and had really no business where I was, and further than that, if I remained much longer just at that particular *spot looking* at the action, and admiring the pluck as well as the dash of our own brave fellows in mounting the spur of the hillock, and carrying up planks and bags to form a *zereba*, the occasional thinning of the dust cloud and blowing away of the smoke giving me an opportunity now and then of getting a glimpse of what was going on in this tug of war, I myself would be as near as possible in a line betwixt two fires, and form an admirable *target* for either side which should choose to fire upon me. I was in a dilemma, it is true, having to determine upon one of two dangerous alternatives—either to dash back through the dust and smoke and try to regain the inside of the Guards' square, with the prospect of being mistaken and shot at as an enemy, or make for some safe distance in the rear. Acting on a natural instinct, impulse if you will, and which has stood my friend on many a trying occasion before, I decided for the latter, and at noon exactly started across the plain *for* Suakim, and the entrenched camp some seven miles away. Two young men, who had come out with the force in the morning, joined me a few minutes afterwards, and I at *once* felt relieved by their companionship in this retrograde movement on our parts; however, they, like myself, were amateurs, and had come out of camp—just as Easter Monday holiday folk do on Brighton Downs to see what was going on; and one of them had in his possession a large, ugly revolver, which he persisted in carrying in his hand at full cock. As I considered there might possibly be, from inexperience in its use on his part, more danger in this friend than in a foe, it was with no small degree of relief to my feelings that we three parted company, having reached a place of comparative safety about four miles away from the action that was then going on. By 2 P.M. I was inside the West Redoubt, the furthest post out held by the English in the plain, and learnt from the officer in charge, Lieut. the Hon. H. White of the Guards, the great danger I had run in going out, and especially in coming in unarmed over a wide plain that might then actually be in possession of the enemy, who give no quarter, but slaughter every man and beast they meet. *From* the crow's nest of this redoubt we watched the fight going on; saw that the brave British force had already secured the low hills which dominated the wells; but had formed a zereba as well as established heliographic communication between head-quarters and themselves. By three o'clock the fight was practically over. The gallant 70th were left to hold the zereba, and the remainder of the expeditionary force returned to camp to give the men a good meal, and get a little rest in their entrenched position after a most fatiguing march out, and the gallant exploits of the day.

Poor Lieutenant Dalliston, of the Guards, fell early in the day, shot dead, and very soon afterwards Surgeon Lane, also of the Guards, as gallant a fellow as ever breathed, and as *accomplished* a young surgeon as ever graced the pages of the Army List, sank to earth pierced by *a bullet* wound through his left lung. He was very carefully brought back to camp; *considerable* hæmorrhage meanwhile ensued, and all felt that his wound was desperately dangerous. The following morning he was dying, no possible hopes whatever being entertained that he *could live out the day*. He breathed his last about two o'clock in the afternoon. *Every* care and attention was paid him by his medical brethren, but all to no purpose. He passed away in the prime of life and pride of manhood, to give place for others to emulate him in quality and action, as well as to place another lasting testimony on the record of fame that there are men in the non-combatant as well as the combatant branch who are prepared to lay down even their lives, if needs be, in the execution of their duty for their Queen and their country. I had telegraphed to you early in the day of the serious character of his wounds, as well as that of some other officers; but from some misunderstanding on the part of the telegraphic company, all messages now being under a military censorship prior to being sent away, my report, containing ciphers to save expense, was stopped, and handed back to me in consequence.

Our list of casualties in this slight action, and the day day following, when a relieving column was despatched to the zereba, was heavy enough. Sergeant-Major Nicholls was stabbed to death, and some men of the 2nd Scots, 1st Coldstream, and 2nd Grenadier Guards fell mortally wounded by Remington bullets. Major Robertson, of the Bengal Cavalry, was stabbed by a spear very severely. Major Harvey, of the 5th Lancers, received a bad thrust through his left thigh, but is doing well. Most of the wounds were gunshot ones, the rebels not getting within thirty yards of our squares. The injuries inflicted by spear thrusts are simple clean flesh-cuts, the enemy's weapon having a razor-like edge. These wounds under ordinary antiseptic dressing do well, and generally heal by first intention. Their large double-edged sword, used with great force, held in the two hands, and generally aimed at the neck and head, produces most ghastly wounds, severing flesh, vessels, and bones in the course of its descent, and killing its victim outright. No man unhorsed in fight ever escapes the fury of these ruffians, nor lives to tell the tale of a hand-to-hand encounter with their active and brave but relentless, foes. (*Vide* sketch.)



Corpse of a private after falling into the hands of the enemy. One sword-wound in the neck, severing everything through the cervical vertebræ; the rest are spear-wounds on the chest and arm, six in number. (Sketched at Base Hospital, March 23rd, 1885.)

Saturday (21st) was a quiet day as far as the home force was concerned; but much firing was heard in the direction of the Hasheen zereba, although no reports had come in from them until Sunday, the 22nd.

On Sunday (22nd) a large force left the camp before daylight, taking a southerly direction towards Tamai, twelve miles distant. Five or six miles out, the camp, whilst the men were building a zereba, was surprised by a large number of the enemy, and a regular stampede among the camels and camp followers in consequence ensued. The details of this affair must sooner or later reach England, and some explanation will be required to account for the sad loss of life that has taken place amongst the troops and men employed. As I write this an order has reached the Base Hospital from headquarters for the medical staff to be in readiness to receive a large number of wounded from the field. A large and powerful escort has gone out to bring the wounded in. During the whole of this day (Monday, 23rd) Brigade-Surgeon Hinde, assisted by his energetic staff at the redoubt, have been working hard to have everything in readiness to receive them. About 100 are expected. In this camp Surgeon-Major Tanner can accommodate 70 in beds, 20 can be taken in the Auxiliary Hospital at Quarantine Island, whilst 55 could be removed on board the *Ganges*.

The hospital tents are both roomy and airy, being lined with double protective covering overhead, and are square, not bell-shaped, as wrongly described by some correspondent. The operating tent, under the superintendence of Surgeon-Major Tobin, is a picture of comfort, method, and order, and reflects much credit on the indefatigable officer in charge of it.

7 P.M.—Just dusk, and the wounded are being brought in. Poor fellows, I pity them indeed! Their faces, and those of the gallant band who have brought them, are so brown and covered with dust that they are scarcely recognisable; but never mind—comforts, in the shape of a nice bed, good warm soup, hot tea, or even brandy-and-water, await each one, as the necessity of his case demands it. The dressings, moreover, are so carefully adjusted, and the patients seem to have had such good attention in the field, that they will enjoy the comfort of a quiet night before their wounds are further inquired into.

LIVERPOOL.

(*From our own Correspondent.*)

MEDICAL FACULTY, UNIVERSITY COLLEGE.

THE vacancy caused by the resignation of Dr. Ewing Whittle, of the chair of Medical Jurisprudence and Public Hygiene, has been filled by the election of Mr. Frank T. Paul, surgeon to the Royal Southern Hospital, and surgical tutor in University College. Mr. Paul possesses eminent qualifications for the chair, having been a pupil of the late Dr. Alfred Swayne Taylor at Guy's Hospital, and having also held the appointment of pathologist to the Liverpool Royal Infirmary, where he was previously resident medical officer for nearly three years. He has personally made upwards of 1000 post-mortem examinations, and was for some time demonstrator of physiology. Altogether, the appointment is one on which the College may be congratulated.

THE LOCK HOSPITAL: COMPARATIVE RARITY OF SYPHILITIC IRITIS.

At a recent meeting of the Medical Institution, Dr. Bernard, surgeon to the Lock Hospital, read a paper on "The Treatment of Constitutional Syphilis," in which he remarked on the rarity of cases of syphilitic iritis seen in the hospital. The total number of patients treated averages over 600 annually, of whom the larger proportion are suffering from constitutional syphilis. Mr. Shears, senior assistant-surgeon to the Eye and Ear Infirmary, who took part in the subsequent discussion, observed that syphilitic iritis was very frequent among the out-patients of that institution. Subsequent inquiries showed that in a period of ten years (May, 1875, to March, 1885) there had been only seventeen cases observed in the Lock Hospital, and in the majority of these the eye is affected either on admission or very shortly afterwards. A very probable explanation is that the cases seen at the Eye and Ear Infirmary are those of patients who have neglected the primary disease, the influence of mercurial treatment in both preventing and curing syphilitic diseases of the eye in particular, being now undisputed.

STREET NOISES.

For some years past most of our leading thoroughfares have become insufferably noisy, there being an incessant roar of traffic from a very early hour in the morning until very late at night. The wood pavement does not appear to find much favour with the local authorities, who have only permitted a very limited use of it in the neighbourhood of the Northern Hospital, in Bold-street and part of Church-street, thoroughfares devoted to fashion. The asphalte pavement deadens the sound somewhat, though it has the disadvantage of being very dusty. Medical practitioners, who are obliged to live in or near leading thoroughfares, suffer much from this annoyance, as also from much noise which might be avoided, such as street music and singing, newsvendors' cries, &c. A recent local Act, which does not appear to be generally known (Liverpool Improvement Act, 1883), contains a section (29) which requires every street musician or singer to depart from the neighbourhood and from within hearing of any householders on being requested to do so by the latter, or any member of his family, or servant, or by any constable. A refusal to comply with this perfectly reasonable request renders the offender liable to a penalty of 40*s*.

CITY CHURCHYARDS.

This city contains within its corporate boundaries a large number of intra-mural churchyards and cemeteries which, since the year 1854, have been closed absolutely against all interments. Their appearance, until very recently, has been dismal in the extreme, presenting a dreary outlook of neglected graves and tombstones, while some have been made the receptacle for all the refuse of the adjoining street. Some years ago the incumbent of St. James's Church, Toxteth-park, the churchyard of which was in a most disgraceful condition, took steps to improve it, including the planting of trees. The experiment has proved both successful and contagious, other churchyards and cemeteries having been planted with trees and made into recreation-grounds. Another churchyard, St. Luke's, is now being laid out; and it is probable that in the course of years every intra-mural burial-ground will have been similarly transformed. This will conduce greatly to the health and comfort of the inhabitants in their neighbourhood.

THE ROYAL SOUTHERN HOSPITAL.

At the Royal Southern Hospital there are several cases of operation for the removal of new growths, under the care of Mr. Paul. A recurrent melanotic sarcoma of the neck, primary in a submaxillary gland, is worthy of note. The original growth was removed two years ago from a man aged forty-eight; he has since been in good health, but the recurrence was very extensive and deep, so that, although the wound is healing well, the ultimate prospect is not encouraging. Among the most interesting are two cases of carcinoma of the *antrum*, involving removal of the whole of the upper jaw and contents of the orbit. Mr. Paul refers to six cases of this nature which he has recently met with, all of them presenting the same clinical history, and one which enables the diagnosis from sarcoma to be made without reference to the microscope. In all, the first symptom noticed by the patient was a formation high up in the nostril on one side, which easily bled and gave rise usually to some unpleasant discharge; subsequently, at the inner angle of the orbit, a small soft tumour grew, displacing the eye, and this was the immediate cause of the patient's applying for admission to hospital. In no case was the antrum distended, as in sarcoma. The growth evidently began in the mucous membrane of the antrum, fungated into the nostril, and then spread up, probably along the nasal duct, to the inner angle of the orbit. Microscopically, two of the cases were of the ordinary squamous epithelioma, and the remaining four the normal cylindrical-celled carcinoma of this part. Both the patients have recovered temporarily from this extensive operation, but one already has a recurrence. An *epithelioma of the back* is another case not very common; and two old cases, come up to show themselves in good health, were encouraging—one, an excision of the rectum for cylindrical epithelioma nearly four years ago, still free; the other, a colotomy for the same growth in the sigmoid flexure of the colon six months ago. Mr. Paul has two cases of compound fracture of the leg into the ankle-joint, in which very good results have been obtained by treatment with his splint and wiring the bones; and two or three cases of talipes, in his splints, undergoing a gradual improvement.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

HEALTH LECTURES AT MORPETH.

A COURSE of six lectures of a popular nature has been commenced at Morpeth, and it is satisfactory to know that the public have taken a considerable interest in the matter, as evinced by an attendance which is said to have fully tested the capacity of the Town Hall. A few years ago a popular lecture by one of our professional brethren was a rare event in the North, and only "the leading men" ventured to address the public, and then on non-professional subjects as a rule. Now the younger members come forth, to the great advantage of the public, who desire, and will have, medical information and light on sanitary subjects. The first lecture was by Dr. David Drummond of Newcastle, and his subject, "House Sanitation," was ably treated, dwelling with force and lucidity on the importance of ventilation and drainage, and giving a number of very striking illustrations of how such diseases as scarlet and typhus fevers and consumption were generated by neglect of the principles laid down. The second lecture was given by Dr. Byrom Bramwell of Edinburgh (whom we claim here as a Tynesider); his subject, "Common Diseases, their Cause and Prevention," was very ably treated, and the Hall, if possible, was more crowded than on the former occasion. It is as well to mention, as bearing on the success of these sanitary lectures, that the experiment was tried, which has proved so successful, of charging one penny for admission to each lecture. This has been shown to be a better plan than free admission; for what people get for *nothing* they generally attach little or no value to.

THE CHLORAL HABIT.

A very distressing case has occurred in Durham City since my last letter. A lady, the wife of a prominent citizen, was found dead in her bed. It was stated at the inquest that she suffered from sleeplessness, for which she was in the habit of taking chloral without medical advice, and it was shown that death had taken place "from syncope, accelerated by chloral, self-administered."

AN EXAMPLE FOR TRAVELLERS IN SUNNY LANDS.

Sir George Elliott, Bart., M.P., has sent large boxes of beautiful flowers from the south of France to Durham County Hospital, Sunderland Infirmary, and Newcastle Infirmary, with instructions that they should be dispersed amongst the sick wards. Sir George has frequently shown his sympathy with the sick poor of the north before, but I venture to say this last act of his will be felt by them as most graceful and considerate.

MEASLES AND RÖTHELN IN THE NORTH.

There is now rather a smart epidemic of measles prevalent at Gateshead. I have heard of as many as forty pupils in one school being absent from this cause. Several adults have been attacked, and, as usually observed, have suffered more severely than children. Some cases have been evidently of the character of rötheln; but as a rule the epidemic has not shown the severity nor the fatality of the Sunderland outbreak, which, I regret to say, still prevails in a bad form in that borough.

TRIPLETS IN THE NORTH.

Since the New Year set in several cases of triple births have occurred in the north, both sides of the Tyne having received augmentation to their population in this way, and also some of the mining districts of Northumberland. If we suppose that the usual midwifery statistics are correct as showing triple births to take place once to every 6000 cases, we must allow that the experience of Mr. John Foggin, a young surgeon in practice here, has been quite unusual, for many practitioners will not have a case of triplets in a lifetime, while Mr. Foggin has had a case on January 8th last, two boys and a girl born alive; and again on March 28th, three boys born alive, and still living. I believe Mr. Foggin has been successful in obtaining the Royal Bounty for the first case, and is also hopeful of getting it for the last; both have occurred in the wives of poor and industrious people.

Newcastle-on-Tyne, April 6th.

PARIS.

(*From our Paris Correspondent.*)

THE SUSPECTED ARSENICAL POISONING CASE.

IN my letter of Jan. 31st I gave an account of a suspected case of poisoning by arsenic. The supposed criminal, whose name is Pel, and a clockmaker by trade, is soon to appear before the Court of Assizes of the Seine. The trial promises to be most interesting, and at the same time most perplexing, as the preliminary examination has been before the magistrates and medical jurists. Owing to the mysterious disappearance of the maid-servant of the accused man, a stove in which he is strongly suspected of having burnt the body of his victim, or perhaps victims, was seized; but as the dimensions appeared somewhat too small for the execution of his purpose, the medical experts had one made exactly like it, and by way of experiment burnt the corpse of a human adult in it. They were greatly surprised at the rapidity and completeness with which the body (previously cut up) was consumed. In fact, it might be used as a crematory. That belonging to the accused, which was rather primitive and unique of its kind, is supposed to have been devised by himself, and has been carefully preserved in the same condition as when found, as it will necessarily be brought forth as evidence against him. Although very small, yet the mouth of the stove was found large enough to admit a man's head, entire. It has also been noted that Pel followed very assiduously, and for a long time, the course of Medical Jurisprudence delivered by Professor Brouardel at the Morgue. Another crushing circumstance against the accused is that when the examining magistrate observed to him that arsenic was found in the body of his first wife, which was exhumed, he replied that that was not astonishing, as she had been treated for two years with arsenic; but it has been ascertained that none of the medical men who attended her had prescribed that substance, nor did any of the prescriptions made up at the pharmacies for her contain it.

REMOVAL OF A CANCEROUS KIDNEY.

Dr. Péan, one of the most daring French surgeons of the day, and a well-known ovariotomist, submitted to the Academy of Medicine last week the case of a patient (an English lady) from whom he had removed a cancerous kidney about fourteen months ago. Dr. Péan had seen the patient six years previously, but he did not then consider the case ready for any operative measure. She had in the interim consulted some of the most eminent surgeons in London, who declared, in response to her desire for an operation, that it was impracticable. She then came to Paris to consult Dr. Péan again, and when he saw her about fourteen months ago, he found her in the last stage of marasmus, and the tumour occupied as much of the abdomen as would a nine months' gravid uterus. The removal of the tumour was decided upon by gastrotomy, and the operation was effected by making an incision through the abdominal walls, along the linea alba from the pubes up to the epigastric region. The tumour was removed with some difficulty, and was found to weigh six kilogrammes, or about thirteen pounds, and the whole operation occupied a little more than an hour. It is, however, a pity that Dr. Péan did not mention whether the operation was performed under the influence of chloroform or other anæsthetic, or whether antiseptics were employed or not. Professor Charles Robin, who examined the tumour histologically, pronounced it to be an epithelioma of the kidney. Dr. Péan stated that, although the operation was performed about fourteen months ago, he did not then wish to submit the case to the Academy, as he was afraid of an early relapse. This, however, has not occurred; the general state of the patient has never failed to improve from the commencement, and the remaining kidney has been found sufficient to produce the normal quantity of urine. The urine of the patient was lately examined by M. Méhu, an eminent chemist, who declared that it was of the same chemical and histological constitution as that of women in health.

THE HEALTH OF THE ARCHBISHOP OF PARIS.

The Archbishop of Paris, who was reported to be suffering from bronchial catarrh, is now officially pronounced by his medical attendant to be out of danger, and notwithstanding his advanced age (his Eminence being an octogenarian), every hope is entertained of his recovery.

Paris, April 7th.

ANONYMOUS letters containing threats to blow up Netley Hospital with dynamite have recently been received by the Commandant and other officials of that institution. A few nights ago a package, which was immediately destroyed, was found in the vicinity of the hospital, and since then increased vigilance has been shown, and the force of military police stationed at the hospital has been increased.

THE ROYAL COLLEGE OF SURGEONS.

AT a quarterly meeting of the Council, held on Thursday last, the minutes of the last meeting were confirmed.

The thanks of the Council were given to Mrs. Fairlie Clarke for the presentation of drawings, &c., illustrating Diseases of the Tongue, which had been prepared by her late husband.

No essay was received for the Jacksonian Prize. The subject for next year is to be the Pathology, Diagnosis, and Surgical Treatment of Diseases of the Thyroid Gland.

Mr. E. H. Fenwick, of the London Hospital, was elected an Examiner in Physiology under the combined scheme.

The Committee of Charters and Bye-laws presented their report, the reproduction of which we must defer till next week. It was agreed that the Association of Fellows and Members be informed that the College is about to proceed to get the necessary charters and bye-laws drawn up.

The question of recognition by the College of the vaccination certificates granted at Belfast, having been again raised by a letter from Professor Redfern, was referred to a select committee.

A request from the Western University, London, Ontario, to have its teaching recognised, was referred to a committee of management of the two Colleges.

Mr. Durham gave notice of the following motion, to be brought forward at the next meeting of the Council: "That seven delegates from this College be appointed, with authority to invite an equal number of delegates from the Royal College of Physicians, to meet and confer upon what steps, if any, can be taken to enable the two Colleges to obtain the legal right of giving the title of Doctor to persons who shall have obtained the licence of the Royal College of Physicians of London, and the diploma of Member of the Royal College of Surgeons of England."

MAHOMED MEMORIAL FUND.

THE following additional subscriptions have been received:—

	£	s.	d.		£	s.	d.
Dr. Edward Chisholme (Sydney)	5	0	0	Albert Martin, Esq., M.B.	5	0	0
Dr. Arthur Evershed ...	1	1	0	T. D. Ransford, Esq. ...	1	1	0
H. Lund, Esq.	1	1	0	A. H. Tubby, Esq.	2	2	0

A meeting of the General Committee will be held in the Governors' Court-room, Guy's Hospital, on Thursday, April 16th, at 4.30 P.M., to receive the report of the Executive Subcommittee, and to consider how best to make use of the fund.

ARTHUR E. DURHAM, Treasurer.
JAMES F. GOODHART, } Secretaries.
W. H. A. JACOBSON, }

COUNTY COURT, CROYDON.

MEDICAL FEES FOR NECROPSIES IN WORKHOUSES.

In re DONBAVAN *v.* MORRISON.

MR. W. J. FRASER, who appeared for the plaintiff, having stated the facts, contended that it formed no part of the duty of the medical officer of the Croydon Wc and Infirmary to make a post-mortem examination of the deceased's body. The case was properly reported to the coroner's officer, who, having deemed an inquiry after consulting the coroner, the medical officer not being certain as to the actual cause of death, was ordered by the coroner to make a post-mortem. It was no part of such medical officer's duty to make such examination at the coroner's request. He was not remunerated for it. I prior to the appointment of the present (recently elected) coroner, his predecessor, Mr. Carter, had for years paid the fee. The workhouse and infirmary were not public tions within the meaning of the Act. They were exclus maintained at the expense of the ratepayers of the union and were for destitute persons and none others. Unl person was destitute, or in fact a pauper, there was no rig whatever on the part of such person to receive therein. No person could be treated in a workhouse infirmary without becoming a pauper. The plaintiff was therefore the medical officer of a pauper, and not of a public institution. A coroner had no more right to call upon the medical officer of a workhouse to make a post-mortem without paying the stipulated fee than he had to require the ordinary medical practitioner to do so, who might have been casually called in to attend upon a person upon whose body an inquest had to be held, and also a post-mortem. A public hospital or infirmary was an institution open for the reception of any person, no matter what might be his or her rank in society who sought its aid and could be cured therein. The word "public" was general in its application, and applied to all classes of persons, whereas a workhouse and infirmary was only for the pauper and no other. The word "public" meant public generally, and not any section such as the destitute and the pauper. In conclusion, Mr. Fraser saw that, whether the object for which the statute was passed, the mischief at which was aimed, the plain and natural interpretation of the language used, or the fact that workhouses were not mentioned or even referred to, was regarded, no other conclusion could be come to other than that the plaintiff was entitled to his fee, and it would be a manifest injustice to compel him to go without it, and to give that to him would be in accordance with the practice which had for the most part prevailed since the passing of the Act in 1841, and in harmony with the opinion of the Poor-law Board (now the Local Government Board), which was by no means an unworthy authority.

The judge, Mr. Lushington, gave a verdict for the defendant, with costs on the higher scale, alleging as the grounds for his decision that a workhouse infirmary was a public institution within the meaning of the section.

Mr. Fraser thereupon applied for a case for appeal, which the judge assented to.

Obituary.

JAMES WHITEHEAD, M.D., F.R.C.S.

We regret to record the death on the 3rd inst., at Sutton, Surrey, from cancer of the œsophagus, of Dr. James Whitehead, late of Manchester, in the seventy-fourth year of his age. The deceased, who was a native of Oldham, obtained his professional education at Manchester, Westminster Hospital, and Paris. In 1845 he obtained the diploma of Fellow of the Royal College of Surgeons of England, in 1850 the degree of M.D. from the University of St. Andrews, and was elected a Member of the Royal College of Physicians of London in 1859. He was also a member of various British and foreign scientific societies. Previous to its union with Owens College, Dr. Whitehead was lecturer on Obstetrics at the Royal School of Medicine, Manchester, and some years ago held the position of senior officer in ordinary at St. Mary's Hospital, and also that of Demonstrator of Anatomy. Amongst his published works are: "Diseases of the Uterine System," "Hereditary Diseases," "The Wife's Domain," "The Rate of Mortality in Manchester," and "Reports of the Manchester Clinical Hospital;" he also contributed various papers to the medical journals. In conjunction with the late Dr. A. Schoeff-Merei, Dr. Whitehead was a founder of the Manchester Clinical Hospital.

THOMAS HOWKINS, M.R.C.S.

Mr. Thomas Howkins died of heart disease at Torquay, in the fifty-fourth year of his age, on the 29th ult. His career as a medical student at University College, London, was a distinguished one. He gained, amongst other honours, the gold medal in Professor Erichsen's class of surgery; and, after obtaining the membership of the Royal College of Surgeons, established himself as a dental surgeon in Birmingham. Here he soon rose to leading practice, was appointed dental surgeon to the Children's Hospital, and more recently lecturer on Dental Physiology and Surgery at the Queen's College. For some years Mr. Howkins was one of the members of the Council of the latter institution; and when the local practitioners of dental surgery formed a Society for their specialty, Mr. Howkins was called to the presidential chair. His opening address was characteristic of him, as an accomplished surgeon and an eloquent speaker. He held one of the highest positions, as a philanthropic worker, in the Masonic brotherhood, and is sincerely mourned in a wide circle of devoted relatives and friends.

Medical News.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and *Practice* of Medicine, and received certificates to practise, on the 2nd inst.:—

Burd, George Frederick, St. Bartholomew's Hospital.
Rowlands, Thomas Frederic Watkin, Guy's Hospital.
Whitwell, Alfred Frank, St. Bartholomew's Hospital.

Dr. E. B. Truman has resigned his office as public analyst to the borough of Nottingham.

The eminent zoologist, Karl Theodore Ernest von Siebold, Professor at the Munich University, has just died at Munich.

Medical Magistrate.—Dr. Henry G. Thompson has been appointed a Justice of the Peace for the borough of Croydon.

Vaccination Grant.—Mr. W. Hood, of Castlegate, York, has received the Government grant for successful vaccination (third time).

On the 31st ult., the foundation-stone of the new sanatorium for Hull, now in course of erection, was laid by Dr. King, Sheriff of the town.

The Prince of Wales has consented to preside at a dinner in aid of the funds of the North London or University College Hospital, on May 13th.

An additional ward to the Birkenhead Corporation Fever Hospital was opened on the 31st ult. The erection has involved an expenditure of about £600.

It is stated that the first report of the Royal Commission on the Housing of the Working Classes has been agreed to, and that it is now in the hands of the Government printers.

The Shoeburyness Disaster.—A testimonial is to be presented to Mrs. Long, of the Prittlewell Sick Nursing Fund, upon whom rested the burden of nursing the sufferers from the late disaster at Shoeburyness.

Royal College of Surgeons of England.—At a meeting of the Council on the 9th inst., Mr. Edwin Hurry Fenwick, F.R.C.S. Eng., Assistant-Surgeon to the London Hospital, was elected Examiner in Elementary Physiology.

Arrangements have been completed for a "Conference on Education under Healthy Conditions," which is to be held in Manchester from April 14th to the 17th inclusive. The conference will be under the presidency of Lord Aberdare.

Parkes Museum.—A lecture was delivered in this institution on the 28th ult. by Mr. Fletcher, of Warrington, entitled "Smokeless Houses and Manufactories." The lecture was followed by a discussion, in which Dr. Coffin, Mr. Coles, and others took part.

In reference to the present movement to enlarge the Royal Surrey County Hospital, it has been suggested that the children's ward of the new wing might be specially termed the "Gordon Ward for Children," as a memorial of the hero of Khartoum.

At the recent annual meeting of the Margate Royal Sea-bathing Infirmary for Scrofula, the directors' report stated that the infirmary is approaching its centenary, and they appeal to the public for increased subscriptions in order that the iexpenditure arising from the recent extensions of the building may be met.

Society for the Study and Cure of Inebriety.—The annual general meeting of the members of this Society was held on the 7th inst., when the president, Dr. Norman Kerr, who occupied the chair, delivered an address, in the course of which he stated that the Association now numbered 279 members. A paper was then read by the secretary, Dr. W. M. Sturrock, contributed by Mr. Crother, of Hertford, Connecticut, honorary secretary of the American Society for the Study and Cure of Inebriety, entitled "The Incipient Stages of Inebriety." A discussion followed, in the course of which Dr. Farquharson, M.P., pointed out the difficulty of any legislative measures, and also asked for the results of the treatment in the Dalrymple Home for Inebriates. The chairman, in reply, stated that it was difficult to arrive at any satisfactory results from the statistics, as they had only been in existence for about a year; but that of the 49 cases treated in the Home, 50 per cent. of them had remained steadfast and had been restored to their ordinary careers, and 29 per cent. had been greatly benefited. The discussion was continued by Dr. James Stewart, Dr. Morton, and others.

Acting on the suggestion of a scientific journal in Germany, that neutral tints are beneficial to the eyesight, an enterprising publisher in that country has just issued a book printed in dark-blue ink on pale-green paper.

Prize Essays.—The following questions are selected by the Spanish Society of Medical Hydrology as subjects for prize essays, to be sent in by November, 1886:—1. Physical and Clinical Research on the Sulphuretted-Soda Natural Mineral Waters of Spain, and Comparison of Spanish Springs with the principal Foreign Springs. 2. Pathogenic conception of Pellagra, and its Mineral Water Treatment. The prize is £20, and the essays are to be written in Spanish, Portuguese, or French, and are to be signed with a motto only, and accompanied by a sealed envelope bearing the motto outside and the name and address of the author inside. The address of the secretary of the Society is Costanilla de los Angeles 13, Madrid.

Melbourne Hospital.—At the annual meeting of the governors of this institution on January 28th, it was stated that the total receipts during 1884 for the purposes of maintenance amounted to £24,302, and the expenditure to £23,277. The number of in-patients admitted was 3334, and of out-patients 13,009. The mortality in the wards was 16·7 per cent., more than one-fourth of the total number of deaths being due to phthisis; and the medical superintendent, in his report, having urged that provision should be made for the treatment of consumptives away from the metropolitan hospital, in the purer air of the country, it was unanimously resolved that steps ought to be taken by the committee of management to carry out the suggestions of the medical superintendent with reference to the removal of phthisical cases, either by establishing a separate institution in the country, or by arrangement with some other institution for their reception.

Royal College of Surgeons in Ireland.—At a special supplementary examination, held on Monday, March 16th, and following days, the following gentlemen were successful:—First Professional Examination: T. P. Connolly, C. D. Jones, R. Jones, J. H. Lovely, H. M'Carthy, R. Martin, T. O'Brien, E. O'Neill. Seven were rejected. Second Professional Examination: G. P. Carte, T. G. Goodman, C. M'Donnell, P. J. F. O'Brien, J. C. O'Donnell, J. O'Sullivan, A. V. Shine. Eleven were rejected. Third Professional Examination: W. A. Johnston. At the First Half Examination for the Letters Testimonial of the College, held on March 23rd and following days, the undermentioned gentlemen were successful:—J. A. C. Coen, A. R. T. Craig, I. Duncan, J. D. O'D. Egan, R. Elliott, E. W. Hamilton, J. C. Hines, A. M. Hunt, E. B. Kennedy, A. D. Macleod, A. E. Murphy, V. Nash, H. F. C. Pilcher, J. A. Scully, A. F. Smith, P. Stevenson, W. Stritch, W. Swan, W. E. Waters, J. A. Whitty, T. D. Wylie. Twenty-five were rejected.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Barrett, W. A. H., L.S.A.Lond., has been appointed Assistant House-Surgeon to the Royal Albert Hospital, Devonport.

Bourns, N. Whitelaw, M.D.Brussels, L.R.C.P.Ed., M.R.C.S., has been appointed Assistant-Surgeon to St. John's Hospital for Skin Diseases, vice Mr, Palmer, resigned.

Campbell, Charles M., M.D., C.M., L.R.C.S.Ed., has been appointed Assistant-Physician to St. John's Hospital for Skin Diseases, vice Dr. Boothby Dow, elected a Physician.

Dow, H. Boothby, M.D. St. And., M.R.C.S., has been appointed a Physician to St. John's Hospital for Skin Diseases, vice Dr. Oates, elected a Vice President.

Downes, Howard, L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the Victoria Hospital for Children, Chelsea, vice F. H. Hawkins, M.B., C.M., resigned.

Duncan, P. T., M.D., B.S.Lond., has been appointed Surgeon to the Croydon General Hospital.

Dunn, Hugh Percy, F.R.C.S.Eng. (Assistant Ophthalmic Surgeon), has been appointed Pathologist to the West London Hospital.

Glassington, Charles W., M.R.C.S., L.D.S. R.C.S.Ed., has been appointed Lecturer on Dental Materia Medica to the National Dental College, Great Portland-street.

Harrison, Edward, M.A., M.B.Cantab., has been appointed House-Surgeon to the Royal Infirmary, Hull.

Jackson, Henry, M.R.C.S., L.S.A.Lond., M.O.H., has been appointed Honorary Surgeon to the North Devon Infirmary, Barnstaple, vice Dr. Ferine, deceased.

Leicester, Ambrose William Montague, M.B., C.M., has been appointed Medical Officer for the Second District of the Eastbourne Union, vice Harold Arthur Tuxford, deceased.

Lyndon, Thomas, B.Ch.Dub., has been appointed Surgeon to the Wicklow County Infirmary.

Molyneux, Harold Joseph, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Upholland District of the Wigan Union, vice J. L. Molyneux.

Mortimer, J. D., M.R.C.S., L.S.A.Lond., has been appointed Assistant Medical Officer to the Portsmouth Borough Asylum, vice James Neil, M.D., C.M., resigned.

Murray, C. Stormont, L.R.C.S. &c., has been appointed Administrator of Anæsthetics to the Samaritan Free Hospital.

Pronger, Charles Ernest, L.R.C.P.Lond., M.R.C.S., has been appointed Honorary Surgeon to the North Devon Infirmary, Barnstaple, vice C. H. Gamble, resigned.

Sanctuary, Thomas, M.D., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Workhouse and Fourth District of the Alderbury Union, vice Gowing.

Wainewright, Benjamin, M.B., C.M.Ed., F.R.C.S.Eng., has been appointed Assistant-Surgeon to the West London Hospital, vice Albert Boyce Barrow, M.B.Lond., F.R.C.S.Eng., resigned.

Births, Marriages, and Deaths.

BIRTHS.

Gabbett.—On the 26th ult., at Gibraltar, the wife of Surgeon-Major Poole R. D. Gabbett, Medical Staff, of a daughter.

Hickey.—On the 5th ult., at the Royal Naval Hospital, Esquimalt, British Columbia, the wife of Staff-Surgeon L. Canning Hickey, M.B., of a daughter.

Hunt.—On the 3rd inst., at Queen's-road, Dalston, the wife of Joseph W. Hunt, M.D.Lond., of a son.

Illingworth.—On the 31st ult., at 1, Crowther-terrace, Clayton-le-Moors, the wife of C. R. Illingworth, M.D., of a daughter.

Paramore.—On the 1st inst., at Hunter-street, Brunswick-square, W.C., the wife of Richard Paramore, M.D., of a son.

Richards.—On the 1st inst., at 38, Arundel-square, Barnsbury, N., the wife of C. C. Richards, M.D., of a son.

MARRIAGES.

Champ—Schaeffer.—On the 4th inst., at Holloway Chapel, London, John Howard Champ, M.D.Lond., son of J. Champ, Esq., of Chelmsford, to Josephine, eldest daughter of the late Joseph Schaeffer, of Heidelberg.

Dunlop—Galt.—On the 8th inst., at the Alexandria Hotel, Bath-street, Glasgow, by the Rev. Fergus Ferguson, M.A., of Queen's-park U. P. Church, and the Rev. D. W. Forrest, M.A., of Hamilton, Thomas C. Cameron Dunlop, M.B., C.M., of Newmilns, Ayrshire, to Amy, second daughter of W. M. Galt, Esq., of The Brook, Enniskillen, Ireland.

Yeatman—Browne.—On the 12th Feb., at St. Luke's Church, South Melbourne, by the Rev. R. B. Dickinson, John W. Yeatman, M.R.C.S.Eng., son of the Rev. E. K. Yeatman, M.A.Oxon., of Auburn, South Australia, to Katherine Maude, fourth daughter of the late John E. Browne, of Northcote, Melbourne.

DEATHS.

Bond.—On the 2nd inst., at Mentone, France, George Weddall Bond, M.R.C.S., third son of the late Rev. R. Bond, Rector of Pulham St. Mary the Virgin, Norfolk.

Howkins.—On the 20th ult., at Torquay, Thomas Howkins, M.R.C.S., late of Bennett's-hill, Birmingham.

Pope. — At South-crescent, Bedford-square, Joseph John Pope, M.R.C.S.

Sankey.—On the 27th Jan., on board the *Chimborazo*, in the Red Sea, from inflammation of the lungs, George Sankey, M.R.C.S. & L.S.A.Lond., of Maidstone, aged 54.

Sturge.—On the 2nd inst., at Rue Longchamp, Nice, Emily Bovell Sturge, M.D.Paris, Officier d'Académie, daughter of the late John Roache Bovell of Demerara, and wife of William Allen Sturge, M.D.

Whitehead.—On Good Friday, the 3rd inst., at his residence, Fairlands, Sutton, Surrey, James Whitehead, M.D., late of Mosley-street, Manchester, in his 74th year.

Wilkie.—On the 3rd inst., at Paris, David Elliot Wilkie, M.D., of Rathobyres, third son of the late Rev. Daniel Wilkie of Rathobyres, Minister of New Grey Friars, Edinburgh.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 13.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Mr. J. Bland Sutton: Injuries and Diseases of the Jaws in Wild Animals.—Casual communications by Messrs. W. A. Hunt, Wenland Pedley, A. S. Underwood, and F. H. Weiss.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Whipham: A case of Myxœdema with the Microscopical Appearances of some of the Organs.—Dr. Hughes Bennett: A case of Brachial Monoplegia due to a Lesion of the Internal Capsule.

Tuesday, April 14.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Dr. J. G. Garson: On the Inhabitants of Tierra del Fuego.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Lunn and Dr. Benham: Case of Aneurysm of Abdominal Aorta, distal compression for four hours and three-quarters under chloroform, cure of aneurysm, death from gangrene of jejunum on the eleventh day.—Mr. Henry Morris: A case of Aneurysm of the Abdominal Aorta leading to Gangrene of the Lower Extremity.—Dr. Beevor: Two cases (Progressive Muscular Atrophy and Infantile Paralysis) illustrating the Localisation of Motor Centres in the Brachial Enlargement of the Spinal Cord.

Wednesday, April 15.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—3 P.M. Mr. R. Brudenell Carter: Eyesight in Schools.

Thursday, April 16.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Tyndall: Natural Forces and Energies.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. R. W. Burnet: Cases of Ulcerative Endocarditis, with remarks.—Mr. J. Ernest Lane: Hæmophilia.

Friday, April 17.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. The Council will present a report on the Rivers Pollution Bill and the Water Companies Regulation of Powers Bill.—Dr. Thomas Stevenson: Sewage Disposal.

ROYAL INSTITUTION.—9 P.M. Prof. S. P. Langley: Sunlight and the Earth's Atmosphere.

Saturday, April 18.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. W. Carruthers: Fir-trees and their Allies.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

NEW FARINACEOUS SEED.

A LETTER from M. Saco of Cochabamba to the Paris Academy of Sciences reports upon a new alimentary substance the composition of which is remarkable. The seed which is richest in nitrogenised substances is that of the Bolivian cotton tree. Its analysis shows 23·70 per cent. of fibrine and 6 per cent. of caseine. When ground, there is only 3 per cent. of loss, a yellow flour being 56¾ per cent., and a black bran 40¼ per cent. M. Saco remarks that this flour ought to be particularly suitable for pastry, as it would to some extent replace milk. It is also of service in sugar manufacture, as a substitute for carbonic acid. It is likewise good for sweets, &c. As the production of cotton seed is very large, its utilisation would be of great alimentary importance.

Dr. C. Morfit.—We will try to find a place for the article in an early number.

"EFFECTS OF HANDLING DYNAMITE."

To the Editor of THE LANCET.

SIR,—Surgeon-Major Colson's letter on this subject reminded me of having read of the same thing before; and on referring to my notes I find that Dr. Colquhoun (*Australian Medical Journal*, June, 1881) found symptoms of this kind result, as he believed, from the vapour of imperfectly consumed nitro-glycerine in the air of mines where dynamite was used, and that Dr. R. B. Nevitt (*Canadian Journal of Medical Science*, February, 1882) reported the case of a man aged forty, a contractor, in the habit of using dynamite cartridges, who suffered from headache, tinnitus, and palpitation, which symptoms disappeared when he took the precaution to wear gloves and avoided a previous trick of tasting his fingers with his tongue to see if all the dynamite was washed off. I think it is very doubtful if nitro-glycerine acts through the skin or the atmosphere; and I would suggest that the utmost caution should be used to prevent actual contact of the dynamite with the eyes or mouth, which may easily occur if the user is not forewarned of the danger.

I am, Sir, yours obediently,

ROBERT SAUNDBY, M.D.

Birmingham, April 4th, 1885.

To the Editor of THE LANCET.

SIR,—In reply to Surgeon-Major Colson's note, "dynamite headache," as it is called, is very similar to that produced by amylic nitrate, and, so far as I know, is inseparable from the use of the explosive, until immunity is produced either by prolonged use or idiosyncrasy; but no permanent injury results. With regard to the cure, there is none, except cessation from working with it; but brandy-and-water will mitigate it, and sleep generally remove it. Some physiological notes were published in THE LANCET some time ago.

I am, Sir, yours faithfully,

WALTER WICKHAM.

Surgeon to Nobel's Explosives Co., West Quarter Factory.

Polmont Station, N.B., April 6th, 1885.

THE INDEX MEDICUS.

As announced in a recent issue, the publication of the Index Medicus will be continued by Mr. G. S. Davis of Detroit. On account of the delay required to perfect the new arrangement, the first number of the journal for the current year will comprise the literature of January, February, and March, after which it will appear monthly as usual. At the end of the year, in addition to the usual annual index of names, subscribers will be furnished with an index of subjects to the volume.

A Constant Reader.—A patient suffering from a *small* irreducible strangulated femoral hernia is better without a truss, as the pressure tends to cause inflammatory adhesion and constriction of the bowel, and so increases the danger of internal strangulation. The case as described by our correspondent reads more like one of incarcerated (obstructed irreducible) than strangulated hernia. That being so, enemata (not purges), spare liquid diet, local application of ice, and complete rest constitute the appropriate treatment. In most cases of strangulated hernia, unless gangrene of the bowel is feared, it is customary to attempt reduction under an anæsthetic before resorting to the more severe operative procedure; and this rule applies with greater force to obstructed hernia. At the same time, each case must be judged on its merits.

A. B. C.—Wooton's Guide to the Medical Profession (U. Gill, Strand, London) would assist our correspondent.

Beta.—Yes, in an early number.

"APPLICATION OF MIDWIFERY FORCEPS."

To the Editor of THE LANCET.

SIR,—I should be the last in the world to despise the aid given by forceps in cases where they are really necessary, but I think there is a growing tendency among general practitioners to shorten labour by means of the forceps, especially if they be adepts in the use of the instruments. How many women there are who have to thank their impatient medical attendant, in, say, a first confinement, for a perineum ruptured into the anus—a life-long discomfort! The doctor is rarely blamed; as a rule, a woman is only too glad to get over her troubles at any price, and the medical attendant is lauded "to the skies" for his cleverness in bringing matters so quickly to an apparently successful issue. Further, I would ask those who make the diseases of women a specialty, how many of the various flexions of the uterus are due to the application of the forceps? and, again, how much their use conduces to malposition of the organ? I *cannot* but think that many of these troubles are due to the meddlesome, nay wicked, interference with what nature would successfully accomplish, and very much better than the doctor. In this opinion I am supported by the fact that uterine troubles in the rural districts are very rare in comparison with those existing in town practice, nature, not the doctor, doing the work.

It is argued by many that deformities in women are more common than they were formerly. I, for one, consider that Englishwomen of the present day are as well developed and as capable of going through maternity naturally as their grandmothers were. It is an easy matter, however, to point out errors, but to apply the remedy is more difficult. But here the remedy lies in ourselves, our own judgment, and the recollection of what is due to those who place themselves with such trust and confidence in our hands.—Yours faithfully,

W. AYLMER LEWIS, F.R.C.S.

Willow-street, Oswestry, April 7th, 1885.

To the Editor of THE LANCET.

SIR,—With reference to the above subject, permit me to describe a method of applying the forceps which I have adopted and practised for many years. I apply the lower blade first. The patient's right knee is then drawn up, and the left leg extended and drawn outwards. The upper blade is then introduced, using the left hand, the forefinger of the right hand being in the vagina to direct the blade over the head and gently press the convex edge of the blade. In this way it easily goes into its proper position and locks with the other. Extraction is then made in the ordinary manner.—Your obedient servant,

Kingussie, March, 1885. J. C. ORCHARD, L.R.C.S. Edin.

B. will see that the subject to which he has been so good as to direct our attention has not escaped our notice.

T.—Bath or Buxton.

AN OLD MEDAL.

To the Editor of THE LANCET.

SIR,—I should feel much obliged to any of your correspondents who would give me information as to a medal in my possession, of which the following is a description: Diameter 1¼ in. Obverse—A pot of flowers in high relief, standing on a label, on which is the date, also in relief, 1684, and engraved on the label, evidently prepared for that purpose, the inscription, "MR. JOANNES . DE . WALL." In the exergue are the words, 'HORTUS MEDICUS." Reverse—A skeleton with scythe and hour-glass, standing in a flowery mead. The botanic gardens in Chelsea (commonly called the "Physic Garden") were not enclosed till 1686, so that a ticket of admission, which this medal evidently is, would have no *raison d'être* in 1684. Yet, I feel no doubt that its design and execution are English.

I am, Sir, yours obediently,
M. U.

April 6th, 1885.

THE RUPTURE OF BLOODVESSELS.

MM. GRÉHANT and QUINQUAUD have reported to the Paris Academy of Sciences their experiments proving that the pressure necessary to cause the rupture of arteries is much greater than that to which they are normally subjected. The carotid artery of a dog required from thirty-five to fifty-five times the normal pressure of the blood, and the jugular vein from thirty-two to forty-five times the usual force.

Practitioner should remonstrate with the chemist, and, failing to get satisfaction, should complain of his conduct to the President of the Council, who is at present trying to regulate the sale of poisons by legislation.

"VEGETABLE FOOD FOR CHILDREN."

To the Editor of THE LANCET.

SIR,—Perhaps you will allow me to make a remark or two upon your notice under the above heading of the dinner given by Mr. S. Morley, M.P., under the auspices of the National Food Reform Society. The dinner mentioned was given with a view of showing the people of Leigh that a good dinner could be provided at small cost and yet be pleasing, wholesome, and sufficient. The menu was "Scotch broth," "lentil sandwiches," "lentil fritters," with cauliflower, potatoes, and "brown sauce," "Albert pudding," with white sauce. Whole wheat-meal bread was also given. The entire cost of dinner (for food) was under fourpence halfpenny per head. Mr. Morley and all to whom I have spoken have pronounced the dinner as having been first-class in every particular, and a good lesson in practical thrift.

In regard to non-flesh eaters being non-drinkers, I may mention that previously to my giving up "meat" I was fond of "a glass," but in three months I lost all desire or taste for strong drink. I could say much on the head of experience, as I have now been an abstainer from "meat" for upwards of seven years, and I have lost many of my former complaints. I may say that I am quite willing to place myself in the hands of any medical gentleman for the purpose of experiments in dietetics, and that without any compensation whatever. In conclusion, allow me to state that the National Food Reform Society will give its thrifty dinners when asked so to do, provided a hall, &c., is furnished free of cost. I am, Sir, yours faithfully,

F. P. DOREMUS.
Hon. Secretary, National Food Reform Society.

Finsbury-square Buildings, E.C., April 4th, 1885.

⁂ While we cannot agree that vegetarianism is a sound enough principle in dietetics to be generally adopted, we freely admit that an occasional change of fare of this kind is both wholesome and agreeable. Some persons also, even adults, thrive better, as a rule, on vegetable than on animal diet; or, at all events, on a diet in which vegetables markedly predominate. Such are those of gouty constitution. With regard to the effect of food on the liking of alcohol, no conclusion, we think, can yet be arrived at. Possibly the flavour of fruit may satisfy some as a substitute for its more potent derivative.—ED. L.

NURSING STATISTICS.

M.D. asks: "Will any of your readers oblige by referring me to a source of information regarding the cost of nursing (apart from other sources of maintenance) in the large general hospitals of the metropolis and the provinces."

E. De Manin.—There is no particular objection to gas-stoves, so long as proper provision is made for carrying off the products of combustion.

RECREATION FOR THE SOLDIERS IN THE SOUDAN.

To the Editor of THE LANCET.

SIR,—You were good enough to put a paragraph in THE LANCET of March 21st, saying that I would be glad to receive contributions of suitable literature for the soldiers in the Soudan. I now desire to thank the public, amongst whom are a few medical men, for the parcels they have sent; and as they have a right to know what I have done, I may say that since March 21st I have sent 5 cwt. of books, dominoes, draughts, and a few pipes to Suakim, about 4 cwt. to Dongola, and about 4 cwt. to Wady Halfa, and I think I shall be able to forward about 4 cwt. next week. I know from experience how a newspaper, six weeks old even, is valued in such a place as the Soudan, and consequently have some feeling for our brave soldiers who are now fighting our battles and suffering all manner of privations. Those who have kindly sent parcels please accept my thanks. I am, Sir, yours truly,

258, St. Philip's-road, Sheffield, April 4th, 1885. JOSIAH WILLIAMS.

THE DEBATE ON CHOLERA.

Mr. J. B. Scriven writes that the report of his remarks on cholera in our last issue, page 616, is incorrect. His argument as to the cause of the viscidity of the blood may be stated thus: The almost unlimited power of absorbing fluid which the blood possesses during health has not been proved to continue in full force during an attack of cholera; so that in that disease much of the water discharged in the stools may possibly not be replaced in the blood.

Calyx.—1. No; choice should be made beforehand.—2. In London, two or three days before the examinations begin.—3. We are not aware of their having been published.

ILLEGIBLE PRESCRIPTIONS.

A CORRESPONDENT from West Australia has forwarded us a prescription which, written by a brother practitioner, was handed in to his dispenser to be made up. The writing is so bad, and the figures denoting the quantity of each drug to be used so blotted and confused, that the medicine could only be made up by the knowledge of doses possessed by the dispenser. This fault of writing, through haste or carelessness, illegible prescriptions is one shared by many medical men; but it is nevertheless a grave one, and one that has frequently ere now led to serious consequences.

J. J.—A burn which destroys the skin, superficial fascia, and muscles must necessarily be followed by profuse suppuration and cicatricial contraction. The one described could not by any possibility have healed in a month. Where home comforts and careful nursing can be obtained, we consider the patient best treated out of hospital.

E. H. should consult his medical attendant.

Ixion.—We do not give advice.

MEASLES IN GUERNSEY.

To the Editor of THE LANCET.

SIR,—I hope I am not in error in accepting your note under the above ading in your last issue as an invitation to make a personal explanation. At the end of the Table of Contents in each issue of the *Glasgow Medical Journal* the following notice appears:—"Authors of original rticles may, by applying to the printer, obtain twenty-five reprints of heir articles gratis, and additional copies at a small cost." I obtained the twenty-five copies, and detail for your information the distribution which took place in Guernsey. Drs. Corbin, Crewe, Constantine, Conclean, Glasse, Thornhill, three personal friends (none of whom can be referred to by your correspondent) who furnished me with statistics concerning the number of cases in the schools, and the following officials: the Lieut.-Governor of Guernsey, the Bailiff of Guernsey, the Chief Constable of Guernsey, and Dr. Le Page, each received a copy of the *Journal*. I defy your correspondent to supplement this list. The copies sent to the Lieut.-Governor, the Bailiff, and the Chief Constable were sent officially, and were marked, as the enclosed copy is, on pages 2 and 3, directing their attention to the comments there on the sanitary condition of the place, a subject which has occupied them much during the past winter, and on which medical opinion was invited. The Lieut.-Governor and the Chief Constable are not patients of mine, and they received their copies addressed to them as officials at their offices.

The allegation that the recent epidemic of measles differed from the description given of it in my paper will not be much credited in Guernsey. Only those who failed to observe, or were blinded by prejudice, could make a contrary statement.

I am afraid that your notice will render it difficult for me to keep my comments on the sanitary condition of the town within the official limits which I had intended even until my reply reaches your columns. The statements made in my paper are well known to be correct, and could only have done public good while their distribution was limited to those concerned in the local sanitary administration.

I am, Sir, your obedient servant,
J. AIKMAN.

Guernsey, April 4th, 1885.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an extract from THE LANCET of the 4th inst., in which exception is taken to Dr. Aikman's action in sending copies of his paper in the *Glasgow Medical Journal* on the Epidemic of Measles in Guernsey to the patients of another medical man. As I received a copy of his paper from Dr. Aikman, and may be one of the recipients alluded to, I ask your permission to state that I, as Lieut.-Governor of Guernsey, have publicly interested myself in the sanitary state of the island, and have no idea that the paper was sent to me except in my official capacity.

I have the honour to be, Sir, your obedient servant,
H. A. SAREL, Major-General.
Lieutenant-Governor of Guernsey.

Bournemouth, April 7th, 1885.

To the Editor of THE LANCET.

SIR,—At Dr. Aikman's request, I hereby beg to state that I received a copy of the reprint of his notes on a recent epidemic of measles in Guernsey, addressed to me at the Constable's Office in my official capacity; also that the copy was marked at the passages referring to the sanitation of the town.—Yours faithfully,
JULIUS A. CAREY, Chief Constable.

Guernsey, April 4th, 1885.

⁂ We think Dr. Aikman's letter satisfactory. Moreover, we have read the paper on Measles, and cannot see anything in it to justify the complaints made. The epidemic had been very extensive and rather severe, and was the more noticeable as being rare in the island.—ED. L.

PREVENTION OF CARBUNCLE IN CATTLE BY VACCINATION.

To the Editor of THE LANCET.

SIR,—I should be much obliged if any of your readers could tell me where I can get lymph for "vaccinating" cattle as a preventive against carbuncle. I believe Pasteur is the discoverer of the method and preparation.

I am, Sir, your obedient servant,
F. G. V.

April 7th, 1885.

WHOOPING-COUGH.

Mr. C. Clark Burman, L.R.C.P. & S. Ed. (Belford, Northumberland), solicits replies to the following questions:—(1) Are the paroxysms of whooping-cough more frequent always at night, whether the patient sleeps or not? (2) At what hours of the night are they most apt to occur? (3) What relation do they bear to the sleep of the child—i.e., during profound sleep or otherwise? (4) What circumstances appear to induce them?

Mr. W. Holderness.—1. Berkeley Hill's work on Bandaging and Minor Surgery.—2. Lewis S. Pilcher's Treatment of Wounds. The latter, an American work, is one of the best on the subject with which we are acquainted. It is published by Messrs. William Wood and Co., 56, and 58, Lafayette-place, New York.

THE BIRMINGHAM MEDICAL INSTITUTE.

To the Editor of THE LANCET.

SIR,—The interesting account, given in to-day's issue of THE LANCET, of the Birmingham Medical Institute, ought to make one glow with pride at having the privilege of living even within two or three miles of such a noble and generous Society. But, Sir, there is another side to the picture, and this, I am sure, out of regard for your time-honoured maxim, *Audi alteram partem*, you will allow me to present with the pen of a truthful but not unfriendly critic.

Rather more than a year ago a "registered practitioner" applied to the sub-librarian of the above-named Society for information as to the steps to be taken to enable him to avail himself of the library. He was told by that official that the payment of a guinea was the chief thing required, although there was another ceremony to be observed, which, however, was a "mere form." The ceremony thus described as a "mere form" was the signing by six members of the institute of a paper left in the reading room for that purpose. The "registered practitioner" paid the fee, and in due course two signatures were affixed to the paper. Then in a short time the document disappeared altogether, leaving the "registered practitioner" to believe that the "mere form" had been duly complied with. His surprise, however, was great when, three months afterwards, on applying for a book, he was told that he was not a member. On further inquiry he learned that the signatures referred to had been withdrawn at the dictation of a "distinguished hospital surgeon," who had forbidden his name to be divulged. I regret to say that the "registered practitioner" lost his temper on this occasion, though I do not much wonder that he yielded to this infirmity. To have been blackballed by a ballot would have been intelligible, and timely notice would have been given of the result; but the above-described method of procedure seems both ill-natured and illiberal. The "registered practitioner" has no complaint to make against the officials of the Society, either honorary or paid, but he would like to see the "distinguished hospital surgeon" emerge from his Olympian cloud and give some explanation of his conduct.—Yours obediently,
WILLIAM J. NOTLEY, M.D.

Birmingham, April 4th, 1885.

F.R.C.S.—Reports from Her Majesty's Representatives at European Courts and in the United States on the Working of the Lunacy Laws in the Countries in which they reside. Miscellaneous, No. 1 (1885). Messrs. Hansard, 13, Great Queen-street, W.C.

Mr. E. Playter.—We do not think it would serve any good purpose to open the discussion our correspondent suggests. There can be no doubt of "the present usefulness of the practice."

"A HALFPENNY A WEEK."

To the Editor of THE LANCET.

SIR,—In answer to an annotation under the above heading, which appeared in your issue of March 21st, the Committee of the Working Men's Medical Society at Sheerness would like to correct the serious errors made in that statement. As to there being some sixty applicants who applied for the position as advertised in THE LANCET of March 7th, it is due to them and others to know that the working men of Sheerness did not expect a medical gentleman to work on such unremunerative terms as appeared in the paragraph alluded to. A similar Society to ours has been in existence this past forty years; it is true our contribution is only one halfpenny per week, but it is for each individual entered, which on a little consideration will show that the scheme is very feasible. Let us give a short digest of how our Society now stands, and we think it will conclusively show the different gentlemen who applied that what we stated in our advertisement was more than correct.

The Society was inaugurated on March 1st, 1885; our present number of members (March 29th) is about 3300, which gives £411 per annum, the accouchement fee for members' wives are paid in addition to these contributions, which would equal another £150, making a total of about £560 per annum; private practice is also allowed. None of the above amounts are deducted for working expenses.

In reference to the paragraph alluding to the Portsmouth Association, it was stated at the meeting that they paid their doctors about £300 and £400 per annum each, and not, as represented, that amount divided between them. We hope this statement will satisfy those gentlemen who have written to us on this subject since the erroneous insertion of March 21st.

I am, Sir, yours respectfully,
THOS. LOVATT, Secretary.
For the Committee of the Working Men's Medical Society.

Marine Town, Sheerness, April 6th, 1885.

under the great division of inland climates, the third under marine climates. In rapidly glancing over these divisions, I shall have the opportunity of mentioning some other localities which are used as health resorts in phthisis, although they could not claim pure air, or air of an aseptic character, as one of their prominent features.

Allow me, gentlemen, to begin with the climates of elevated regions (altitude or mountain climates), *which only in comparatively recent times* have come into favour in Europe; although they were used in Peru at an earlier period (Archibald Smith). They were somewhat roughly treated in the beginning. A justly esteemed author on diseases of the lungs, for instance, in 1871 calls the plan of treating consumptive patients by long residence in the Alps "a startling quasi-sensational novelty in climatic therapeutics" in reference to a paper of mine "On the Treatment of Phthisis by Prolonged Residence in Elevated Regions" in the Medical and Chirurgical Transactions of 1869. In further discussing this plan the same author speaks of the winter in an "elevated site in Switzerland" as a sojourn "amid mist, fog, *damp, the fiercest cold, frost, ice, and snow.*" Surely, great physician though he is, he is somewhat misinformed on this subject, and has not himself visited the High Alps during winter, but has possibly formed his impressions from a writer who practised during winter in Southern Italy. I shall discuss the author's objections *seriatim*, as this will show the character of the climate.

1. The "mist" and "fog" amid which he imagines the patient to be during winter in the High Alps exist, indeed, only in imagination. They are at all events excessively rare in those high valleys in winter, and when Zurich, Berne, and Basle are for days together wrapped in dense mist, the sky is most blue in the High Alps, and the air *perfectly transparent and transcalent.* M. Billwiller, the head of the Meteorological Department in Switzerland, has quite lately organised a system of recording sunshine at different meteorological stations, and I have, by chance, before me the comparison between Zurich and Davos, during the months of last November and January (having mislaid the number for December). At Zurich the amount of sunshine during the month of November was 48½ hours, or an average per day of 1 hour 36½ minutes; ditto at Davos, 128 hours, or 4 hours 16 minutes per day. During the month of January at Zurich the recorded sunshine was 37 hours, or 1 hour 11 minutes per day, the same at Davos, 137·8 hours, or 4¾ hours per day. All those authors who are thoroughly *acquainted with the winter in the Alps, as Spengler, Waters,* Frankland, Ludwig, Volland, Addington Symonds, Theodore Williams, and Jaccoud, amongst others, have described the absence of mist and the abundance of sunshine, and it is only a corroboration of their statements, when I add, that while at Zurich and in the whole of the lower regions of Switzerland a thick mist entirely shut out the rays of the sun from the 18th to the 27th of January last, 6 hours of sunshine were registered daily at Davos, and what kind of sunshine this is the dwellers in the *lower regions who have* never been in the High Alps during winter can scarcely imagine. At the end of November, 1869, I spent on the Piz Languard, about 10,700 feet above sea level, and on an ice pyramid of the Morteratsh glacier (about 9700 feet) more than 1½ hours on two consecutive days without an overcoat. *As long as I remained in the sun I* never felt warmer in August and September at the same localities, but in the shade an overcoat would have been just a comfort, though I did not feel cold in spite of a temperature of only 20° to 25° F., the air being perfectly calm. A black bulb thermometer *in vacuo* showed in the sun between 88° and 92° F., while an ordinary thermometer showed only between 31° and 32° F., and the exhaled breath became rapidly condensed. This shows that the air itself was only slightly heated by the sun's rays, though the body covered with woollen clothes had all the benefit of the warming rays. I specially mention this difference between the black bulb and the ordinary thermometer because it shows that the air inhaled is cold, to which point I shall later return. During these two days a dense mist prevailed in the lower part of Switzerland and Upper Italy.

2. *How can the author call the air damp, and how has he* obtained this notion? Dr. Frankland speaks of the "excessive dryness of the air at Davos," and further on says, "The absence of suspended watery particles in the air has no doubt very considerable influence in preventing the chilling of the skin." I need only consider the facts that air at a low temperature can hold only a very small quantity of watery vapour, and that *if that small maximum is reached* the vapour must become condensed in the shape of mist or fog, the rarity of which I have already mentioned; and the usual transparency and transcalency show likewise that the quantity of suspended vapour can be only very small. All the authors agree on this point, and Dr. Volland and Mr. Waters have further pointed out that also the air in the *rooms is very dry, indeed, even drier than out of doors.* Mr. Waters found the relative humidity in his bed-room at Davos during the winter 1881-82 varying from 25° to 35°; the temperature of the room being about 60° F. with an open window at night.

3. "The fiercest cold and frost" of which our author speaks is scarcely felt by the patients at Davos or St. Moritz; Spengler, Waters, Frankland, Unger, A. Symonds, Theodore Williams, Ludwig, Rohden, Peters, and myself, as well as many others, have often discussed this question. The main points which prevent the cold being much felt are:—(1) That the air is dry; (2) that it is calm; and (3) that the sun heat is very great. In an excellent article in a recent number *of the Practitioner on "Winter Health Resorts" the same* question is discussed. "The temperature of the human body depends very much on the dryness of the air. A Canadian feels it much colder at 4° below freezing-point in London than in Canada when the thermometer stood at 40° below zero. The dryness of the air in Canada more than compensates for a difference of 68°. Dry air has very little capacity for heat, so that when it is at rest it conducts away very little heat from the body." Wind changes the matter very considerably; but wind, as I have said, is rare during winter in the chief Alpine health resorts; partly through the shelter of the mountains, partly through the absence of local winds, as every place is covered with snow. *In summer there is much more wind, and it is then often very* disagreeable, and unless care is taken chilling; but it is not so injurious as it would be in winter. I have spoken already of the great sun heat, and the papers of Waters, Frankland, and others are well known. The result of this sunshine and absence of wind is that even rather delicate invalids can sit for many hours lightly covered on open terraces and in verandahs, or on seats, along the southern slopes of the mountains or round the ice-rink; that they can frequently drive in sledges and take short walks; *while the hardier* ones can join in long excursions, in skating, and tobogganing; the time passes quickly and the majority of invalids manage to be more in the open air than on the Riviera. Is the calm, dry cold of the Alpine winter health resorts injurious? My answer is decidedly, No. It is not only not injurious, but beneficial to all those who are suited to this climate. When warmly dressed, *the invalids who are able to walk can be* out, even if there is no sun, provided there is no strong, cold wind; and the majority of them can with reasonable precautions in dressing even walk on calm evenings. The danger of becoming chilled at the time of sunset is far less than in the Riviera climates. It is only a remnant of our old *prejudice which can make us afraid of dry, calm, moderate* cold. A consumptive patient is in a better condition for recovery if he lies on a couch in a judiciously selected spot in the open air even in winter than in a shut-up room. The low temperature of the air has the obvious advantage that the bacillus and other microbes cannot thrive in it, and that putrefaction is arrested. In addition to this, the low temperature of the inhaled air leads to loss of heat, and of a large amount of water. This, I presume, acts as well in an antiphlogistic as also in an antiseptic way; and it may arrest the disease by drying up a sore and by checking the thriving of the bacillus within the lungs. The diminution of the expectoration observed in many cases is partly due to it, and, perhaps, also that of the night perspiration. The pulmonary circulation becomes increased, in order to supply the water lost, and the energy of the right heart, and of the cells and tissues of the lungs, must be likewise favourably influenced. The respiratory thoracic movements cannot escape being rendered more active, and through this expansion of the thorax, strengthening of the thoracic muscles and a help to all the respiratory acts. It is not too much to say that a great part of the favourable influence of the winter climate of the High Alps takes place through the increased inhalation of *this cold,* dry, pure, and rarefied air.

4. I fully acknowledge the author's correctness with regard to ice and snow in the winter climate of the High Alps, but *with this I find as little fault as with the calm cold air.* Indeed, they are almost inseparable, for the ice and snow

which cover the ground prevent dust and decay, and the microbe laden emanations from the soil. The calmness of *the air, the absence of local winds* ("Thal" and "Berg" winds), are in great part due to the ground being covered with ice and snow; furthermore, where the roads are for months together covered with snow, the invalid can walk on them without the danger of wet feet, and the healthful *exercises of sledging, tobogganing,* and *skating* for the more hardy invalids and their companions are certainly not to be despised.

After having discussed the bad character of our author's Alpine winter I must devote a few minutes to the purity and rarefaction of the air. The *purity, or aseptic character,* is intimately connected with the cold, ice, and snow, and also with the sparseness of population and industries. To this point, and particularly to the comparative absence of spores, I had always been inclined to ascribe the favourable influence of residence at high elevations on phthisis; and when Professor Tyndall in 1868 directed my attention to Pasteur's researches, published in 1862, I became strengthened in this view, which I mentioned at the Medical and Chirurgical Society in 1869. The facts published by Miguel, and already quoted above, as to the absence of microbes in the Alps at localities above 2000 metres, strikingly show the purity of the air. I am not, however, blind to the fact that wherever a large number of human beings, especially invalids, congregate, there the purity of the air is likely to be impaired. The rarefaction or rarity of the air with which its lightness or diminution of pressure is intimately associated has been the subject of many theories; for instance, as causing a starvation of oxygen and the peculiar kind of mountain anæmia, of the existence of which, however, I have not been able to convince myself in the Alps. What seems to be certain is that more blood flows to the surface of the skin, that this organ becomes better nourished, that internal organs become in proportion somewhat unloaded, and, further, that the separation of carbonic acid from the blood in the lungs is facilitated (Marcet and Chermond). I am less certain with regard to the view that a diminished quantity of oxygen contained in a given quantity of air leads to the inspiration of a larger volume of air, and through this to a greater expansion of the lungs and thorax. This theory has been quite lately expounded in a very plausible way by Professor Jaccoud, a great advocate of the curative effect of Alpine climates, in his valuable work on phthisis, of which a good English edition by Dr. Lubbock has just been published. I am not prepared to say that this view is incorrect; but, as I have pointed out already in 1869, and in later communications on the subject, the experiments of Frankland and Tyndall on the burning of candles on the top of Mont Blanc and at Chamounix show that, although the light-giving power of the flame is much less on the top of Mont Blanc, the quantity of stearine consumed, or, in other words, the energy of combustion, is almost precisely the same as at Chamounix. This remarkable result is ascribed by the author of the experiment to the greater mobility of the atoms in the rarefied air, "making atonement for the smallness of their number by the promptness of their action." I can corroborate the experience of Dr. Theodore Williams regarding the increase of the circumference of the thorax, and especially of the diseased side of the chest in several of those cases which have shown a satisfactory progress. I am not, however, sure that this is due to the rarity of the oxygen, as the inhalation of the dry cold air already accounts for it. Whether the thinner air of high regions is unable to hold the microbes floating, and whether in this way rarefaction *is a source* of purity, as Miguel seems to think, I am not able to say; but this point could, I should think, be settled by experiment.

I must deny myself the pleasure of further entering into the details of the peculiarities of mountain air and mountain health resorts. The main physical features important to us are:—1. The purity or aseptic nature; the comparative absence of floating matter. 2. Dryness of the air and soil; comparative absence of mist. 3. The coldness or coolness of *the air temperature* and the great warmth of the sun temperature. 4. The rarefaction and low pressure of the air. 5. The intensity of the light. 6. The stillness of the air in winter. 7. A large amount of ozone. The effects on the invalid suited to such climates are—increase of appetite, improvement of sanguification and general nutrition, strengthening of the heart and circulation, raising of muscular and nervous energy, and of activity of the skin. Under the influence of such constitutional progress, which is assisted by the local action of the aseptic dry and cold air by increased ventilation of the lungs, and by compression of the diseased parts *through healthy* and emphysematous dilatation of the surrounding tissue, we observe a gradual improvement in the state of the lungs, leading to arrest of the disease and actual cure.

(To be concluded.)

THE RADICAL CURE OF VARICOCELE.

BY HENRY LEE, F.R.C.S.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

THE difficulty of performing an operation for the radical cure of varicocele which is at once safe and effective, without any prolonged after-treatment, is evidenced by the number of different proceedings which have of late been advocated. Favourable results have been obtained by most or all of these methods where the veins have been simply enlarged; but in the severer cases, especially when *accompanied* by a relaxed condition of the skin of the scrotum, the benefit derived from the operation has been only temporary.

The operation which I have now been in the habit of performing for some years in such cases is as follows. The surgeon's hands and instruments are washed in a solution of carbolic acid and wiped dry. The patient is placed in a convenient position, generally on the left side of the bed, under the influence of ether. A portion of the skin of the scrotum is then pulled up and removed either by curved scissors or a knife. The longest diameter of the wound should be transverse. The edges of the wound separate to a considerable distance. The enlarged veins are rolled between the finger and thumb, and can easily be distinguished from the vas deferens. Should there be an artery of any size *among* the veins its pulsation can be felt, and in that case it is separated from the veins before the operation is continued. A hare-lip needle is then introduced through the wound under some of the veins, and a figure-of-8 ligature tied round its ends over the veins. The same thing is done with another needle about half an inch distant. A thin knife is then introduced on the flat *beneath the veins, its edge* turned towards the surface, and the veins divided. An ordinary iron cautery, previously heated in the fire, is dabbed on a wet sponge until very little steam is produced; the cautery is then applied to the extremity of the divided veins, and allowed to remain quietly in contact with them for a quarter or half a minute. The tissues adhere firmly to the iron and to each other, and the blood is firmly coagulated in the veins. In order not to disturb the parts by any unnecessary violence, the tissues are gently separated from the cautery by the handle of a scalpel. The needles placed under the veins are now removed and the edges of the wound brought together by short fine hare-lip pins, or by a continuous suture of carbolised catgut. The loss of blood in this operation often does not exceed a teaspoonful. The wound generally heals in great part by first intention. The cautery, applied as described, produces no slough. The charred surface is absorbed, as are also the clots in the veins. At the end of forty-eight hours the patient may be removed to a sofa, and may leave the house within a week.

The son of a medical man had for years been troubled with greatly enlarged veins and a relaxed scrotum, accompanied with occasional pain. He was operated *upon on a* Wednesday, and went down to Brighton on the following Tuesday. An officer in the army, having little time at his command, and wishing particularly to see his friends before rejoining his regiment, had the operation performed and left London within a week. In both these cases the result was most satisfactory. Details of cases might readily be multiplied.

The only inconvenience that has arisen is that in some instances a portion of the wound has been long in healing, but this is accompanied with no pain, and does not prevent the patient going about his usual avocations. It may, however, not be altogether a disadvantage to allow the wound to granulate, as the longer that action continues, the firmer will be the cicatrix. The one danger in operating for varicocele is absorption by the open mouths of the veins. If these are effectually closed a wound in the scrotum may be safely treated in the same way as a wound on any other part of the body, and it requires no very particular attention. When a vein is divided by ligature, or if a red-hot cautery be applied, some amount of ulceration and suppuration necessarily takes place. Both these processes are incompatible with the adhesive action, and the latter can only commence when the former has ceased. If a ligature be applied to a vein, a patient is never safe so long as it is ulcerating its way through; and the same may be said when a portion of the vein is made to slough by the application of the red-hot iron or by the galvanic cautery. The caution that surgeons have always shown in dealing with veins affords abundant evidence of the risks incurred if the veins be not completely closed. This object is effectually accomplished by the application of the actual cautery as above described. The parts are glued together before the operation is completed, a chemical adhesion of the different tissues takes place, the blood in the veins is firmly coagulated, and the vessels are securely sealed.

The removal of a portion of the skin in front of the scrotum as a remedy for varicocele was first, I believe, practised by Dieffenbach, and was advocated by the late Mr. Briggs. In an able memoir published by Dr. Henry, Surgeon to the New York Dispensary, he gives the credit to Sir Astley Cooper of having originally suggested the operation of "amputation of redundant scrotum in the treatment of varicocele." While this operation, he says, had met with much favour and been attended by successful results in New York, it has been comparatively neglected in England, Germany, and France.[1] Mr. Wormald proposed to lessen the scrotal bag by drawing a portion of it through a ring which was worn during the daytime. This is a plan of treatment not uncommon in the present day. The persistency with which patients affected with varicocele occasionally wear these rings and different kinds of suspensory bandages indicates conclusively the relief which they sometimes afford. As long, however, as the veins are left in a varicose condition, the disease cannot be cured. The practice soon, therefore, came into use of obliterating the veins by ligature, and later still by subcutaneous section. A large proportion of the cases in which the last-named operation has been performed have been permanently cured, some have been relieved, and in some the varicocele has become as troublesome as before.

The cases which have been the least successful are those in which the skin of the scrotum has lost its natural elasticity and become relaxed and redundant. The difficulty of dealing with such cases first suggested to me the plan of combining the operation of dividing the veins with that of removing a portion of the skin of the scrotum. This operation may be modified to suit individual cases, but in principle it is that which I am now in the habit of performing. The use of an anæsthetic entirely removes any objections that might be made to the use of the actual cautery on account of any pain which it might be supposed to produce in these operations. Patients sometimes, but very seldom, complain of some burning pain afterwards, but they certainly do not complain more than when the veins are subcutaneously divided. It is well that the bleeding should be completely controlled by pressure before the cautery is applied, otherwise the blood prevents the cautery from remaining fairly in contact with the orifices of the vessels. This may be the case if the iron be heated above the boiling-point of water. There is then a danger of the blood instead of coagulating being boiled, and also of the surrounding tissues being destroyed, instead of adhering to each other. The great advantage of operating with the actual cautery is that the divided vessels are completely sealed, and if the operation be properly performed no bleeding occurs, and no coagula are left in the wound. But that which is of far greater importance is that no absorption can take place through the veins. This is, in fact, the object of all antiseptic dressings. As far as any constitutional effects are concerned, lymphatic absorption is, I believe, unknown as a consequence of the operation above described.

The late Sir James Simpson was in the habit of relating how, after the American War, when he entertained some of the Northern surgeons at dinner, he told them that he believed that they had been in the habit of poisoning the wounds of the Southern soldiers who fell into their hands. The medical officers laughed at the idea; Sir James persisted, and the officers became angry. At length he explained to them that the pieces of flesh, including the divided extremities of the arteries, which were strangulated by ligatures died, decomposed, and were apt to poison the wounds. It is these decomposing particles which have necessitated the various forms of antiseptic dressing which have of late been so profusely used. But if the veins be closed, no such absorption can take place. In surgical operations where the veins can be completely sealed, as in cases of varicocele, venous absorption may be prevented with the greatest certainty.

Many years ago a patient presented himself at St. George's Hospital in whom the scrotum was so relaxed that when he lay upon his back the testes would hang over on the outer side of the left thigh. There was a well-marked varicocele. It was thought practicable to remove a large portion of the skin of the scrotum, and to obliterate the veins at the same time. Two needles were introduced under the most prominent veins far apart. Over the ends of each needle a figure-of-8 ligature was passed, so as to command any bleeding from the veins. The intermediate portion of skin, together with the subjacent tissues containing the enlarged veins, was then removed, leaving a very considerable gap. No hæmorrhage occurred. The needles were then drawn towards each other and the edges of the wound held in position. The wound readily healed and the testis was subsequently retained very nearly in its natural position. This was the first case in which this operation was performed. Previous to that time no one thought of cutting deeper than the skin, as no means were then in use which would effectually control hæmorrhage from the spermatic veins. In the operation which I now perform the portion of skin to be removed is dealt with first, and the veins divided afterwards. The veins are sealed so as to prevent hæmorrhage on the one hand and absorption on the other, and the needles at once removed.

In cases of varicocele where the scrotum is not relaxed, the subcutaneous division of the veins answers very well without the removal of any skin. It was originally proposed to allow the needles which compressed the veins to remain undisturbed for forty-eight hours. It has since been suggested that they might be removed at an earlier period. As far as any fear of hæmorrhage is concerned, this might certainly be done; but, on the other hand, there might be a danger of the circulation through the veins being restored before their divided extremities were consolidated. In the severer cases in which the scrotum has become unnaturally pendulous, it is advisable to remove more skin than at first might appear necessary, so that that which is left may act the part of a suspensory bandage.

Savile-row, W.

WHAT IS THE EXPLANATION OF ACQUIRED IMMUNITY FROM INFECTIOUS DISEASES?

By GEORGE M. STERNBERG, M.D.,

MAJOR AND SURGEON, U.S.A.

(Concluded from p. 657.)

That full justice may be done to the "antidote theory," I quote fully from the latest authority who has written in its favour. Klein says: "There is another theory commonly spoken of as the 'antidote theory' (Klebs). According to this, the organisms growing and multiplying in the body during a first attack produce, directly or indirectly, some substance which acts as a sort of poison against a second immigration of the same organism. I am inclined to think that this theory is in harmony with the facts. There is nothing known from the observations before us which would negative the possibility of the correctness of this theory; nay, I would almost say all our knowledge of the life of the micro-organisms points to the conclusion that the different species are associated with different kinds of chemical processes, and that as a result of the activity we find different chemical substances produced.[1] The different fermentations connected with the different species of fungi afford striking illustrations of this view. According to this theory we can well understand that, just as in the case of an animal, say a pig insusceptible to anthrax, the insusceptibility being due to the presence in the blood and tissues of a particular chemical substance inimical to the growth of the bacillus anthracis—so also in the case of a sheep or ox that has once passed through anthrax—there is now present in the blood and tissues a chemical substance inimical to the growth and multiplication of the bacillus anthracis whereby these animals become possessed of immunity against a second attack of anthrax. Whether this chemical substance has been elaborated directly by the bacilli, or whether it is a result of the chemical processes induced in the body by the bacilli during the first illness, matters not at all; it is only necessary to assume that the blood and tissues of the living animal contain this chemical substance. Some observers (Grawitz, &c.) are not satisfied with this theory, but assume, &c.[2] ...... On the whole, then, we may take it as highly probable that, owing to the presence in the normal blood and tissues of a living animal of a chemical substance inimical to the growth of a particular micro-organism, this animal is insusceptible to the disease dependent on the growth and multiplication of this micro-organism; and, further, that in those infectious maladies in which one attack gives immunity against a second attack of the same kind, one attack produces a chemical substance in the blood and tissues which acts inimically to a new immigration of the same organism; hence the animal becomes insusceptible to a new attack, or is 'protected.' This is not the case with all infectious maladies, for, as is well known, in a good many instances, a single attack does not protect against a second; and, as is also well known, a first attack may protect only for a limited period, or for a period greatly differing in different individuals. All this would be explained by our theory in the same way as it is explained by the other theories—viz., when one attack does not protect, no inhibitory chemical substance has been produced; while in those diseases in which one attack does protect only for a limited period, the necessary inhibitory substance has only lasted for a limited period, and so on."[3]

---

[1] This operation has lately been revived in Paris.

[1] This is beyond dispute.—G. M. S.

It is unnecessary to point out that Klein simply states and reiterates his own opinion in all that he says with reference to the theory which he favours, and that no experimental evidence is adduced in support of this opinion, nor, I may say, any arguments worthy of consideration; yet it would seem that, as in the case of the first hypothesis, a very simple experiment should decide whether this view is tenable. Fortunately, the experimental evidence which shows that it is untenable is at hand, and has been furnished in part by Klein himself.

It is difficult to understand the kind of reasoning which excludes Pasteur's hypothesis upon the ground that the anthrax bacillus multiplies freely in the blood of an immune animal, or in an infusion of the flesh of an animal dead of anthrax, but which supposes that a chemical poison present in the tissues prevents the development of the bacillus in the protected animal. What, then, has become of this poison when the blood of such an immune animal is drawn from its veins into a test-tube, or in the infusion made from the flesh of a recent victim of anthrax? We might possibly admit that the hypothetical chemical substance which remains for years in the blood and tissues of an immune animal, notwithstanding the elaborate provision made by nature for the excretion of useless or injurious products, is dissipated by boiling in the infusion made from the flesh of the animal; but this assumption will not apply to blood freshly drawn from its veins, which also furnishes an admirable culture-medium for the anthrax bacillus. But even this possibility has been disproved by Pasteur, who has given the *coup de grâce* to the antidote hypothesis by the following experiment. He says, "Is this the only possible explanation of the phenomenon?" referring to the exhaustion theory. "No, we may admit the possibility that the development of the microbe, in place of removing or destroying certain matters in the bodies of the fowls, adds, on the contrary, something which is an obstacle to the future development of this microbe. The history of the life of inferior beings authorises such a supposition. The excretions resulting from vital processes may arrest vital processes of the same nature. In certain fermentations we see antiseptic products make their appearance during, and as a result of, the fermentation, which put an end to the active life of the ferments, and arrest the fermentations long before they are completed. In the cultivation of our microbe products may have been formed the presence of which possibly may explain the protection following inoculation. Our artificial cultures permit us to test the truth of this hypothesis. Let us prepare an artificial culture of the microbe, and after having evaporated it *in vacuo*, without heat, let us bring it back to its original volume by means of fresh chicken bouillon. If the extract contains a poison to the life of the microbe, and if this is the cause of its failure to multiply in the filtered liquid, the new liquid should remain sterile. Now this is not the case. We cannot, then, believe that during the life of the parasite certain substances are produced which are capable of arresting its ulterior development."[4]

If Pasteur's experiment, which relates to fowl cholera only, is not considered conclusive, let us consider the tax upon our credulity which this hypothesis involves. In the first place, the individual who has suffered attacks of several different infectious diseases—as for example, of small-pox, measles, scarlet fever, yellow fever, &c.—has stored up in his blood and tissues as many distinct chemical substances as there are diseases in the list, each of which was produced by the development of a specific microbe in his body. These poisons in no way harm the individual, and no one of them, or even the combined action of several, has any effect in preventing the development of other pathogenic microbes of the same class. How different this from the action of known antiseptics, which act in a similar manner, although not in all cases in equal amounts, in restricting the development of all micro-organisms, pathogenic or non-pathogenic, of the class to which known disease germs belong. And how improbable it is that certain substances exist capable of preventing the development of these low organisms in the animal body, which are not injurious to the higher and more sensitive organism, when all our laboratory experiments go to show that the most potent "germicides" and antiseptics are poisonous agents, which are capable of destroying animal life in a relatively smaller proportion than is required for the destruction of "germs." Moreover, we are to believe that these several poisons remain indefinitely in the ever-changing blood and tissues, and that normal physiological processes, by which waste products formed in the cell laboratories of the body are quickly removed from the circulation, are impotent for the excretion of these very peculiar poisons, although non-lethal doses of potent vegetable and mineral poisons are known to be removed from the body in a comparatively short time. We are also required to believe that during the development of a vaccine vesicle in an infant a poison is formed, inimical to the development of the small-pox germ, in such quantity as to afford it protection during the period of its growth and maturity, and perhaps during a long life. In short, the difficulties in the way of accepting this explanation seem to be quite equal to those involved in the "exhaustion theory," and we are obliged to look further for an explanation of the phenomena in question.

As already stated, the explanation which seems to the writer most satisfactory, and most in accordance with the facts, is that which has been denominated the "vital resistance theory." It is well known that living tissues resist the invasion of putrefactive organisms, while dead tissues quickly fall into putrefactive decomposition. So, too, blood within the vessels of a living animal does not behave like the same fluid in a test-tube, but in some way disposes of the bacteria of putrefaction when they are injected into the circulation instead of nourishing them and being decomposed by them. Perhaps the histological elements of the vital fluid which exhibit the greatest vital activity—namely, the leucocytes—may be directly concerned in removing from the circulation bacteria which are introduced experimentally on those pathogenic or harmless organisms which by accident find their way into the blood. However this may be, it is evident that the blood and tissues of a living animal resist putrefaction by virtue of their vitality, and we are justified in using the term "vital resistance" in explaining the immunity of certain animals (acquired), or of certain races (inherited) to the invasion of certain pathogenic micro-organisms belonging to the same class as that which includes the bacteria of putrefaction, although we may not be able to explain the *modus operandi* of this vital resistance or to define exactly what vitality is. We know, at least, that vital phenomena are exhibited by a special kind of matter called protoplasm, and that the living portion of the histological elements of the blood and tissues is composed of the complex nitrogenous substance which has received this name. We know, too, that this living matter, although apparently the same in its gross chemical and physical structure wherever found, has the most varied vital characters, which have been transmitted to it by living matter of the same kind from which it is derived. The special vital characteristics of each bit of protoplasm, enclosed in a cell wall or otherwise, are manifested during its growth, and, as is well known, certain cells—as, for example, the fertilised ovum of a mammal—develop into most complex organic structures; while others, as in the case of a micrococcus or a yeast cell, simply produce other cells like themselves. Not only are the characters which distinguish one species of animal or plant from another transmitted in this way, but individual characteristics may be transmitted in like manner, especially those of a vital or physiological order—such as a feeble or robust nervous or digestive system, a tendency to long life or to premature decay, vital resistance to morbific influences, &c.

---

[2] Already quoted, see ante.

[3] Op cit., p. 219.

[4] Op. cit.

As examples of inherited physiological peculiarities of the order last mentioned, I may refer to the predisposition in some families to diseases of the nervous system—insanity, epilepsy, and the like,—to the vulnerability of others to tuberculous infection, to the small-pox poison &c., and to the very feeble vitality of many children born of parents whose vigour has been impaired by excesses or disease, and which causes them to fall victims to the first devitalising agent with which they come in contact. On the other hand, we have numerous examples of unusual individual or family resisting power to specific morbific agents, and this is still more marked in certain well-defined varieties or races of man and of the lower animals. Thus, the negro, as already mentioned, is less subject than the white man to severe forms of malarial fever and to yellow fever; the Algerian sheep has an exceptional immunity from anthrax; the fatal form of septicæmia in the mouse, which Koch has so well studied, affects only house mice, while field mice are not susceptible to it. But, in addition to these inherited differences in vital resistance to various morbific agents, it is well known to physicians that wide differences in susceptibility to the action of these agents result from influences which lower the individual standard of vitality, temporarily or permanently. Among the most prominent of these influences may be mentioned hæmorrhage, chronic wasting diseases, excessive fatigue, inanition, venereal or bacchanalian excesses, &c. This is shown in a striking manner during the epidemic prevalence of pestilential diseases, which find their victims especially among those whose vital resistance is "below par" from one of the causes above mentioned.

The absolute immunity which certain species of animals have against the infectious diseases of other species is probably due in great part to causes of a different order, and is to be attributed to constant (specific) differences in the chemical composition of the tissues and fluids, and to differences in the normal temperature of the body, &c., which constitute favourable or unfavourable conditions for the development of particular pathogenic organisms. But this is quite a different matter from the relative immunity which results from a single attack of one of the infectious diseases, which may in certain cases be overcome by unusually large doses of the disease poison, by exposure when the general health of the individual is at a low standard—deficient vital resistance of a temporary nature,—or by an unusual individual susceptibility—"idiosyncrasy." There can be no doubt, then, that differences in vital resisting power do exist which determine the development or otherwise of a first attack after exposure to infection in those diseases in which one attack is to a greater or less extent protective; but this does not explain the immunity which follows such an attack. This I believe to be due to an increased vital resistance to the specific disease poison—probably not to the germ, but to the chemical products evolved as a result of its vital activity, and which give it pathogenic power—resulting from a tolerance to this poison acquired during the attack, when it must be present in the system in considerable quantity.

We have numerous examples of acquired tolerance to the action of known toxic agents, and especially to those which *act chiefly upon the nervous system—e.g.*, opium, tobacco, arsenic. And there is evidence that disease poisons produce the morbid phenomena which characterise the acute infectious diseases, in part at least, by their action upon the nervous system. The febrile phenomena, for example, are no doubt largely due to the action of some toxic agent upon the nervous system; and the chemical explanation of fever, which supposes that it corresponds with the rise in temperature observed in a liquid undergoing fermentation, is as crude as is the chemical explanation of immunity. Evidently, if the explanation is correct thus far, the vital resistance of which I speak is a property of the living matter or protoplasm of the body, and resides in the cellular elements of the tissues—nerve cells, gland cells, muscle cells, leucocytes, &c. Now, these cells are not fixtures like bricks in a house, but are constantly being replaced by other cells. Their progeny, which in their turn grow old, die, and give way to younger generations. It is therefore necessary to suppose, in order that this explanation may cover the fact of a continued immunity for many years, that the tolerance acquired during an attack by the cellular elements of the body is transmitted to their cellular progeny through successive generations. This supposition will not overtax the credulity of biologists and of physiologists, for they are familiar with the wonderful power which protoplasm has of transmitting its peculiar vital properties, inherited or acquired, to its offshoots.

The vegetable kingdom furnishes us excellent examples of the transmission of acquired properties through successive generations of cells. Cultivated varieties of fruits and flowers are propagated by slips, buds, or grafts. The cellular elements of each bud or graft are in this case the direct progeny of those in the first cutting, which was selected because of some peculiarity which it was desired to propagate. But if we plant the seed produced by such a bud or slip, we do not obtain the peculiarities of fruit, flower, or foliage which we had preserved by the first mentioned method. In like manner acquired immunity from infectious diseases and acquired physiological or structural peculiarities generally are not transmitted through the reproductive elements of an individual to his offspring, at least not to an extent at all comparable with the transmission of race or family peculiarities. How, then, are these race or family peculiarities established? Darwin has answered this question in a most satisfactory manner for plants and animals in a state of nature. There are congenital differences in the progeny of the same parents which give character to the individual and which are to a greater or less extent transmitted to his offspring. "The survival of the fittest" has a constant tendency to perpetuate advantageous peculiarities, and these are intensified in succeeding generations by the action of the same general law of natural selection. It is by the action of this law that we explain acquired race immunity, as, for example, the superior tolerance of the negro to the action of malaria. Living in an intensely malarious region, a race tolerance has been established for this poison by natural selection and the survival of the least susceptible individuals. In this case we cannot explain the superior tolerance to the malarial poison by supposing that acquired individual tolerance has been transmitted and has become a race character, for the malarial poison is peculiar in that one attack not only does not protect, but constitutes a predisposition to subsequent attacks. I am disposed to explain in a similar manner the marked difference in susceptibility to infectious forms of septicæmia, which is exhibited by carnivorous and herbivorous animals. The herbivora are especially susceptible to these septic germ diseases, which are propogated by inoculation and are known to us mainly by laboratory experiments. It is evident that in a state of nature they are little liable to accidental inoculation with septic material containing the various organisms associated with putrefactive decomposition, and consequently there has been no opportunity for the establishment of race immunity by the survival of the least susceptible. The carnivora, on the other hand, are frequently forced, in a state of nature, to feed upon putrefying animal bodies, and in their battles over such prey must constantly wound each other with teeth or claws smeared with material containing septic organisms. If wolves were as susceptible as rabbits to the forms of septicæmia referred to, it would appear that the species could not long escape destruction. But this is not the case, and I can scarcely doubt that their immunity is the result of the survival of the least susceptible through successive generations; or, in other words, is due to natural selection.

MR. LEWIS W. STEVENS, L.R.C.P. Ed., &c., has been appointed a Justice of the Peace for the district of Robertson, Cape of Good Hope.

ON SOME
SURGICAL ASPECTS OF RENAL TUBERCULOSIS.

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

TUBERCULAR disease of the urinary organs has recently received considerable attention, and the literature of the subject has been importantly added to by the French school of pathologists. In reviewing urinary tuberculosis it is impossible entirely to dissociate any one part of the system as belonging to the physician, it being now well recognised that certain morbid conditions feign well-marked surgical complaints, and give rise to consequences which are only amenable to surgical interference. The observations I am about to make have been led up to by cases presenting symptom indicating the necessity to explore for calculi or to practise cystotomy for their relief.

Tubercle of the kidney in its earliest form I have frequently found to be a cause of incontinence and urinary irritability in children; many children, especially males, who were suspected of stone, proved to have tubercular kidneys. It is not easy always to determine cases of this kind. In one instance recently under observation, where in addition to medical treatment, circumcision of an elongated prepuce had been performed, extensive renal tuberculosis with almost entire atrophy of one kidney was shown after death to have taken place. In assisting to make a diagnosis between what we may call medical and surgical incontinence, I have found the use of the thermometer extremely valuable in doubtful cases. If there are tubercles in the kidney, the temperature will generally show them, provided the observations are continued for some time, in addition to other indications which it is not my province to enter upon.

Of the various operations employed for the relief of urinary affections it would be difficult to mention one that had given better results generally than cystotomy; the least favourable cases, in my experience, have been those where this operation was undertaken for symptoms traceable to tuberculosis. Of these I might instance several. The following example was a particularly interesting and an instructive one of its kind.

Some years ago a small boy four years of age came under my care at the Royal Infirmary, at the request of Dr. Little, on the suspicion that he had a stone concealed somewhere in his urinary organs. He had many of the symptoms of this complaint, but though he had been sounded several times no calculus could be felt. He was the child of distinctly strumous parents, and was singularly bright and intelligent for his age. Twelve months previously he commenced to wet his bed at night and to suffer from urinary irritability in the daytime. Occasionally very small quantities of blood had been detected with the microscope in the urine, which was invariably acid and opaque. Within two months prior to his admission the urine had been charged with mucus and granular matter containing a few pus cells of a tenacious character, efforts to expel which from his bladder produced much spasm and suffering. To aid micturition, and at the same time with the view of mitigating his spasm, he acquired the habit, which at last became constant, of pulling at his penis. He seemed, as it were, to milk away the urine and what it contained from his bladder. It was under these circumstances he came into the infirmary, when it was found necessary to give him sedatives freely. The urine, always granular-looking and opaque, now and then contained something which seemed more like the white of an egg half boiled than anything else. He was sounded, under ether, but nothing abnormal could be detected by any form of physical examination that was employed. Towards evening he was generally noted to have a rise in temperature, and there was a distinct tendency towards hectic. To alleviate the constant pain and spasm of micturition a median cystotomy was performed, but with little benefit. The spasm and vesical tenesmus still continued almost unabated. In the course of a month the child died with renal symptoms and a gradual suppression of urine. Post-mortem examination showed nothing wrong with the bladder or the urethra. The ureters were dilated and the kidneys cystic and tubercular. Some of the cysts thus formed, communicating with the pelvis of the kidney, contained thick gummy-looking mucus similar to that which was observed in a more diluted form in the urine; the cyst walls seemed to be engaged in secreting this viscid matter, which obviously with some difficulty had found its way along with the urine down the ureters. This was the explanation of the dilated ureters, the bladder spasms, and the irritability which led to cystotomy being practised. Without such an explanation it was difficult to understand how the ureters could be dilated, and yet no stricture exist in the urethra.

This case has since served to illustrate, in connexion with others of the kind not very dissimilar in history, progress, and results, at least three points: (1) That urinary incontinence or irritability in young children may proceed from renal tuberculosis; (2) that though cystotomy gives relief by allowing escape of the viscid mucoid material the tubercular cysts in the kidneys furnish when it has reached the bladder by slowly trickling, or insinuating itself down the ureters, there might in other cases of this kind be more cogent reasons for opening and directly draining the cystic kidneys, with the view of preserving what remains sound in structure as well as of preventing the constant spasm or colic which is aroused by the products of the disorganised kidney forcing a way along the ureters; (3) that such a case serves to illustrate those extremely rare cases (of which but few specimens are known to exist) where stones in the bladder have been found, wrapped up as it were in fibrous or gelatinous envelopes.

It was only comparatively recently, until I had by the kindness of Mr. Bickersteth an opportunity of carefully preserving and examining a well-marked specimen of what these tubercular cysts in the kidneys are capable of pouring along the ureters into the bladder, that I felt it possible to explain the formation of semi-fibrous stones. The best specimen I know of is in the Liverpool Infirmary Museum, and has been there referred to by me on a previous occasion.[1] "In 1873 a boy was admitted into the Liverpool Royal Infirmary, under the late Mr. Long, suffering from symptoms of stone. The child was sounded carefully, but without any evidence of stone being afforded. Death occurred in the course of a few days. On making a post-mortem examination the kidneys were found in an advanced stage of tubercular disorganisation and cystic. The bladder was small, and in it lay a calculus made up of a urate of ammonia nucleus, the size of a damson-stone, surrounded by a thick layer of soft material, consisting of mucus, fibrin, and a little gritty matter, probably phosphatic. The outer covering could be cut or torn easily, and after it had been in spirit it presented on section a laminated appearance, like the fibrinous layers found in an aneurysm. On striking the mass with a metal instrument no ring was produced; hence the impossibility of determining its existence with the sound during life." Mr. Bickersteth records a similar example.[2]

The possibility that in a strumous subject a small stone in the bladder may, as it were, be wrapped up in a fibrous sort of coat furnished by a tubercular kidney must not be lost sight of in the investigation of obscure cases of vesical stone, whether or not the explanation I have offered as to their formation be a satisfactory one.

In the diagnosis of urinary tuberculosis in the adult male, in whom this disease is frequently found between the ages of twenty and forty, the careful examination of the testes and prostate with the finger often furnishes valuable evidence as to the probability of tubercle existing in some other portion of the genito-urinary apparatus which is beyond reach. When such evidence coexists with positive signs of functional urinary irritation in some form or other, further evidence as to the cause of the symptoms is hardly requisite. In all cases where there are grounds for suspicion the testes and prostate should be carefully examined. So far as the testes are concerned, there is nothing to be said in reference to their mode of examination. With the prostate it may be observed that our generally recognised method of examining this gland with the patient on his back or side is a very imperfect one, for whatever purpose, diagnostic or otherwise, it is required. To examine the prostate thoroughly and with the least amount of discomfort both to the patient and the surgeon, the former should be placed with his abdomen over the end of a sofa or on a pillow over the side of a bed, with the legs slightly apart, so that the surgeon may introduce the finger into the rectum with its palmar surface downwards, the patient's abdomen being at the same time pressed backwards and towards the pelvic outlet by the weight of the body on the bed. In this way the most accurate information can be obtained by the finger respecting the size, consistence, and relations of the gland. In urinary tuberculosis in the adult male small rounded bodies like shots, sometimes softened in their centres, can be felt either singly or scattered throughout the gland. This I have often demonstrated in the wards of the Royal Infirmary in connexion with the diagnosis of urinary tuberculosis. In young male children, or in adults where the prostate is immature, and it is difficult to make out accurately with the finger, even under an anæsthetic, the consistence and boundaries of the glands, I generally examine with a slightly flattened smooth staff in the bladder; this furnishes a central point of resistance which renders it easy to detect any structural change by the finger, such as a tubercular deposit. I attach much importance to the examination of the prostate in all cases of suspected tubercular disease of the urinary organs.

A CONTRIBUTION TO THE

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.[1]

By GEORGE OLIVER, M.D. Lond.

No. I.—Ten Tests for the Bile Salts, with Demonstration.

The study of the urinary aspect of diseases of the liver is so large, and withal so full of clinical interest, that he who has mastered it merely in outline, cannot well do it justice without devoting a series of papers to the elucidation of it. I, therefore, cannot hope to do more on this occasion and at our next meeting than to provide a sketch of one department—namely, the clinical significance of the colourless central components of the bile in the urine. In this communication I will confine myself to a consideration of the tests which enable us to detect the presence of the biliary salts in the urine, leaving over for the next meeting an outline of the physiological and clinical aspects of the subject.

The urinary derivatives of the biliary salts.—The salts of the bile acids, as they exist in the bile, are taurocholate and glycocholate of sodium, the former greatly predominating. These biliary constituents are not altogether eliminated by the kidneys in the chemical forms in which they are secreted by the liver. When they reach the intestines, they are split up into taurin and glycin on the one hand, and cholate of sodium on the other. The cholate is mainly reabsorbed by the bowels, a small portion only being excreted in the fæces; while the rest is returned to the liver by the portal blood, and is, at least, in part, eventually discharged in the urine. The bile salts, as they appear in the urine, therefore, in all probability, consist of the liver-secreted salts—taurocholate and glycocholate, and of the derived salt—cholate.

The clinical tests hitherto employed for detecting bile salts in the urine are unsatisfactory.—All the works on physiology and on urine refer to Pettenkofer's test—sulphuric acid and cane sugar—or some modification of it, as the only clinical means by which bile acids are to be detected in the urine. However satisfactory this test may have proved itself in the hands of chemists, who have applied it to solutions of the bile acids extracted from the urine, it cannot, I am fully persuaded, claim an analogous position as a mode of direct testing, such as the practitioner requires, for my experience of it as a clinical test has been most disappointing. In delicacy it falls very far short of the clinical needs of the practitioner, and in reacting with other substances besides the bile derivatives—e.g., albumen[2] and other organic bodies—it is apt to mislead the observer. I can, therefore, endorse Dr. Tyson's remarks on this point: "From a perusal of almost all the text-books on Physiology, and even of numerous manuals on the examination of the urine, the student is led to suppose that the detection of bile acids, if present in the urine, by means of what is called Pettenkofer's test, is one of the easiest possible. On the other hand, nothing is farther from the truth, and the fact is that *such detection by the direct application of the elements of Pettenkofer's test to urine, or any other animal fluid, is practically impossible, even if the bile acids are present in considerable amount.* Nor have any of the modifications of Pettenkofer's test, recently announced as clinically available, proved such in my hands, even where the elements of bile have been added to the urine, except where inspissated ox-bile has been used." The italics are Dr. Tyson's.[3] I am disposed to conclude from my observations that Pettenkofer's test does not react directly with the liver-secreted salts, taurocholate and glycocholate, but only so with the derived salt, cholate. Hence, it does not indicate the presence of the biliary salts in fresh ox-bile until it has had time to decompose them, and thus to liberate cholic acid; but it reacts at once, and very decisively, after the bile has been boiled for several hours with caustic potash, a procedure that breaks up the liver-secreted salts, and furnishes the derivate, cholate. This is doubtless the reason why Pettenkofer's test reacts with inspissated, though it fails to do so with fresh bile, for the taurocholate is readily decomposed by boiling only, and the extract is an evaporation product; and, furthermore, why it rarely affords at once a distinctive reaction in jaundiced urines, which are highly charged with liver-secreted salts.[4] The test for peptones, recently introduced by Dr. Randolph, of Philadelphia,[5] may likewise be employed for the direct testing of bile salts, and for this purpose it is delicate; but is unfortunately open to the objection that it reacts equally well with the merest trace of peptone—a constituent often present in small quantity in the urine of hepatic cases, and, moreover, generally in such traces as to be detected with difficulty, and, therefore, cannot always be definitely excluded.

The proposed test is founded on a physiological reaction.—The test I employ for the direct detection of the bile salts in the urine is a purely physiological one, for it is based on a reaction which belongs to the bile itself as it flows into the intestines. When the products of gastric digestion—peptone and parapeptone—which leave the stomach in a state of acid solution, meet with the bile, they are precipitated, as a tenacious layer, all over the villi of the lining membrane of the duodenum.

A solution of the bile salts precipitates acidulated albuminous urine or urine charged with peptone.—The same physiological fact is illustrated outside the body, by acidulating—by means of citric or acetic acid—albuminous urine,[6] or urine charged with peptone, and treating it with a solution of the bile salts, or by ox-bile freed from pigment, mucin, and fat, when the proteid is precipitated. I take a sample of albuminous urine, acidulate it with a citric test paper, and add a few drops of a solution of the biliary salts, and a voluminous white precipitate is observed, just as if I had thrown down the albumen by ferrocyanide of potassium, or by potassio-mercuric iodide. But though like other precipitates of albumen in failing to dissolve when heated, when the bile salts have not been added in excess, it differs from them in this—in vanishing on the addition of acetic acid. This precipitation of albuminous matter from an acid solution is induced not only by the bile salts, taurocholate, and glycocholate, but also by their derivative, cholate of sodium.[7]

---

[1] Read before the Leeds and West Riding Medico-Chirurgical Society, April 10th, 1885.

[2] I have sometimes been led to believe that the presence of albumen retards or prevents the reaction with bile acids.

[3] Practical Examination of Urine, p. 91.

[4] Just lately I met with an instructive instance of this fact in a specimen of colourless bile extracted by aspiration from the gall-bladder of a jaundiced patient. I first of all determined the presence of a *fairly* large quantity of bile salts. Pettenkofer's test, however, afforded no reaction within several hours; but, after boiling a portion of the colourless fluid with liquor potassæ, the test afforded the characteristic colour change in a few minutes.

[5] The Lancet, June 28th, 1884.

[6] Physiological writers assert that the bile only precipitates the proteid from the acid solution that enters the duodenum when in the form of peptone and parapeptone, and not when in that of albumen—as when albumen is dissolved by an acid. If this be so in the duodenum, it certainly is not so in the urine. When a solution of bile salts is added to an acidified albuminous urine, the proteid is precipitated, just as in the case of acidulated normal urine artificially charged with peptone.

[7] Observation shows there are three conditions that prevent the reaction between the bile salts and an acidified solution of albumen

Why not employ an acidulated solution of a proteid in order to detect the presence of bile salts, or the derivative of them, in the urine?—Hence, as this reaction is a thorough-going and decisive one, why not utilise it as a means of discovering the colourless bile derivatives that may overflow into the urine? For if these biliary constituents are present, in however small a quantity, they will surely precipitate an acidified solution of a proteid—resembling, in fact, the chyme—when brought into contact with the urine. Experiment and clinical observation have proved such to be the fact.

Acidification is a necessary condition of the reaction.—I add a solution of the bile salts to albuminous urine, and the mixture is seen to be clear,[8] but on letting fall a few drops of acetic acid into it, the albumen at once falls out of solution, and on the further addition of the acid the precipitate dissolves. Then, again, I take equal parts of an albuminous and of a jaundiced urine, and the transparency of the mixed urines is unaffected; but on dropping in a citric test-paper, a cloud of precipitated albumen collects below, with, however, this peculiarity—the coagulated albumen forms a zone just above the bottom of the tube, where, indeed, the urine remains clear, because the large amount of acid concentrated at this part prevents the precipitate from appearing there. In this case the bile salts present in the jaundiced urine precipitate the albumen, as in the preceding observation, the citric acid merely performing the same duty as when employed in the mercuric or ferrocyanic test for albumen. About twelve months ago I encountered a fact in urine-testing which at that time I could not explain, nor could I derive light either from books or from my friends: the same patient, on different days, provided me with various samples of albuminous urine, which were divisible by the action of citric or acetic acid into two classes—one set precipitating freely with the acid, the precipitate insoluble with heat, and the filtrate albumen-free; and the other set unaffected by the vegetable acid. I carbolised a good example of each kind, and set it aside, believing that the explanation would be forthcoming some day or other. On now re-examining these specimens, I find the one that precipitates albumen by the organic acid contains a large quantity of bile salts; while the other has none—or merely a little more than the trace that belongs to normal urine.[9] The precipitant of the albumen was therefore in this case also the bile salts, which remained inoperative until the vegetable acid was added.

I have lately met with several urines of normal reaction, containing albumen and bile salts, in which the proteid was precipitated by merely adding an organic acid. I show you two examples. This dark urine is a jaundiced urine containing albumen; you see how freely the proteid falls on merely dropping into it acetic acid. And this is a specimen containing an excess of bile salts, but no biliary pigment, along with albumen; and you will note in the course of a few minutes that a citric test-paper produces the characteristic zone-like precipitate, leaving the lowest part quite clear. When the precipitate induced by the organic acid is collected, washed on the filter, and dissolved in an acid (such as acetic or hydrochloric), the albumen is freely precipitated afresh by nitric acid, by the picric acid solution, and by other precipitants of albumen, so that it is albumen and nothing but albumen.

Acidified albuminous urine is a test for bile salts in the urine.—I run this diluted albuminous urine, acidified by acetic acid, over a jaundiced urine, and along the plane of contact of the urines a sharply defined white band or zone of precipitated albumen will be noted, a reaction which is indeed very striking and decisive.

(*To be continued.*)

REMARKS ON

NINE CASES OF DEATH BY HANGING

(SIX EXECUTIONS AND THREE SUICIDES).

BY R. J. KINKEAD, M.D. DUB.,

LECTURER IN MEDICAL JURISPRUDENCE, QUEEN'S COLLEGE, GALWAY.

(*Concluded from p. 658.*)

As far as instantaneous death and freedom from suffering are concerned, hanging by means of the long drop, with the knot of the rope under the chin, seems effective and humane; but it is not unaccompanied with the danger of decapitation. This actually occurred some years ago in Dublin in the case, I think, of Kilkenny, and was then attributed to the use of an old rope which had lost its elasticity. The ropes used by Marwood were also old and had lost their elasticity, but they were thick, I should say an inch to an inch and a quarter in diameter. That decapitation did not occur was probably due to the thickness of the rope, and more especially to Marwood's long practice, enabling him to judge pretty fairly from a look at the criminal, what length of rope should be given. Yet in one of the cases I witnessed decapitation was almost complete, and it seems marvellous that the small portion of skin by which the head was attached to the body did not give way during the hour the body was left suspended. In another most of the tissues inside the neck were torn through and only the skin left intact, so that there must have been in many cases very narrow escapes from decapitation.

I do not enter on the question or express any opinion as to whether it is expedient or inexpedient, right or wrong, that capital punishment should exist. But surely so long as the penalty of death is exacted it is the bounden duty of the State to see the provision made for executions shall be as perfect as possible, so that they may be rapid, painless, and free from the possibility of mistake. The penalty of death is the heaviest punishment the law can inflict; it is a very terrible one, not alone to the criminal, but to those whose duty compels them to witness it. That any bungling should take place or any delay occur through the inexperience or awkwardness of the executioner, or that through his avarice he should be able to dispense with needful assistance, would be to add great cruelty to the punishment; yet under the present system this is not only likely to occur, but has actually happened. There is no such thing as a public executioner for the kingdom. The sheriffs of Middlesex and London appoint one, but his appointment confers no right outside their jurisdiction. The sheriffs of other counties are not obliged to employ him, and there is no fixed scale of pay. It is simply a matter of bargaining, and a sheriff can employ anyone willing to undertake the duty, and pay whatever sum may be agreed upon. Strange as it may seem, there is no lack of competitors for the loathsome office, and there is no guarantee that a totally unfit and inexperienced person may not be selected, and wretched criminals' sufferings prolonged. It seems incredible an execution should be a matter of bargaining, to be touted for like any other trade, yet so it is. I have myself seen a letter from Marwood asking for a certificate as it would be useful to him in his business. So long as capital punishment exists there ought to be a public executioner, with properly trained assistants, a fixed scale of pay, and the sheriffs ought to be obliged to employ them and no others. Furthermore, when more than one person is to be hanged at the same time, it ought to be rendered imperative that the executioner should have a sufficient number of assistants to avoid delay. The conclusions arrived at by Dr. Haughton, in a paper read before the Surgical Society of Dublin, are in the main correct, except that the fall of ten to fourteen feet is too long. In no case I have seen was the drop more than eight or nine feet, yet in one the head was almost severed from the body.

The three cases of suicidal hanging I have to record

---

or peptone—namely, (*a*) an insufficiency of acid, (*b*) an excess of acid, and (*c*) the proteid present in large quantity. The precipitate with an acidified solution of albumen or peptone, or with acidified urine containing either form of proteid, dissolves on adding acetic acid, or a citric acid test-paper, to sixty minims where the bile salts are present below a certain proportion. These facts appear to me to be interesting in connexion with the temporary albuminuria or peptonuria which is confined to the digestive periods, and with the increased elimination of albumen in chronic renal disease which takes place after meals. May not a subacid or a per-acid chyme, or an excess of the ingested proteid, when the bile flow is imperfect, prevent the biliary salts from precipitating—or, rather, from completely precipitating as in health—the albuminoid materials which flow into the duodenum, and thus permit the premature absorption of them?

[8] When the bile salt solution is run upon an albuminous urine, or more especially upon a normal urine charged with peptone, but in neither case acidulated, a delicate zone of precipitated proteid appears, which, however, vanishes on mixing up the solution with the subjacent urine; but the opacity is restored by a citric test-paper, or by a drop of acetic acid.

[9] This patient also on several occasions furnished me with specimens containing peptones in the place of most of the albumen. One of these I also carbolised. On retesting it, I find the peptones still present, with a trace of albumen; and on running over it a diluted solution of acetic acid, there instantly appears a beautiful thick pearly-white zone. Bile salts are present in large quantity.

present some features of interest. In none of them were there any traces of insanity, nor was there anything in their manner or conduct which could have led one to suppose that suicide would be attempted. In only one could any reason for the act be traced.

E. S——, aged thirty-six, was last seen alive at about 1 P.M., when his dinner was served. At 2 P.M. he was found hanging in his cell from the gas-pipe; his feet were about six inches from the floor. The warder who found him cut the body down at once. When I saw him at 2.25 he was quite dead; the body was warm; rigor mortis had not set in. The eyes were half open, pupils moderately dilated. The face was pale and calm. The tongue was not protruded or pushed up against the roof of the mouth, nor was it dark in colour. The fingers were not clenched; surface of body pale; no evacuation of fæces or semen. He had drunk all his soup and eaten part of his bread. He had used his neckerchief as a means of suspension.

T. K——, a strongly built, robust man, aged thirty-seven, was found dead at 6 A.M. hanging by his necktie from his hammock hook. He had been seen last alive at 10 P.M. on the previous evening. When found the body was cold, and he had evidently been dead some time. The body swung clear of the floor, and fæces, evidently passed in the death-struggle, were found on the floor immediately under the body. There was no trace of seminal emission. When I saw the body rigor mortis had commenced in neck and upper extremities. The face was swollen and livid. The right eye closed, the left half open and prominent. The tongue, black, swollen, and protruded, was pressed against the upper jaw; the limbs were livid; the surface of the body was congested and the hands clenched.

T. B——, a lad aged eighteen, had been in prison only a couple of days. He ate his dinner, which was served at 1 P.M. At about 2.10 P.M., after the dinner tins had been removed, he rang his bell and was let out to the closet, where he remained about three minutes and returned to his cell. Ten minutes later the warder, on looking through the trap in the cell door, saw him standing in a curious position against the wall under the window of his cell, which was immediately opposite the door. He at once went into the cell, and found him partially suspended by one of his braces to the chain of his window. He immediately loosened the brace, took the body down and sent for assistance; when found the boy appeared to be quite dead. Professor Lynham, M.D., who lived close to the prison, was sent for at once, and on my arrival at 3 P.M. I found him endeavouring to restore animation, and making use of artificial respiration. All our efforts, however, failed. The face was pale and calm. No prominence of eyes or protrusion or alteration in colour of the tongue, nor escape of saliva from the mouth. Neither was the surface of the body congested, nor were the hands clenched. What was remarkable was the rapidity with which rigor mortis set in: the boy was last seen alive at about 2.20; the body was found partially suspended at 2.30, yet when I saw it at 3 P.M. rigor mortis had commenced in the neck. As, during efforts to restore respiration, the arms were brought down to the sides, the head and neck raised up, and when the arms were extended above the head, the upper portion of the trunk arched slightly backwards—phenomena which rapidly became more marked. The method adopted for self-destruction was peculiar. The cells are heated by hot water, the pipe passing through the cell under the window; the top of the pipe is about six inches from the floor. The window opens on a swivel in the middle, and a slight metal chain attached by one end to the top and the other end to the bottom enabled the occupant of the cell to open or close the window at pleasure. The loop of the chain hung down to the edge of the embrasure of the window, which would be about the level of the boy's neck when standing on the hot-water pipe. The prisoner's braces were made of frieze and lined with coarse calico. The prisoner had stood on the hot-water pipe with his back to wall, passed his brace round his neck and through the loop of the chain of the window; he had not tied it in a hard knot or, I may say, in any knot at all, the ends making merely the first folds of a knot. Whether he then stepped down off the pipe or slipped off will never be known, but when found he was standing on the floor, his back resting against the wall and the brace tightly round his throat. The surfaces of the brace being rough, and the sides of the loop of the chain coming close together under the strain, had prevented the folded ends of the brace yielding, and consequently it held as firmly as a complete knot could have done. Whether the prisoner really intended to commit suicide or only to feign to do so, whether he slipped off the pipe, or that, thinking the fastening would yield sufficiently to allow him to breathe, he stepped off, are conjectures. Taking the entire circumstances into consideration, I believe the intention was to make a feigned attempt, knowing that the result would be his being placed in association in charge of two other prisoners. Experience has shown that when suicide is really attempted care is taken to make secure knots. I am not aware of any case on record in which the ligature round the neck was not tied.

The scientific value of these cases is sadly deficient from the want of post-mortem examinations. The results of suicidal hanging cannot be compared with those of executions, the mode of death being so entirely different; the laceration of the spinal cord, and rupture of the trachea and bloodvessels, preventing engorgement of the lungs and right side of the heart. The appearance, therefore, of criminals after execution cannot be taken as typical of hanging in general. In two of the suicidal cases the appearance was totally dissimilar, although in both the bodies were perfectly suspended. In one, suspension could have only lasted an hour at the outside, probably less; in this case the face was pale. In the other the length of time the body was hanging was uncertain; from the position and size of the hook, and the time taken in making, and the intricacies of, the knots made on the handkerchief, by which it was attached to the hook, it was evident that it was done after daylight had appeared—that is, some time after 2 A.M. The appearance of rigor mortis and the reduction of the temperature of the body led to the presumption that it had been hanging for some hours. The former alone would have been no indication of time; as in the third case, rigor mortis was apparent half an hour after the man had been seen alive. The appearance of the face and body in this case supports the statement that the face is "more often congested, especially in those who have been long suspended."

The third case has more interest in a medico-legal aspect. It confirms the fact, already recorded, that death from hanging takes place very rapidly, even with the feet or other portions of the body resting on the ground. It shows how rapidly rigor mortis may set in and how carefully the mode of hanging ought to be examined, and the means used tested, in all cases where a body is found suspended. Although it is true that in hanging (excluding executions) the presumption is in favour of suicide, yet it may be homicidal, and further, death having been otherwise caused, the body may be suspended after death. If a body had been thus found in any other place with the ligature so incompletely fastened, the presumption would have been in favour of homicide; for *a priori* it would have appeared in the highest degree improbable that a suicide would have been so careless in the arrangement of the noose, or, if he had, it would have seemed unlikely that so incomplete a fastening —only the first fold of a knot passed through the loop—could either have supported the weight of the body, or, without yielding, have borne a strain sufficient to cause death. It would rather have appeared that after death the body had been placed in that position, and that time had failed to complete the knot. Not only was such a supposition entirely out of the question, but I satisfied myself by actual experiment that, with the material used, the arrangement was effectual; for, on placing the brace in the loop of the chain, folded as it was found, and applying a downward strain to the noose thus formed, the sides of the chain came tightly together, which, with the roughness of the material, prevented any yielding and enabled it to bear a weight equal to that of the body. In all three cases the mark of the ligature was distinctly visible on the neck.

Since writing the foregoing two more executions have taken place. In both Berry was the executioner, and his method differs from Marwood's. Although both were single executions, he had the aid of an assistant, who strapped the legs while the executioner adjusted the noose, thus materially shortening the time. Instead of leaving the rope hanging its full length, so that when the noose was adjusted it looped down behind, he coiled the slack of it up under the beam, and fastened the coil with a piece of thread, thus avoiding all possibility of the rope catching under the elbow or foreleg in any way. He also placed the loop under the left ear. In neither case did the coroner consider a post-mortem examination necessary. From an external examination I judged that the vertebræ were separated, but in neither was the separation so marked or distinct as in those executed by Marwood. The faces were deeply congested, the hands were not clenched, and rigor mortis was well marked in both when taken down one hour exactly after the drop fell. My experience leads me to believe that in addition to a proper length of drop, fracture or dislocation of the spinal column and instantaneous death are most likely to be attained by the loop being placed under the chin.

Galway.

THE TREATMENT OF

ACUTE EARACHE BY THE INJECTION OF GLYCERINUM ACIDI CARBOLICI.[1]

BY H. BENDELACK HEWETSON,
OPHTHALMIC AND AURAL SURGEON, GENERAL INFIRMARY, LEEDS.

OF late years the use of various forms in solution of carbolic acid has been so universally prevalent in modern antiseptic surgery that many, as it were, hidden virtues have, by constant familiarity with the drug, become patent, as well as that the cautionary mirages which naturally always arise on the introduction of a new drug have been paled into insignificance before the light of experience. The anæsthetic properties of the drug are now much more fully understood and appreciated than they were some few years ago, although a solution of carbolic acid, short of being caustic, was well known to have local anæsthetic as well as antiseptic properties. Any surgeon who has worked for a long time at an operation such as ovariotomy, for instance, must remember his lack of tactile power when he went to his next meal. I myself have frequently dropped my glass, my tactile corpuscles having become temporarily and locally anæsthetised from constant immersion in the solution of carbolic acid which is used for instruments. In nearly all operations (the removal of a breast, for instance) the glycerinum acidi carbolici is applied to the wound to stop the after-smarting, and this it does effectually. Then arose the application of the glycerinum acidi carbolici to the exposed nerve in toothache. The relief is absolutely instantaneous if the tooth-pulp is exposed, the patient passing from the severest pain to that of a state of bliss, which all testify to who have experienced relief from toothache. I must here, in passing, just allude to the fact that when earache is due to toothache, which it is in a large number of cases, this application of the glycerine and carbolic acid cures the earache by relieving the toothache.

It is now about seven years since a patient came to me saying that his little boy of five years of age had, within the previous three hours, developed acute earache, and that his temperature was above 100° F. The temperature had been taken by his mother, and was rising. The thought occurred to me, why not inject glycerine and carbolic acid into the ears, as it was evidently a case of inflammation of the middle ear, which would eventually end in perforation and relief, as it had in this child done several times before. I injected this solution of carbolic acid and glycerine, and, to my great delight, it acted as in toothache, almost instantly relieving the acute pain. This was done at three in the afternoon, and the next morning the boy was perfectly well, and heard nearly naturally, though not quite, as he still had a cold. The tympanum never became perforated, as it had done on previous occasions, and the temperature rapidly fell to normal. This is a typical case, and I may say that I have repeated it times without number in the same way, both in children and adults—that is, in earache and in catarrhal otitis. In all cases of this kind, at whatever stage it is applied for earache, it invariably stops the pain; and I feel sure that in many cases, even when perforation seemed imminent, the relief from the pain diminished the tension, and by its strong antiphlogistic as well as anæsthetic power perforation has been avoided. If an earache returns, as it does sometimes, where a perforation has taken place and has again closed, the application of the glycerine and carbolic acid gives great relief, and stops the tendency to recurrence to the same thing in some cases, but not in all, although it always relieves pain, and thus constitutional disturbance. In cases of earache from periostitis, either in cases of chronic otorrhœa or in uncomplicated cases of inflammation of the external auditory meatus, the relief to the pain is not so rapid; but if the carbolic acid and glycerine be allowed to remain in the meatus, then relief from pain is obtained in from ten to thirty minutes. It occasionally returns in these cases, when the solution can be reapplied with renewed benefit. By this means I am convinced, by a large experience extending over some years, that if the treatment is used early, perforation of the tympanum can be stayed in many cases. Of course the tendency to catarrh, or other causes which make a patient prone to otitis, is not the object of this paper, nor also is the after-treatment of such cases where the otitis is got rid of. I am dealing only and solely with earache, and the circumstances immediately surrounding it. I may say that I am not only relating my own experience of the treatment; but, in consequence of a paper which I read before the Yorkshire Medical Society, it has been quite generally used by medical men in the north of England who have reported their experience to me. There is one way in which it may fail to relieve pain at once, and that is in case it is poured too quickly into the external auditory meatus, when the patient has his head aside, with the lobe of the ear in its natural position. In this way the air cannot escape sufficiently freely, and a bubble of air prevents the fluid from reaching the bottom of the meatus. The proper way is to draw the lobe of the ear forcibly upwards and backwards, as in syringing the ear, to straighten the entrance to the meatus, and then allow the fluid to trickle gently down one side, whilst the air escapes up the opposite side. In cases where the meatus is very swollen at its orifice, I have injected the solution up a fine elastic catheter well covered with vaseline to promote its easy passage, and in this way I have relieved earache when it could not have been alleviated except by a hypodermic injection of morphia or such means.

I have taken great pains to arrive at the best strength of carbolic acid and glycerine to attain these results, and I find that weaker solutions do not cure the pain so rapidly or effectually. If weaker solutions are used, they will be found to fail in attaining the same results, and of course stronger solutions would soon become caustic. The glycerinum acidi carbolici in this form is not strong enough to be caustic, and can be applied in severe earache when a perforation exists quite harmlessly.

I have a further suggestion to make as to the applicability of this treatment; but I am only able to support my suggestion by a few successful cases which have come under my own observation. I refer to this application as a means of checking the disastrous otitis in scarlet fever, as well as to relieve the earache in these cases. I am very hopeful on this point; for in one or two instances where I had an opportunity of applying the glycerine and carbolic acid, when a patient first complained of earache in scarlet fever, and the membrana tympani had begun to redden, the relief to pain was immediate, and no perforation took place.

I make the suggestion, and hope all who have the opportunity will try it, since one important (very important) element, I take it, to anyone, much more to a patient in high fever, is the immediate relief from local pain, which must act as a beneficent element in assisting the patient through his illness.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this Society was held at 53, Berners Street, on April 8th, Mr. Tegart, V.P., in the chair. Six new members were elected, and the death of one reported. Applications for grants were read from sixty-three widows, nine orphans, and three recipients of grants from the Copeland Fund, and a sum of £1349 was recommended to be distributed among them at the next quarterly court. A fresh application for grants was made by a widow on behalf of herself and daughter, and grants were made them. Mr. Henry Lee and Mr. Cooper Forster were nominated for election as vice-presidents at the annual general meeting, in the place of Mr. Cæsar Hawkins and Sir Erasmus Wilson, both deceased, and the following gentlemen were named as directors to fill the vacancies arising from the retirement of the six senior, and from the death and resignation of others—viz., Mr. Hogg, Dr. Barker, Dr. F. Roberts, Dr. Broadbent, Dr. Ogle, Dr. Duka, Mr. Bennett, Mr. J. S. Turner, Mr. Stokes, and Mr. Latham. The annual general meeting was fixed to be held on May 20th at 5 p.m.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. THOMAS'S HOSPITAL.

A CASE OF LITHOTRITY; REMARKS.

(Under the care of Mr. Clutton.)

The following case of lithotrity with prolonged manipulation is a good example of the method of procedure introduced by Bigelow in the year 1878, which he prefers calling litholapaxy, but which retains the name of lithotrity in this country. In this case the amount of débris produced was such as to render its removal at one sitting impossible, without exposing the patient to unnecessary risk, the remainder being removed seven days later without any inconvenience having resulted to the patient in the meanwhile, whilst the good effect of the first operation was well marked. The stricture, which had been carefully dilated, does not appear to have interfered with the progress of the operation, nor to have caused after-trouble.

R. R——, a coachman, aged forty-nine, was sent to Mr. Clutton by Dr. Phillips of Bromley, Kent, in the autumn of 1884. For eight months he had suffered from frequency of micturition; and during the latter part of this time had begun to feel pain at the end of the penis after emptying his bladder. The frequency in passing urine troubled him as much during the night as in the daytime; so that it is open to question whether this particular symptom was not due to the presence of a stricture from which he had suffered for fourteen or fifteen years. He had of late neglected the stricture, and thought that all the symptoms were due to this neglect. He had during the last three or four months noticed blood occasionally in his urine, which had at the same time become thick and ropy. The pain at the end of the penis and an occasional presence of blood in the urine made it probable that there was also a stone in the bladder. A No. 6 silver catheter was with difficulty passed through a stricture at about four inches from the orifice of the urethra. A small-sized sound was then introduced, and a vesical calculus detected. He was therefore admitted at once into the hospital. In the course of a fortnight the stricture had been so far dilated as to admit a steel sound of the size of No. 30 of the French scale. But the symptoms of irritation in the bladder had been much aggravated. He was passing urine almost every half hour, and had to keep a "slipper" constantly in bed. There was also a large quantity of pus and mucus in the urine that he evacuated. It was determined, therefore, at once to give him relief by lithotrity.

On Oct. 15th, 1884, the patient being brought under the influence of an anæsthetic, a Bigelow's lithotrite was introduced and the stone seized. It proved to be about two inches in diameter, but of soft and crumbling consistence. It was therefore very easily crushed, but the amount of débris produced was so large, and the stone had broken up into so fine a powder, that even at the end of an hour and a half a considerable amount was known to be left behind. The weight of the fragments removed at the operation after careful drying was 659 grains, or a little over an ounce and a half; but no great care was taken to preserve all the fluid that came away, so that a good deal of the fine powder was lost.

On the 17th, two days after the operation, he said that he felt better than he had done for some months. He had no pain except some slight scalding in passing urine, and this was accomplished about once in two hours, instead of every half hour. Altogether the relief was very great. The urine also was quite clear, containing only a few fragments of the crushed calculus.

On the 22nd an anæsthetic was again administered and the bladder washed out by Sir Henry Thompson's improved evacuator and a No. 18 cannula, which had been used at the first operation. The second operation lasted about three-quarters of an hour, and the fragments, dried and weighed, amounted to 336 grains. The bladder was again washed out in the same way on the 30th, but very little débris indeed came away.

The patient left the hospital perfectly well on Nov. 4th. The stone was entirely composed of phosphate, and therefore very light for its size; but when thoroughly dried, the total weight of the fragments removed by the evacuator, with those passed in the intervals, was 1026 grains, or 2 oz. 151 grs. The original calculus must therefore have been of considerable size.

Remarks by Mr. Clutton.—This case is of interest on account of the large size of the stone, the few symptoms to which it gave rise, and the very short time that these symptoms had existed. There was, moreover, a stricture of the urethra, which increased the difficulties of the case.

LIVERPOOL ROYAL INFIRMARY.

CASE OF DISLOCATION OF THE SHOULDER, REDUCED AFTER ABOUT SEVEN WEEKS, AND FOLLOWED BY ANEURYSM (SUBSCAPULAR?), TREATED SUCCESSFULLY BY LIGATURE OF THE SUBCLAVIAN; REMARKS.

(Under the care of Mr. Rushton Parker.)

This case is very interesting as an illustration of a rare accident following the reduction of dislocation of the humerus. The patient was not of an age when one expects degeneration of the vessels, and the dislocation was a comparatively recent one, apparently requiring no excessive force for its reduction. The aneurysm probably followed laceration of the dorsalis scapulæ artery, as suggested by Mr. Parker, and this may possibly have been injured at the point where it turns round the axillary border of the scapula, at which point it would be most exposed to injury during the necessary manipulations.

A woman, aged thirty-six, fell and injured her right upper limb in the first week of December, 1882. To the medical man who attended her she only complained of her forearm, in which he found a fracture, and treated it successfully. Four weeks later, her forearm being nearly well, she went to the Liverpool Royal Infirmary, complaining of her shoulder and general lameness and pain in the limb. On examination the head of the humerus was found dislocated, the limb somewhat œdematous, and the injured forearm satisfactorily healed without deformity. After two attempts at reduction under ether, with the heel in the axilla, by Mr. Harrison's house-surgeon, the case was placed under the care of Mr. Rushton Parker, who is indebted to Mr. Harrison for the opportunity of attending it. Again, under ether, reduction was attempted on Jan. 23rd, 1883. The patient was laid on the operating-table, having a roller towel passed round her chest on the affected side, and looped at the other end to an adjacent iron post, being put on the stretch between. This maintained her fixed while the limb was submitted to linear extension at an angle of about 60° from the trunk. At first the hands of those employed slipped off the œdematous limb, on which another roller towel was hitched on the limb, and steady traction kept up by three or four students, while Mr. Parker directed their movements, clasped the head of the bone, and kept it outwards, while the arm was brought to the side. After prolonged efforts, without any jerking, the bone was found replaced in its proper situation without any indicating sound or perceptible movement at the moment of reduction. The wrist was slung to the neck, with the elbow flexed, and the patient was put to bed. Some ecchymosis resulted and pain in the shoulder, neither more nor less apparently at first than at the previous attempts. But the pain continued; and on viewing the shoulder from time to time to ascertain the cause, there was noticed on Jan. 29th a pulsating swelling over the axillary border of the scapula behind. The pulsation was distensile; the swelling evidently communicated directly with an artery, and its size was about that of a small walnut, with additional induration around. The radial pulse was unaltered on this side, and during the period in which it was examined the position of the aneurysm was more and more conspicuous at the border of or outside the axilla, and near the situation of the dorsal scapular artery or the subscapular at the junction of the two. The swelling under rest in bed did not show any sign of diminution, but rather of increase; it was attended by severe neuralgic pain, that greatly distressed the patient, who could hardly sleep. At a consultation with his surgical colleagues, Mr. Parker's proposal to tie the subclavian artery was agreed to. This was accordingly done on February 16th, 1884, under ether, with Lister's carbolic acid method and a chromicised catgut ligature. After the skin incision and the closure of its vessels, the fasciæ were divided with two pairs of dissecting forceps, the successive apertures being held open by Mr. Harrison with a pair of artery forceps in each hand. The artery was too deep to thread the aneurysm needle after passing it, so the needle had to be withdrawn and passed threaded. Pulsation ceased at once on compressing the artery against the finger with the ligature, so the latter was tied, cut short, and the wound sewn and drained, being covered with a Lister's gauze dressing. Union by first intention resulted without inconvenience or complication. The blood tumour that had pulsated remained for weeks unreduced in size, and felt so soft that Mr. Parker was tempted to aspirate it. This failed, as the blood was clotted, though soft. Eventually a puncture was made on March 10th, under a stream of carbolic lotion, and some black clot squeezed out. Decomposition eventually occurred, but was quickly corrected by carbolised washing, and entire cicatrisation resulted. The patient was kept in hospital all the summer, her arm being slung the whole of the time, and the stiffness of the shoulder gradually becoming slacker. She was lost sight of, and when sought in April, 1884, could nowhere be found.

Remarks by MR. PARKER.—Six weeks after an accident one would hardly expect reduction to be so difficult as in this case. The parts were, no doubt, stiffened by the previous attempts, and all rendered difficult by inflammatory stiffening, which may have resulted from her own neglect of the injury, due to her ignorance of its existence and the omission of remedial precautions. The pulsating blood-tumour was a good example of circumscribed traumatic aneurysm that results from arterial rupture subcutaneously. It certainly did not appear to communicate directly with the axillary trunk, and was thought likely to be subscapular or dorsal scapular both from position and behaviour. Under any circumstances this must be a rare situation for aneurysm, though perhaps more likely to follow a stab than any other predisposing cause.

THE FRENCH HOSPITAL.

DISLOCATION OF THE FOREARM, OF EIGHT WEEKS' STANDING; REDUCTION; REMARKS.

(Under the care of Sir W. MAC CORMAC.)

FOR the following account we are indebted to Mr. Alfred S. Gubb, resident medical officer.

Léon P——, aged twenty-four, a musician, on Dec. 23rd last, was returning home late at night, carrying a parcel in each hand, when he was assaulted and knocked down quite unexpectedly. On rising he found himself unable to use his right arm, and any attempt to move it was attended with much pain. The next day he went to a neighbouring hospital, the arm being then very much swollen, where the case was diagnosed to be one of fracture just above the elbow-joint, and the limb was put up in an external angular splint reaching from the shoulder to the wrist. He returned to the hospital several times subsequently, but the arm was left undisturbed, until, being dissatisfied, he went on Feb. 9th to the French Hospital, where the splints were removed and the limb examined by Sir William Mac Cormac, who found a dislocation of both bones of the forearm backwards and slightly outwards. The patient was put under an anæsthetic and the adhesions broken down by flexion and extension movements, and efforts made to reduce the displacement by these and counter-extension. It was, however, only after three-quarters of an hour of very energetic manipulation that reposition was effected. The limb was then put up in fully flexed position, and secured by a plaster-of-Paris bandage. A good deal of swelling and pain followed, which were subdued by the continuous application of the icebag and the administration of opium. The limb was left in this position for a fortnight, and then passive movements were cautiously resorted to. A good deal of stiffness of the elbow and fingers remained, but after another fortnight of massage and passive movement the patient was enabled to extend the arm about forty-five degrees beyond a right angle, and to use his fingers with some amount of comfort. He left the hospital for Paris with every prospect of a useful limb.

Remarks by SIR WILLIAM MAC CORMAC.—Dislocations of the elbow are rare in adults, and in this case the interval was nearly the limit at which a successful reduction can be accomplished. Further, it serves to illustrate the difficulty of diagnosis in injuries to the elbow when the relations of the part are concealed by swelling.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Aneurysm of Abdominal Aorta treated by Distal Compression.—Localisation of Motor Centres in Spinal Cord.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair.

MR. T. R. LUNN and DR. F. L. BENHAM read a paper on a case of Aneurysm of Abdominal Aorta treated by Distal Compression. The patient, a man aged thirty-two, a shoemaker by trade, was admitted into the Marylebone Infirmary, in October, 1883, with a large abdominal aneurysm. He had been in the army nine years, and had syphilis five years ago. There was no history of strain or injury. The urine contained a slight trace of albumen. The patient was not relieved by the usual remedies, including rest, low diet, narcotics, &c. He was evidently getting worse, and was extremely anxious to have some operation done, the danger attending which was explained to him. On October 31st the patient was placed under the influence of chloroform, and compression of the abdominal aorta just above, and to the left of, the umbilicus was kept up four hours and three-quarters with Carte's tourniquet. There was slight vomiting on the first and third days after the operation (apparently due to the morphia and chloroform combined), but otherwise the patient expressed himself as feeling better; the tumour was smaller, harder, and pulsation less marked. The man continued to do well for seven days, but on Nov. 8th persistent vomiting set in, chiefly of a dark grumous material. The pulse was feeble, 192; there was intense thirst, no abdominal distension or pain, some dulness over right lung, the face was congested, and the feet warm. The patient became worse, and died on November 10th, the eleventh day after the operation. At the autopsy the aneurysm was found to be cured, but there was gangrene of about two feet of the jejunum.

MR. HENRY MORRIS contributed a paper on a case of Gangrene of the Right Lower Extremity, due to an aneurysm which was full of laminated clot, and therefore practically cured. The patient was a man aged thirty-eight, who on December 27th, 1884, suddenly felt, whilst walking, severe pain, numbness, and pricking in the right leg, accompanied by profuse sweating; the left leg was also affected in a less degree, but the mobility and sensibility of the left lower limb returned, though the right remained paralysed and without sensation. On January 1st the patient was admitted into Middlesex Hospital. There was a history of syphilis sixteen years previously. Six months ago he had had lumbago, and later on drowsiness and throbbing of the right temple. On admission there was gangrene of the right lower limb; the femoral artery could not be felt. Some weakness and coldness of the left foot were present. On the right side of the abdominal parietes the veins were greatly distended. It was decided to wait before amputating the gangrenous limb. On January 14th the right limb was amputated through the lower third of the thigh by the circular method; a feeble, tiny stream of blood flowed from the superficial femoral artery. The eighth day after the operation the man died; delirium and diarrhœa had been present, and the urine was albuminous. At the autopsy the intermuscular planes of the stump were infiltrated with badly smelling sanguineous fluid. There was an infarct in the liver, and this organ weighed 71 oz.; the kidneys were swollen, and weighed 7¼ oz. each; in the right kidney there was an infarct. Atheromatous patches were present in the aorta, and an oval aneurysm, full of laminated clot and two inches and a half in length and of the size of a Tangerine orange, was found close to the superior mesenteric artery, which, however, was not involved. The bodies of the first and second lumbar vertebræ were eroded. The blood-clot extended into the aorta. Just above the right profunda artery there was an embolus. The vena cava inferior was completely blocked, as were also the common iliac veins. The case was brought forward chiefly to show that even an aneurysm which had been cured by nature could by accident cause the death of the patient.

Mr. R. Barwell said that it was unfortunate that the paper should have confounded proximal and distal compression for the treatment of abdominal aneurysm. There were now four cases of treatment by distal pressure; in two no benefit and no injury resulted. In Mr. Bryant's case the intestinal injury was the cause of death, just as it was in Mr. Lunn's case. He doubted whether the soft spongy clot occurred as the result of pressure, or as the result of arrest of the circulation during the last moments of life.—Mr. Bryant said that in his case of distal compression he thought he could, with justice, attribute the clot in the aneurysm, not to a recent formation, but to one which had been formed slowly during the compression of the aorta. He considered that Mr. Lunn's case was an encouraging one for the treatment advocated. He asked for further particulars as to the precautions which were taken in applying the tourniquet.—Mr. T. Holmes said it was open to doubt whether the treatment ought to be described as distal pressure; for there was but little space between the terminal portion of the aneurysm and the bifurcation of the aorta; it was more likely that there was direct compression of the aneurysm. He thought that distal compression was not likely to cure the aneurysm, but more likely to kill the patient. There were so many sources of collateral circulation that a cure was almost impossible. The risk of rupture of sac was great. He was inclined to think that in Mr. Lunn's case there was a genuine tendency to the cure of the aneurysm, for it had the appearance of being firmly consolidated; but he thought that this consolidation was not the result of distal pressure on the aorta.—Mr. Hulke concurred with the remarks of Mr. Holmes, and doubted whether the exact seat of the pressure could be definitely asserted, even when it was supposed to be applied proximally. In two out of three cases which had been under his observation there was direct pressure on the aneurysmal sac. The result in all his cases was successful, and the aneurysm was consolidated. Nevertheless, the dangers were great, and considerable risk must be run.—Mr. H. Morris spoke of a valuable contribution to the subject made by Mr. Barwell to "Ashhurst's Encyclopædia of Surgery." There were ten cases in which proximal pressure had been used, with recovery in five cases and death in five cases. Death was due to bruising of the intestine and peritonitis. It was a question as to how far the intestinal injury was due to direct pressure on these structures or to embolism of the superior mesenteric artery. He would like to know what chance there would be of gangrene of the intestines when the superior mesenteric artery was occluded. We had to do with the same dangers whether proximal or distal pressure were employed. He spoke on a subject to which he had already drawn attention—viz., that aneurysms may be cured by nature and yet bring about the death of the patient. His own case proved this, as did also a case of aneurysm of the ascending aorta in which consolidation had taken place; but a minute rent formed, through which leaking into the pericardium took place and caused death.—Mr. *Jonathan Hutchinson* doubted whether medical treatment was wholly powerless to cure cases of abdominal aneurysm situated high up on the aorta. He referred to a case of his reported in "Holmes' System of Surgery," in which the free administration of diacetate of lead to the degree of producing a blue line on the gums and lead colic was carried out, together with the use of ice-bladders over the abdomen, a dry diet, and absolute rest. In this case within three months there was a complete cure, and the man went to work. He agreed with Mr. Holmes that there was a very great risk of causing the death of the patient by the method of distal compression. In ergot of rye, diacetate of lead, and iodide of potassium we had powerful drugs which might be used in combination, and which were able to exert a very important influence on the state of the blood and arterioles.—Mr. J. R. Lunn, in reply, said that before the tourniquet was applied the bowels were thoroughly emptied, and the bladder also. Gradual pressure was made after the skin and tourniquet had been properly dusted with powder. Carte's tourniquet was a very convenient one. The patient was a most restless man and difficult to keep at absolute rest, though this and large doses of iodide of potassium had been attempted for a period of one month without benefit.—Dr. Benham, in reply, quoted some references to prove that embolism of the branches of the superior mesenteric artery could cause gangrene of the intestines. He was of opinion that the pressure of the tourniquet was distal and not immediate.

Dr. C. E. Beevor read a paper on two cases illustrating the Localisation of Motor Centres in the Brachial Enlargement of the Spinal Cord. The first case was one of progressive muscular atrophy, occurring in a goldbeater and lamplighter, aged thirty-eight. The disease commenced three years ago, with gradual wasting and loss of power, beginning in the muscles of the back of the right forearm, the muscles of the hand and the interossei, and involving other muscles of the right arm. The left arm was affected a year later, with difficulty of supinating the forearm, flexing the elbow, and abducting the shoulder-joint. The legs have been weak for the last six months. At present the muscles most affected on the right side are the small muscles of the hand and interossei, the flexors and extensors of the wrist and fingers, the teres major, serratus magnus, deltoid, biceps, brachialis anticus, supinator longus, rhomboid, and teres minor. On the left side the same muscles are affected, except the small muscles of the hand and the flexors of the fingers; while, in addition, the clavicular part of the pectoralis major are slightly affected, and the supra- and infra-spinati are involved. The second case was that of a young man aged eighteen, suffering from infantile paralysis. The onset was sudden when the patient was a year old, with paralysis of all four limbs, of which the legs and right arm have recovered fairly well, while the left arm has remained more paralysed. At present, in the right arm, the only muscles affected are the latissimus dorsi, triceps, and pectoralis major, the sternal part of which is absolutely gone. On the left side, in addition, the teres major, subscapularis, rhomboid, supra- and infra-spinati, and teres minor are severely affected; while the extensors of the fingers, serratus magnus, and deltoid are only slightly involved. There was nothing of great importance in the course of the two cases; but they were brought forward to illustrate clinically the groups of muscles found by Professors Ferrier and Yeo to be thrown into action by faradising the peripheral ends of the divided anterior motor roots forming the brachial plexus. These groupings were shown in some tables, and side by side with them were given the muscles found to be affected in these two cases. On comparing the cases, it will be seen that whereas in the case of progressive muscular atrophy the groups of muscles severely or completely affected belong chiefly to the fourth, fifth, and eighth cervical and first dorsal nerves on the right side, and mainly to the fourth and fifth cervical nerves on the left side, in the case of infantile paralysis the opposite holds good, for on the right side the only muscles affected (the triceps latissimus dorsi and pectoralis major) are innervated, according to Ferrier and Yeo, only by the sixth and seventh cervical nerves, whilst the rest of the groups are unaffected; and on the left side the sixth and seventh cervical nerves are most affected, and also some muscles innervated by the fourth and fifth cervical are partially paralysed. The reaction of the muscles to electricity (faradisation and constant current) has been ascertained, and they correspond to the degree of power lost and to the amount of wasting, and are quite in accordance with the above groupings. A third case of infantile paralysis was also described affecting the muscles of the right arm, corresponding to the sixth and seventh cervical only—viz., teres major, latissimus dorsi, subscapularis, pectoralis major (sternal half), triceps, and serratus magnus. It should be remarked that Ferrier and Yeo's experiments were made on the motor roots, but it is considered that the groups of muscles thereby differentiated can be equally applied to the cells of the anterior cornua supplying these nerves, and these cells are known to be affected in progressive muscular atrophy and infantile paralysis.—Dr. Hughlings Jackson said that Dr. Beevor's observations were an example of a kind of work that was much wanted. Ferrier's experiments gave us some clue to the nature of the mixing up of the nerves at the level of the lowest centres. Lesions of the cervical region of the spinal cord were known to have an influence on the pupil. In these cases the pupil was small and unable to dilate when the eye was shaded. Stabs of one half of the cord illustrated this, as did also cases of rupture of the brachial plexus. Ferrier's experiments were more definite in this regard, for they showed that it was only the second dorsal motor root in the monkey which contained the dilating fibres of the iris. Stimulation of this root causes dilatation of the pupil and contraction of the intrinsic muscles of the hand. In a case of progressive muscular atrophy under his care the intrinsic muscles of the hand were affected, and there was smallness of the pupil on the same side, and inability of the pupil to dilate when the eye was shaded, thereby affording a clinical corroboration of the experimental work. A case of Mr. Rivington's also bore out the same fact.—Dr. **FERRIER** said it was important that his and Yeo's experimental observations had been corroborated and verified by clinical research of so laborious a kind as that which Dr. Beevor had undertaken. The intricate plexiform arrangement of the brachial and crural nerves had long been a physiological puzzle, and his experiments were undertaken with a view to clear up the mystery. He and Yeo had found that each root of the brachial plexus of the monkey answers to a distinct and well-defined muscular action due to coördinate contractions and relaxations of groups of muscles. It was most probable that centres of complex coördination existed in the brachial enlargement of the spinal cord. Stimulation of the cervical nerves going from the upper part of the brachial swelling gives rise to a combined and coördinate movement in which the deltoid, biceps, brachialis anticus, and supinator longus muscles took part, as in the act of raising the hand to the mouth. He referred to some observations in human anatomy made by Dr. Cunningham, which showed that twenty-seven out of thirty-seven subjects examined the second dorsal nerve sent a contribution to the brachial plexus. If this relation were found to hold good, then there would exist a complete harmony between the nervous relations of the brachial plexus in man and monkey. It was important to decide whether the nuclei of all the muscles were present in each segment of the brachial swelling or whether they were arranged in a linear order. In his opinion the facts of anterior poliomyelitis seemed to show that in each segment we have the nuclei of all the muscles. Neurologists had come to recognise an upper arm type and a lower arm type, and he believed that there were as many distinct types as there were groups of muscles. In the middle of the brachial enlargement there was a coördinating centre which presided over the latissimus dorsi and pectoralis major and the rotators of the shoulder-joint. It was highly probable that in the spinal cord there were mechanisms for the carrying out of complex coördinate actions, and he believed his experiments had roughly mapped out the chief of these mechanisms.—Dr. **BEEVOR** said that in one of his cases the right pupil did not dilate when shaded, and so resembled the instance of which Dr. H. Jackson had spoken. In this case the first dorsal nerve supplied the group of affected muscles, and therefore still further corroborated the views of Ferrier.

CLINICAL SOCIETY OF LONDON.

Amputation at the Hip-joint.—Pityriasis Circiné.

AN ordinary meeting of this Society was held on April 10th, Mr. Thomas Bryant, F.R.C.S., President, in the chair. There was a well-sustained discussion on the surgical papers.

Dr. **LEWIS W. MARSHALL** read a paper on Amputation at the Hip-joint by Furneaux Jordan's Method. The author, in giving a record of ten amputations at the hip-joint by this method, mentioned at the outset the fact that a paper had been previously published by him in the *British Medical Journal*, October 27th, 1882, on the same subject. He likewise mentioned that Dr. Maclaren of Carlisle also read a paper in Edinburgh, which was published in the *British Medical Journal*, June 7th, 1884. He gave a brief account of the two methods of operating suggested by Mr. Jordan in THE LANCET, March 23rd, 1879, stating that he himself preferred the second method, which was done by making the circular sweep through the soft parts first, the enucleation of the femur being the second step. Of Dr. Marshall's ten cases, three were done after excision, and the remainder when this operation could not be practised on account of extensive implication of the femur or pelvis, or from the general condition of the patient prohibiting more conservative measures. The ages of the patients were as follows: two at eleven, one at ten, two at eight, two at seven, one at six, one at five, and one at three years. In all but one the fingers were used to compress the femoral artery in the groin. Esmarch's bandage and Davy's lever were spoken of, and had been used, the latter in the only case which has to be recorded as a death in this list. This death occurred within a few hours after operation from shock, the result of loss of blood. The amputation was on the right side. The patients are living and well, with the exception of two. These deaths were due to visceral lesions. The dressing used in each case was a loose antiseptic covering of carbolic oil and lint. Stress was laid upon the after-treament of the patient. Food was withheld by the mouth for some hours, if iced champagne be excepted, nutrient enemata being given instead. An extract was read from Mr. Jordan's paper, detailing the advantages of his method over the older flap operation. The reason given for the choice of the second method of operating was as follows:—"That the increased length of leverage gained by freeing the limb from the main attachment of the muscles enables the fingers and the knife to pare the muscles off from the bone with much less risk of wounding vessels unnecessarily." It was also stated that the separation of the tough bands which in old-standing cases of hip disease weld the trochanter and what exists of the neck of the femur so closely to the pelvis is rendered easier and more rapid. The fact of the gluteal vessels remaining untouched was insisted on. Dr. Marshall also spoke of the possible risk to the patient when disease was present in the pelvis by the use of Davy's lever. The use of this instrument appeared to be undesirable, because the efficacy of the nutrient enemata might be interfered with. Mr. Wright, Senior Surgeon to the General Hospital, Nottingham, controlled the common femoral. The hand in the groin for this purpose was in no way a hindrance to the operator. The femoral artery was always tied after the circular incision was made. The stump left by Jordan's method was said to be all one could wish for. A case in which albumen in the urine had been present for some time, and where the liver was enlarged to the umbilicus, is now living and well. The albumen could be found up to ten months after amputation. In two other cases large deposits of albumen were present when amputation was done.

Mr. **JONATHAN HUTCHINSON** read a paper entitled a Plea for Amputation at the Hip-joint in certain Cases of Advanced Suppurative Disease. The author commenced by stating that he had no new method of treatment to recommend, but simply the more liberal adoption of an old one. He believed that not a few cases of advanced suppurative destruction of the hip-joint would be more safely treated by amputation than by excision or by rest; especially did this remark apply to cases in which the limb was diseased at other parts, and damaged as regards its usefulness. He included also some which after excision were not doing well. In all cases in which such conditions existed, he felt sure that the surgeon would do well to remember that amputation at the joint was usually very successful even in cases of extreme exhaustion. It was also usually followed by rapid restoration to good health. The difference between operations for disease and for tumours was very great. The former were attended by obvious relief from the very first, the latter not unfrequently by severe shock. Bearing this in mind, he felt sure that it was often a mistake in practice when open suppuration was established, and the patient's strength failing, to delay or decline amputation at the hip-joint. In looking back in his own practice he recollected several cases in which he much regretted not have done so. In such the patient was always in danger of the development of lardaceous disease, as well as in risk of his life from hectic or some intercurrent malady. Particularly in adults is the hopefulness of recovery from suppuration of the hip-joint very poor. Several cases were related. In one, in an adult, there was disease of hip and knee together, and in another disease of hip and femur together. Both were in a state of extreme exhaustion, and both recovered well. In another case, in a boy, the operation was done in spite of advanced lardaceous disease and an enormous liver, with the result of greatly improved health and diminution of the liver. In a fourth case, in which extreme exhaustion from suppuration was the reason for amputation, erysipelas had attacked the limb on the day before the operation, yet a successful result ensued. The author stated that he had not in any single case lost a patient as the immediate result of the operation, nor was he aware that anyone had subsequently died. Respecting two, however, he was obliged to report that they had not regained good health nor had their sinuses healed when last seen. As regards the mode of operation, it had varied with the nature of the case. Of late he had used Furneaux Jordan's method, of which he thought highly. In one, done by that plan, with stripping up of periosteum, a long stump which appeared to contain bone was obtained. In all cases of late years some antiseptic method of dressing had been adopted, usually a strong lotion of lead and spirits of wine had been applied, but in some Lister's gauze dressings had been used. The paper concluded by the mention of cases in which, after consultation, the operation had been declined or deferred, on the plea that the patient would probably recover without it, and in which an opposite result had occurred.—Mr. Howard Marsh considered that the subject required a great deal more attention than had been given to it. In his experience amputation at the hip-joint was a very valuable step to take in certain desperate cases. The tendency to the performance of this operation had increased of late at the Hospital for Sick Children, and he himself had performed the operation six times, and had seen it performed many times besides; death very rarely occurred. He had used Davy's lever many times, and he had found it one of the best appliances that had been introduced into surgical practice. By its use the operation was rendered as nearly as possible bloodless, for it controlled not only the common femoral artery, but also the posterior division of the internal iliac artery. He had three times performed Furneaux Jordan's method, and said that it took a long time to do, and the size of the wound was increased. There was less risk of hæmorrhage from the posterior flap if Davy's lever were used, and with it the old flap method could be done much more quickly than Furneaux Jordan's operation. In the latter operation amputation lower down could be done, so as to obtain a longer stump for the adaptation of an artificial limb; this and the subperiosteal method were noteworthy points in the case shown by the late Mr. Shuter to the Society. In this case there was a central stem in the stump, which had the consistence of bone, though it was probably not composed of osseous tissue. The disappearance of the signs of amyloid disease after removal of the strumous disease was a most important and well-ascertained fact. Moreover, the presence of lardaceous disease need form no bar to the operation. Some years ago, when he was a member of the committee for investigation into the treatment of hip disease by different methods, it was ascertained that death occurred in 33 per cent. of the cases treated by any method, and so it was a well-ascertained fact that death could result from hip-joint disease.—Mr. Golding-Bird said that Furneaux Jordan's operation was very much like Fleuret's modification of Larrey's operation on the shoulder-joint. He advised that the circular incision should be made in two portions, the second circular incision to be performed after enucleation of the bone; the second circular division divides the vessels last. The vertical incision should be made first, as it enables the joint to be examined and the kind of operation to be decided upon.—Mr. R. Barwell shared almost the same opinions as those which Mr. Hutchinson had expressed. In a case in which the liver reached as low as the umbilicus there was albuminuria, with large hyaline casts, and amputation was performed for strumous disease of the hip-joint. He urged that frequent microscopical examinations of the urine should be made, for the presence of narrow casts with albuminuria contra-indicated the operation of amputation, as the small casts, he believed, indicated deeper affection of the kidneys. Statistics showed how very much more favourable were amputations done for chronic strumous disease as compared with those performed for tumour or injury. He testified to the great value of Davy's lever, though this agent had sometimes caused bruising of the iliac vein and its consequences. He agreed with Mr. Marsh that Furneaux Jordan's method, being more tedious, might be dispensed with now that Davy's lever could be used.—Mr. Black spoke of the elastic tourniquet, and said that it perfectly controlled the circulation through the lower limb. Out of forty cases of amputation at the hip-joint in which Mr. Davy had used the lever, there was but one case in which the intestine had been damaged or any injury had resulted.—Mr. Warrington Haward said there was no doubt that for strumous disease amputation was a different matter than for tumour or injury, and much more favourable. He spoke of the enlargement of organs, and said that he remembered a case in which this diminution occurred where there had been no surgical interference. He believed in the use of Davy's lever, and had employed it successfully in a for hof ruptured gluteal artery. He considered that it might in replyasily used for the right as the left limb. Mention was made of the use of a cone of wood suitably padded for compressing the abdominal aorta, which was less distressing than Lister's tourniquet. In reply to Mr. Hutchinson, he said the case in which spontaneous diminution of the liver took place there was chronic hip-joint disease, which also receded under medical treatment.—Mr. Bryant said that his experience was to the effect that amputation in such cases was unusually favourable, but he considered with Mr. Hutchinson that some surgeons were apt to postpone the operation unnecessarily. The value of the long stump was remarked upon. He would not dispense with the subperiosteal method, for it gave rise to less disturbance in the muscles about the part, and left a dense hard mass of new tissue, probably not bone, but fibrous in nature. He did not think it a matter of much importance whether the vertical or circular incision was made first. Davy's lever was not so successful as was at first believed, for, in addition to injury of the intestine, it had also caused bruising of the iliac veins. A means employed by Mr. Lloyd of Birmingham was favourably spoken of; a folded indiarubber bandage was passed round the buttock, between the anus and the ischial tuberosity, and then over the hip, so as to press on a roller placed along the line of the external iliac artery.—Dr. Marshall, in reply, said that one point had been overlooked in his paper, and that was that all his operations were done on children. He had used Esmarch's bandage, though it slipped in one case. Stress was laid on the importance of rectal alimentation during the period of vomiting and collapse. He said that Dr. Maclaren found, by experiment on the dead body, that the flap operation took but eleven seconds less to perform than Furneaux Jordan's operation. The operation he advocated was followed by less shock, and there was less chance of septic inoculation.—Mr. Hutchinson, in reply, said with regard to the use of Davy's lever, he shared the opinion which the President had expressed. He had found that an elastic strap placed round the abdomen, compressing a large towel placed over the aorta, was most effective in controlling hæmorrhage. The method of Furneaux Jordan gave a better stump, though the time required for the operation was rather longer.

Dr. Colcott Fox read a paper on a Peculiar Form of Skin Disease, with the object of drawing attention to an affection of the skin accurately described for the first time by Hovaud of Lyons, in the seventh volume of the first series of the *Annales de Derm. et de Syph.* Dr. Fox had met with seven cases in the last two or three years, and thought the disease was a distinct morbid entity resembling Willan's roseola annulata in appearance, but running a chronic course. The lesions were slightly raised, rounded, the smaller uniform in aspect, the others depressed in the centre with only the borders raised, which gave them a distinctly circinate form. Their colour varied from a pale-rose to yellowish-white, approaching to the tint of the surrounding skin, so that one could sometimes with difficulty distinguish them from the rest of the integument. Often the border alone was coloured. The eruption was constituted by discrete or confluent patches, of which the dimensions varied ordinarily from a lentil to a two-franc piece. They exceeded these dimensions only in rare cases. The maculæ were constantly dry, their surface was more or less furfuraceous. They were accompanied by a little itching, especially when they were excited and reddened by heat or bathing. The eruption seemed to commence nearly always on the trunk and extended thence to the limbs, and disappeared in the order of its invasion. Its etiology was very obscure. Hovaud's cases were met with between the ages of eight and thirteen, and Dr. Fox had seen the eruption at four years of age. He then detailed two cases of a somewhat similar condition in children, which he believed to be the pityriasis circiné et marginé of Vidal, only there was considerable symmetry. The eruption was almost universal, and the maculæ rather larger than in the affection portrayed by Hovaud. In these cases the patches were found to be invariably crowded with masses of micro-organisms. The hairs were unaffected, and there was no mycelium. Repeated attempts to inoculate the cultivated organisms had failed. He had already met with a similar organism in two cases of psoriasis in children, and it was possible that the micro-organism was commonly to be found amongst the desquamating epithelial scales of children's skins. A stained preparation was exhibited to the meeting.—Dr. Glover spoke of a case of the disease affecting the bare portion of the neck; the eruption was present in a young lady, aged twelve, and had the appearance of psoriasis guttata; it was slowly getting well.—

Dr. S. MACKENZIE said the microscopical appearances of the fungus were highly suggestive of a micrococus, as was also the fact that no mycelium had been discovered either by Vidal or Dr. Fox. Moreover, the micro-organism occurred in a variety of diseases. Further, in no case had there been any extension of the cutaneous disease to other individuals.—Mr. HUTCHINSON asked questions as to the cause of the malady and mode of cure. He was acquainted with a form of pityriasis which always commenced on the trunk and never affected the hands and feet, though it nearly always extended secondarily to the limbs. This eruption he believed to be due to the wearing of peculiar vests, and it might assume a great variety of forms; the eruption certainly spread to parts of the limbs where the vest or other offending article of clothing did not touch. If these patients wore silk next the skin, he found that the eruption disappeared.—Dr. Fox agreed with Dr. Mackenzine, and said that it was not he who had given the long name to the affection; of its cause he knew nothing.

Dr. Sidney Phillips showed a living specimen of Sporadic Cretinism, and Mr. Strugnell one of Total Paralysis of the Fifth Nerve.

MEDICAL SOCIETY OF LONDON.

Myxœdema.—Uncomplicated Brachial Monoplegia from Lesion of the Internal Capsule.

AN ordinary meeting of this Society was held on the 13th inst., Dr. W. Miller Ord, President, in the chair.

Dr. WHIPHAM read a paper on a case of Myxœdema, and showed microscopical specimens of some of the organs of the body. The patient was a female aged twenty. She had suffered from rickets, and the tibiæ were still bowed on her first admission to hospital. She had been languid and weak ever since the catamenia appeared. Up till two or three years ago she had had abundant very long golden hair, but this all fell out, and has grown but very slowly since. On admission she was ill-nourished and apathetic; red hair grew low on the forehead, and there was much downy hair on the temples. Her manner was slow. The abdominal swelling of which she complained had been coming on for three or four years. Slight œdema of the legs and occasional puffiness of the face were present. Polyuria had existed for several years. For the last three weeks the abdominal swelling had increased; there was anæmia, vomiting, and some swelling of the legs; the pulse was 8 per minute, very weak, and compressible; the feet and hands were large, the skin over them coarse, red, and cold; the urine was acid, albuminous, and had a specific gravity of 1016; the teeth were markedly notched. After some purgative treatment, the ascites was treated by Southey's tubes, and ten pints of fluid withdrawn. She then left the hospital, and was readmitted a year later, having lived in a state of complete idleness. She had had profuse menorrhagia. At the end of 1882 she manifested all the signs of myxœdema. She had previously been treated by the late Dr. Barclay as a case of chronic peritonitis. The thyroid body could not be felt. The ascites slowly and persistently increased; eight pints of viscid clear fluid were withdrawn; at one time diarrhœa was present. The temperature was rarely above normal. In August last she was sent into the hospital with pneumonia; the ascites was relieved by tapping; pericarditis supervened; and the patient died, the temperature having been between 102° and 103°. At the autopsy the body measured five feet two inches; the calves were very large; the left gastrocnemius weighed twenty-one ounces. There was a little lymph and fluid in the right pleural cavity. The upper lobe of the right lung was in a state of red hepatisation. In the submucosa of the stomach some patches of "mucous" tissue were seen. There were twenty pints of mahogany-coloured fluid in the peritoneum. In the brain behind the right locus niger there was a small deposit of hæmatoidin. Sections of the organs were made by Dr. Heneage Gibbes. In some parts of the brain there was an increase of the fibrous tissue in the perivascular spaces, and in places the vessels were enormously distended; in places the vascular walls were thickened. There was an increase of the fibrous tissues of the branches of the capsule of Glisson; the hepatic cells were compressed by intervening hyaline exudation. The signs of chronic interstitial nephritis were also present in patches, and in places the tubules were separated by hyaline material (œdema). The interstitial tissues of the pancreas were swollen and œdematous and bacteria were found. The ovaries were œdematous. The tongue had a general appearance of œdema and the muscle fibres showed a tendency to transverse cleavage. Œdema beneath the sarcolemma was detected in the muscle-fibres of the upper lip. In the pulp of the right middle finger the fibres were separated by œdema. Tubercular lesions were present in the lymphatic glands. The aorta showed thickenings and atheromatous changes. The case was compared with the description of the tissues given by Dr. Ord and Sir W. Gull.—Dr. ORD said that he now believed there were more changes in the connective tissue of the central nervous system than he had formerly admitted. He inquired whether any chemical investigation of the amount of mucin had been made.—Mr. VICTOR HORSLEY remarked on the presence of disease of the vessels in myxœdema. In cases of myxœdema symptoms of premature senility, with tremors and general weakness, were present. The thyroid gland in old age would be found to be greyish in colour; its weight was notably diminished. He thought that microscopical examinations of the thyroid in old age were much wanted.—Dr. HADDEN said that he had examined the thyroid gland in six or seven cases of myxœdema. Outside the acini there was a round-celled infiltration, which became organised into fibrous tissue; the cells of the acini underwent proliferation and became fibrous in structure. He had also found fibroid overgrowths in the portal canals. He was now investigating the condition of the thyroid gland in persons dying from any disease.—Dr. A. ROUTH asked whether the ovaries always presented the appearance Dr. Whipham had described, and made some remarks on the state of the catamenia.—Dr. WHIPHAM, in reply to the President, said no chemical examination had been made. He could give no further information concerning the ovaries and menstruation.

Dr. HUGHES BENNETT and Dr. M. C. CAMPBELL read a paper on a case of Brachial Monoplegia due to Lesion of the Internal Capsule. The patient was a man aged eighty, who, when in a condition of fair health, suddenly lost consciousness; on regaining his senses he was found to have lost his speech, and the left side of the face and the left upper extremity were paralysed. With the exception of the paralysis of the arm, he recovered from these symptoms. There was no rigidity of the affected muscles, and the sensibility was everywhere normal. This condition persisted for about six weeks, when the patient died from old age and general break-up of the constitution. The essential lesion found on post-mortem examination was a limited defined softening, about the size and shape of a small horsebean, but flatter, occupying the upper part of the internal capsule without seriously involving any of the neighbouring structures. It was stated that uncomplicated brachial monoplegia caused by a lesion of the internal capsule was of extremely rare occurrence, and from the circumstances likely always to be so. That such a lesion should have existed in the present instance suggested some interesting physiological and anatomical considerations. As all the conducting fibres from the different motor centres of the cortex are collected together at the internal capsule and pass through it in a very limited space, it is evident that if a small flat lesion causes paralysis of one limb only without affecting the others, the fibres from such motor centres must pass through the capsule in separate bundles. A diagram was shown and explained to attempt to define the course and position of these conducting fibres, as they run from the cortex cerebri through the corona radiata to the internal capsule. Dr. Bennett contended that both anatomical and pathological facts seemed to indicate that these conducting parts, which at first run from the cortex arranged in a lateral direction, as they entered the capsule bent upon themselves, passed through it in bundles, arranged in an antero-posterior fashion, those of the face being the most anterior; next in order coming those of the arm, leg, and trunk. In this case a limited disease destroyed only the fibres conducting motor impulses to the arm, leaving those of the face and leg on each side of them intact, thus supporting the above theory.—Dr. ORD spoke of the many-sided value of the case in question.—Mr. V. HORSLEY referred to a paper published by him in THE LANCET, vol. ii., p. 7, 1884, and said that the case bore out some views on "substitution" therein stated. The case also overthrew the theory of Munk, that the cortical centres were both sensory and motor, for the lesion merely removed the power of originating movement, and did not affect sensation in any way. The case also went against the view of Hughlings Jackson on bilateral representation of the limbs, for there was no recovery of power, even after some weeks had elapsed.—Dr. Kingston Fowler showed a patient suffering from nervous disease which began in the first instance as a case of left brachial monoplegia. He had no doubt then that there was a cerebral lesion of specific origin. Headache, diplopia, and partial blindness, with squint later on, were the early symptoms of the case. Some numbness along the course of the left ulnar nerve was present. After an attack, in which the patient was giddy and lost consciousness, the left arm was found to be paralysed; the left leg and face were also slightly affected. There was greatly delayed sensation on the left side, and the special senses were also affected on the same side. There was no optic neuritis. Under antisyphilitic treatment there was some recovery of power and return of sensation in the left limbs. At the early part of the present year an attack left him powerless in the right upper limb. There was also delayed sensation and delayed appearance of the reflex actions. A blow on any part of the body caused the head to be thrust forward. There were no knee-jerks.—Dr. H. Bennett briefly replied.

Reviews and Notices of Books.

The International Encyclopædia of Surgery. Edited by John Ashhurst, M.D. Vol. V. Pp. 1207. London: Macmillan. 1885.

This handsome volume contains articles by fourteen contributors, of whom seven are American physicians and surgeons of repute, five Englishmen, one Scotchman, and one Irishman. They are in order as follows. 1. Injuries of the Head, by Charles B. Nancrede, M.D., Professor of General Surgery in the Philadelphia Polyclinic. 2. Malformations and Diseases of the Head, by Frederic Treves, F.R.C.S., Lecturer on Anatomy, London Hospital. 3. Injuries and Diseases of the Eyes and their Appendages, by E. Williams, M.D., Professor of Ophthalmology in Miami Medical College, Cincinnati. 4. Injuries and Diseases of the Ear, by Albert H. Buck, M.D., of New York. 5. Diseases and Injuries of the Nose and its Accessory Sinuses, by George M. Lefferts, M.A., Clinical Professor of Laryngoscopy, Columbia College, New York. 6. Injuries and Diseases of the Face, Cheeks, and Lips, by Alfred C. Post, M.D., Emeritus Professor of Clinical Surgery in the University of the City of New York. 7. Injuries and Diseases of the Mouth, Fauces, Tongue, Palate, and Jaws, by Christopher Heath, F.R.C.S., Holme Professor of Clinical Surgery in University College, London. 8. Surgery of the Teeth and adjacent parts, by Norman W. Kingsley, M.D., Professor of Dental Art in New York College of Dentistry. The most original and perhaps the best article in the volume is the first, by Charles Nancrede. His experience and reading have been alike large, and the rules he gives are well worthy of consideration, though they are not always in accord with the text-books. Thus, in cases of simple depressed fractures he approves the use of the trephine and the elevation of the depressed portion; he thinks that the dangers of a simple depressed comminuted fracture are greater than those which follow its conversion into a compound fracture. Numerous and interesting cases of injuries to and of foreign bodies in the brain are given, and excellent rules are laid down for the determination of the fissure of Rolando and other points in cerebral topography. Dr. Williams's essay on Injuries and Diseases of the Eye occupies 120 pages, and is very complete. He commences with a short description of the anatomy of the orbit, eye, and its appendages, and then proceeds to consider the affections of the orbit; and some interesting cases are rather fully given. Wounds of the eyeball are then discussed, and good rules to determine whether a foreign body has penetrated or not are appended. He dwells very properly on the danger of wounds in the ciliary region, and records a case that young surgeons should bear in mind. A young lady, as a result of a perforating corneal ulcer, had a large prolapse of the iris, which, though disfiguring, was not apparently troublesome. Dr. Williams in an evil moment, clipped it off with scissors. Iritis followed of a persistent character, and after some time sympathetic ophthalmia of the opposite eye followed, leading to complete disorganisation and blindness. He may console himself with the reflection that the same untoward result has occurred in the practice of other ophthalmic surgeons besides himself. Dr. Williams thinks that an attack of sympathetic ophthalmia is preceded by a warning irritation in the sound eye, and that if this be recognised, and the offending eye be promptly removed before inflammation is established, the patient is saved from blindness. We are inclined to agree with him in the case of adults, but with children we think the rule should be general that in punctured wounds with knives, scissors, pins, or other similar instruments in the ciliary region the eye should be removed. It is almost impossible to keep a child quiet or to maintain a bandage upon both eyes, and irritation in them runs insidiously and rapidly into inflammation. The symptoms and treatment of purulent ophthalmia in children are of course well given, but the writer does not mention the prophylactic measures adopted with such success by Crédé, of using antiseptic vaginal injections just before delivery. The treatment of diseases of the cornea is treated at unusual length and with great ability. In regard to cataract, Dr. Williams operates without anæsthetic, and without dilatation of the pupil. He makes the section of the cornea at, or a little in front of, the sclero-corneal junction; he performs iridectomy; he carefully clears the pupil of fragments of the lens; he changes the dressings twice a day, and in ten days removes them altogether; he does not allow the use of glasses till six weeks have elapsed. The method and the details given are all unexceptionable, and may be followed implicitly by all who are about to operate. For the relief of glaucoma the writer practises iridectomy, but speaks doubtfully about sclerotomy. The chromolithographs, both of the diseases of the conjunctiva and iris, and of the ophthalmoscopic appearances of the eye in disease, are poor and unrepresentative. Mr. Bencke, the lithographer, could, we imagine, turn out something better than these. No satisfactory drawings of the fundus can be produced with only two or three tints.

The article by Dr. Buck on Injuries and Diseases of the Ear follows that on the Eye, and runs to about seventy pages. Dr. Buck considers Wilde's ear speculum, if made of silver, highly polished, and very thin, as the best means of exploring the meatus, when aided with a good forehead mirror, with a focal distance of twenty centimetres. He gives a very full description of the various maladies of the external ear, including eczema, diffuse inflammation, perichondritis, contusions, deformities, frost-bite and burns of the auricle, and impacted cerumen, common boils, ulcers, wounds, and new growths of the auditory meatus. In speaking of the modes of examining the middle ear, Dr. Buck gives Valsalva's and Politzer's methods and describes the mode of employment of the Eustachian catheter. He supplies some important and very useful directions with regard to the contra-indication for the use of Politzer's method, which, we fear, are often neglected. It should never be adopted, he says, until after both drum membranes have been examined, nor when there is a deeply depressed membrane, which may possibly be adherent to some of the deeper parts of the middle ear, nor when the drum membrane is atrophied or presents a thin cicatrix, nor when actually inflamed. When abscess of the tympanum exists, he has no hesitation in perforating the membrane, avoiding the dangerous region of the upper half of the posterior superior quadrant. The diseases of the mastoid rocess follow, with a very short section on affections of the uditory nerve. The article is illustrated by many woodcuts of instruments, some of which are novel, and an xcellent chromolithograph of the morbid appearances presented by the membrana tympani. Though brief, Dr. Buck has managed to compress into the space at his disposal nearly all that is important in his special subject, We may ay the same of Dr. Lefferts' essay on a subject not generally given in full in surgical works—namely, the Diseases nd Injuries of the Nose and its Accessory Sinuses, which, of course, involves a description of the examinations of hose parts known under the names of anterior rhinoscopy and pharyngo-rhinoscopy. The article on Injuries and Diseases of he Mouth has been entrusted to Mr. Christopher Heath, and s thoroughly and comprehensively treated, though Dr. Port till finds something to say on Injuries and Diseases of the ace, Cheek, and Lips, and Dr. Macleod on the Injuries nd Diseases of the Neck. Both Mr. Morris's article on njuries and Diseases of the Abdomen and Mr. Treves on Malformations and Diseases of the Head are very creditable productions. No better exponent of the modern views on the Varieties and Treatment of Hernia could have been ound than Mr. John Wood. The volume as a whole well ustains the repute of those which have preceded it, and it may be consulted with advantage by even the most accomplished surgeon.

Topographical Anatomy of the Brain. By J. C. DALTON, M.D., Professor Emeritus of Physiology in the College of Physicians and Surgeons, New York, and President of the College. Philadelphia: Lea Brothers and Co. 1885.

THIS is one of the most magnificent works on anatomy hat has appeared during the present generation, and will ot only supersede all its predecessors on the topographical anatomy of the brain, but make any further work on the ame lines unnecessary. It is published in three volumes, and contains forty-eight exquisite illustrations of the brain, *en masse* and in sections. The specimens were prepared by Dr. Dalton and photographed by Mr. G. Mason, photographer to the Bellevue Hospital, New York. Heliotype transfers were then made from the original negatives, and the plates printed by the Heliotype Printing Company of Boston. In this manner not only has perfect accuracy been secured, but one of the finest and most artistic works of recent times has been presented to the medical public. Its value as a work of reference is considerably increased by the very careful outline sketches which accompany the plates, and which enable them to be easily followed and understood. These sketches are very complete and accurate, and have been reproduced from tracings made by Dr. Richard Lennox of the Roosevelt Hospital, New York. The first volume is devoted to the exterior convolutions, and contains ten plates corresponding outline sketches, and the explanatory descriptions; in the second volume fifteen horizontal sections, and in the third volume twenty-three vertical sections, are similarly shown and explained. The descriptions by the author are clear, precise, and accurate; and the methods by which the sections were made and the specimens reproduced are given very plainly in an introductory chapter, which cannot fail to be of the greatest value to anyone who is desirous of making similar preparations. Criticism on such a work is superfluous. We can only congratulate Dr. Dalton, his assistants, and the publishers on the energy they have shown in undertaking such a work, and the success with which they have overcome a task presenting so many mechanical difficulties. We envy our American *confrères* the authorship and execution of so beautiful and useful an addition to medical literature, and much light is thrown on some obscure relations of parts of the brain which have never before been seen in correct juxtaposition.

ROYAL COLLEGE OF SURGEONS.

THE Committee on Charters and Bye-laws have adopted the following as their fifth report to the Council, viz.:—

The Committee have to report that, having considered the several proposals of the Association of Members of the College, they do not recommend that, as therein suggested, the whole Council be elected every three years; nor that the number of the Council be increased to twenty-five; nor that the Members, as well as the Fellows of the College, should take part in the election.

The Committee have further to report that, in pursuance of the resolution of the Council of the 8th of January last, the President invited delegates from the Association of Fellows to meet the Committee on the 3rd instant, that at the meeting held on that date ten delegates from the Association attended at the College, and that the proposals of the Association and the report thereon of the Committee, dated the 10th of December, 1884, were fully discussed, the delegates stating their reasons for their several recommendations.

From this discussion it appeared that the recommendations of the Association, to which the delegates attached the most importance, were those relating (1) to the constitution, mode of election, and duration of office of the Court of Examiners and Board of Examiners; (2) to the proposal that six instead of three Members of the Council should retire from office annually; (3) to the election of the President by the Fellows instead of by the Council; (4) to the right of meeting by the Fellows and Members without the sanction of the Council; and (5) to the time and mode of making public the minutes of the Council: all of which recommendations the delegates urged upon the Committee with a view to their adoption by the Council, renewing the request, "that no steps should be taken by the Council to obtain a new Charter until the various alterations proposed or accepted by the Council, together with the recommendations of the Association of Fellows, shall have been submitted to a general meeting of Fellows and Members."

The Committee, having fully considered the arguments brought before them by the delegates in favour of the recommendations of the Association of the Fellows, have to report to the Council that they adhere to the conclusions arrived at in their fourth report so far as they relate (1) to the constitution and duration of office of the Court of Examiners and the Board of Examiners; (2) to the duration of office of a Councillor; (3) to the election of President; and (4) to the right of meeting of the Fellows and Members, excepting that in page 8 of such report, in the paragraph respecting the meeting of Fellows and Members, they propose to substitute for the words "*provided that the objects of such meeting be approved by*" the words "*with the consent of*," the Council.

With respect (5) to the publication of the Minutes of the Council, the Committee recommend that, in lieu of the confirmed Minutes being suspended in the hall, as proposed in their fourth report, the Council should revert to the practice formerly in force, in accordance with the following resolution of the Council of the 10th of February, 1870, viz.:—"That the Minutes of each meeting of the Council be posted in the hall of the College within five days of each meeting; those Minutes having previously been submitted to the President or Senior or Junior Vice-President for approval."

The Committee have, in conclusion, to report to the Council that they do not recommend that there should be any delay in submitting to the proper authorities the proposed alterations in the Charter, inasmuch as the several alterations in the Charter proposed by the Council were submitted to a meeting of the Fellows and Members on the 24th of March, 1884, and acceded to at that meeting, and as the only two further alterations in the Charter, subsequently proposed, relating respectively to the qualification of a Fellow for election to the Council and to the mode of nomination of candidates for the Council, have been adopted by the Council in accordance with the proposals of the Association.

March 19th, 1885. T. SPENCER WELLS in the chair.

THE LANCET.

LONDON: SATURDAY, APRIL 18, 1885.

The lectures which Sir Andrew Clark has lately delivered before the Royal College of Physicians were, as was to be expected, couched in well-chosen language and full of closely-reasoned argument. Moreover, they contained clinical and pathological descriptions such as only a close and accurate observer could produce. That they will be widely studied is unquestionable, and the more so from the spice of polemics with which they are seasoned. For from one point of view they constitute a manifesto on the part of the lecturer against the prevailing tendency to regard the phthisical process as owning but one cause—viz., tubercular infection,—in that they bring into prominence the fact that the lung may undergo destruction by invasion of fibroid tissue originating in pleural inflammation. This is the underlying thesis of these Lumleian lectures, and although it may be thought to consist in little more than a restatement of a position which Sir Andrew long since took up, it receives new significance at the present day, when the true nature of the tubercular virus has apparently been revealed, and for the most part generally accepted. Sir Andrew Clark anticipated that his advocacy of such doctrine would meet with much adverse criticism from the modern pathologist; but we fear he is doomed to be disappointed. For even had his position been less powerfully supported by facts than it was, there does not seem *primâ facie* to be any room for objection to the conclusions at which he arrived. Time was when the term "phthisis" included not only tubercular affections, but gangrene, malignant growths, and other destructive lung disease; and the exclusion of such conditions was later followed by the further distinction into tubercular and pneumonic phthisis. It is now generally admitted that the latter classes have the same etiology as the former, the difference being mainly one of chronicity. There still remain such conditions as those to which the lectures were devoted, and if the term phthisis must be retained for them, then there is no reason at all why we should hesitate to admit a tubercular and a non-tubercular phthisis, or, if it be preferred, a bacillary and a non-bacillary form. The only limitation that can rightfully be placed upon such a view is that the alleged non-tubercular character of any given case shall be clearly proved, and that it be not confounded with those undoubted conditions where tubercle undergoes fibrotic change. It would be unsafe to assert that any one of the instances quoted by Sir Andrew falls under this last-named category, and therefore the question is narrowed to one of the comparative frequency of the two forms of chronic lung disease; that which commences in a simple "primitive" pleurisy, and that which begins with pulmonary tuberculosis, with secondary involvement of the pleura.

The manner in which Sir Andrew Clark developed his thesis was well chosen. He commenced by giving details of cases of dry pleurisy, of varying extent and intensity, leading up to cases which, after a number of years, succumbed, and proved to have most extensive pulmonary disorganisation, combined with equally extensive pleural changes. He then discussed at length the morbid anatomy of the process which has such destructive issues. It is somewhat difficult to follow him in the distinctions he lays down between the various forms of the pleural affection, based on a study of the nature of the exuded material. Indeed, one feels disposed to question the propriety of seeking to establish such distinctions; but, grounded as they are upon personal scrutiny, we would not venture to dispute their accuracy. That one form of exudation partakes of a fibrinous, another of a cellular (the term "croupous" is surely inapplicable) character, and that a third deserves to be called "proliferative" is perhaps justified, but the distinctions are often so blurred as to be wanting in those clear outlines which render them suitable for definition. Nor did the lecturer apparently allude to the cases which are obviously tubercular, where the portions of pleural membrane still free from adhesion exhibit undoubted granulations. To be sure, such a condition would have been foreign to his subject, but its recognition should have been allowed. The pulmonary parenchyma is liable to invasion by fibroid tissue spreading along the interlobular septa in the first place, causing thickening of the alveolar walls, peribronchial and perivascular tissue subsequently, and, in fine, so altering both the texture and nutrition of the lung that the organ becomes converted into a dense sclerotic mass, probably permeated by dilated bronchi, or else the seat of excavations, which may have proceeded from bronchiectasis, or been due to local necrosis of tissue from interference with the blood-supply, produced by the fibrotic invasion. The description of the manner in which this disorganisation proceeds, of the resemblance at certain stages to the appearances presented by fibroid tubercle, and of a differentiation of the issue into the fibroid lung, the bronchiectatic lung, and the fibroid phthisical lung, was given by the lecturer with ample detail, and the clinical recognition of such cases was exemplified in the third lecture.

The unilateral character of the affection, its extremely slow progress, the absence of pyrexia or emaciation, and the frequently entire lack of evidence of an inherited taint, coupled of course with the failure to detect bacilli in the sputa, are facts which strikingly differentiate such cases from ordinary tubercular phthisis. That, however, does not preclude the admission of the fact—a fact which comes so materially to dispel the gloom of the ordinary prognosis of phthisis—that tubercular disease may become quiescent, or may initiate fibrotic changes in which itself shares, and, by reason of them, progress with comparative slowness. The truly tubercular are, however, always prone to an outburst of the infection; for many such cases eventually terminate after an illness of a few weeks' duration, by no means sufficient to account for the extensive fibrotic lesions that occur in the lung. It would have been interesting to have learned whether the subjects of pleurogenic phthisis, or of the fibroid lung state resulting from simple pleurisy, ever become the victims of tubercular infection. In such a case the mingling of the characters of the two great factors in phthisis would add greatly to the difficulty of unravelling the truth. Sir ANDREW CLARK has done good service in so pointedly showing the dependence of this class of case upon antecedent pleurisy; and we think we may go so far as to accept with him the notion that such pleurisy is neither tubercular in itself nor the necessary precursor of pulmonary tubercle. At the same time, the precise discrimination of the two forms of chronic lung disease, and particularly the possibility of tubercular pleurisy eventuating in changes similar to those ascribed by Sir ANDREW to non-tubercular inflammation of the serous membrane, are subjects which may still afford material for further investigation.

◆

As may be inferred from the brief announcement which we made last week, and from the fifth report of the Committee on Charters and Bye-laws, republished in another column of this week's issue, the Council of the College of Surgeons of England has spoken what it would fain believe is the last word anent the alterations to be made in the Charters. The conclusion to which the Council has arrived is that it cordially approves the various alterations which itself initiated with a view of extending its own power, influence, and authority; and it has, after some pressure, expressed a willingness to revert to two Resolutions which it adopted over fifteen years ago—namely, first, to suspend a supervised copy of the Minutes in the hall of the College: and, second, to allow the holding of meetings of Fellows and Members in the College on requisition. It has yielded to the demand that an annual meeting of the Fellows and Members shall be held for the reception of the report of the Council, though it has given no undertaking that the report shall be *discussed;* and it has agreed to accept the proposal that the voting at the election of members of Council may be conducted in person or by voting paper. These, together with a suggestion made by the Association of Fellows, that any Fellow, who has been a Fellow for ten years or a Member for twenty years, shall be eligible for a seat in the Council, are all the material alterations that the Council purposes to introduce into the new Charter.

To those persons who have had actual experience of the inherent repugnance to alteration of any kind exhibited by the executive of all corporate bodies these changes may appear at once numerous and far-reaching. Nor can it be denied that some of them are real and fundamental and big with possibilities. Indeed, their only drawback is that they have come eighty-five years behind their due time; for it is a historical fact that there is scarcely a single important alteration (always excepting those that are strictly autochthonous in the Council), which was not repeatedly advocated by independent persons during the discussions and agitations which immediately preceded the original establishment of the College. But, considerable as the proposed alterations may be, they embrace only a part of the change which persons believe to be indispensable to the growing importance of the College and the professional and academic status of the Fellows and Members. Of this the report of the Committee on Charters and Bye-laws above mentioned contains unmistakable evidence. This report shows:—(1) The Board of Examiners is to remain unreformed; (2) the tenure of office of members of the Council will remain unabridged; (3) the Council will continue to elect the President of the College; and (4) the Members of the College shall have no part in the election of the members of the Council. The meaning of most of this must be sufficiently obvious. Examiners will continue eligible for seats in the Council, so that in the future, as in the past, one-half or more of the executive of the College may be persons who, as examiners, will absorb at least one-half of the ordinary revenue of the College. And as these examiners are elected by the Council, they may, to all intents and purposes, be self-elected; self-elected, that is, each to an emolument of between £400 and £500 per annum. And this happy privilege may be extended, as in the case of a late examiner, to a period of fourteen or fifteen years. A recommendation of the Association of Fellows was intended to render such an abuse of interest, power, and privilege impossible; but the Council, consisting largely of present and past Examiners, has a second time refused to accept it. Equally uncompromising is its rejection of the recommendation made by the Association of Fellows as well as by that of Members, that the tenure of office of members of Council shall be shortened from eight to three or four years. "With regard to any influence of the constituent over the conduct of the representative, there is little difference between a seat in Parliament for seven years and a seat for life," said JUNIUS; and, *mutatis mutandis*, the members of the Council of the Royal College of Surgeons of England are evidently of the same opinion.

Of the evils of leaving the election of President of the College in the hands of the Council it is unnecessary to say more than what has been advanced times without number. The custom of electing the senior member of the Council to the office of President may be a convenient and easy way of making things pleasant, but it is neither dignified nor discriminating. Through lack of courage the Council has more than once placed in the presidential chair a person notoriously unfit.

The Association of Fellows has cause to be dissatisfied with the reception that its recommendations have received. It is hardly likely that the Association will accept the decision of a bare majority of twenty-four Fellows as final. That the Association of *Members* is not disposed quietly to submit is sufficiently evident from the letter signed by its honorary secretaries which appears in another column. A public meeting is to be held in the Westminster Town Hall on May 4th, at 4 P.M., to discuss what further steps may be taken in order to obtain such reforms as are felt to be most urgently needed in the administrative department of the College. There may be, and doubtless are, difficulties in the way of carrying out the programme drawn up by the Association of Members; and the burden of showing how these difficulties may be overcome lies with the Association. But making full allowance for these and other considerations, it is impossible not to feel that the Council has treated the Association of Members somewhat cavalierly.

◆

IN a paper recently communicated to the Society of Medical Officers of Health, Mr. HENRY E. ARMSTRONG of Newcastle-upon-Tyne deals at length with the subject of the status of his fellow-officers throughout the country, a matter to which we also adverted in our issue of the 4th inst.; and Mr. ARMSTRONG's communication may be taken as a summary of complaints which are very generally felt at the present time. First and foremost, it must be admitted that the position which the medical officer of health holds as regards the tenure of his office is most unsatisfactory; indeed, it is difficult anywhere else in the public service to find its counterpart. Sanitary authorities appoint their town clerks, treasurers, engineers, and surveyors to an office which it is understood they hold during good behaviour; but when it comes to the medical officer of health the appointment is for a limited period, often of one year's duration, and very seldom exceeding five years, and the officer is by this reason alone seriously hampered in his work, for he knows that he will have periodically to seek re-election at the hands of those with whom he is most concerned in his official capacity. It may be said that the difference between the officers referred to and the medical officer of health is due to the circumstance that, in the case of the latter, part payment of his salary is made out of a Parliamentary grant; but, as we have more than once pointed out, the same applies to the Poor-law medical officer, and yet his appointment is not so limited as to necessitate a frequent resort to the tactics involved in securing re-election. That the interests of the public are seriously hindered on account of the anomalous position in which the health officer is placed is a matter of common notoriety, for there are other authorities besides the one referred to by Mr. ARMSTRONG, who seek an officer who will carry out their determination to "do nowt that cost owt, and owt that cost nowt." In short, many an officer whose conscientious performance of his duties has involved some substantial expenditure has had to make way for one or more successors, who have consented at nominal salaries to take his place directly the expiration of his term of office has enabled the authority to replace him. So also, taking the large towns of England, it appears that the several officers of sanitary authorities to whom we have already referred have a maximum salary varying from £1200 to £3000 per annum; whereas the average yearly salary of medical officers of health in the sixteen extra-metropolitan cities and boroughs, having populations of 100,000 and upwards, who give their whole time to their official duties, ranges only from £400 to £900, and this notwithstanding the fact that none of the other appointments involve more preparatory training or a higher legal and scientific qualification than that which properly attaches to the post of officer of health. In other words, it is evident that the position of the officer having charge of the public health compares, in almost every respect, unfavourably with that of other professional public officers.

By way of remedy, Mr. ARMSTRONG proposes that health appointments should be more equalised, small and sparsely populated districts being combined for this purpose; that the Local Government Board should exercise a greater control over appointments made with their sanction; that local authorities should be made to learn that they cannot with impunity ignore the sound advice of their health officers; that the authority of the officer of health should be extended, and especially that he should always have a direct control over inspectors of nuisances; that the recompense and prospects of the officer of health should be improved; and lastly, that his tenure of office should be placed on a more satisfactory footing. Some of the details embodied in Mr. ARMSTRONG'S suggestions may be open to criticism, but the conclusions he arrives at are sound; and it is certain that unless the position of officers of health is soon placed on a different footing, it will be found that really skilled medical practitioners will not care to devote their time and energies to a branch of the profession from which they run the risk of being ejected whenever they perform their duties fearlessly and properly, and in which the salaries offered rarely compensate for the difficulties they have to contend with, and never make up for the want of security as regards tenure of office.

◆

DURING the last quarter of a century the relations subsisting between families and their ordinary medical attendants have been growing less and less intimate. There was a time well within the remembrance of men still in active practice when no act of discourtesy to the family doctor would have been regarded as more marked than for any member of a household he attended to seek another opinion, or, as it is commonly called, "further advice," without first giving an intimation of the desire to the family attendant. The question as to who the consultant should be was decided by mutual agreement. It was not an uncommon rule for a family to settle on their consulting physician or surgeon once for all, and their relations became only second in intimacy to those held by the family doctor. A feeling of friendship and of mutual trust grew up very naturally between consultants and family practitioners under these circumstances, conducive alike to the welfare of patients and the comfort of their professional advisers. But all this is now changed. The members of a family feel themselves at liberty to consult whom they please, with or without the consent of their family attendant; nor are patients content with one opinion, but frequently seek one after another, obtaining what seems to the patient "a difference of opinion" in every instance, and often making a simple case appear a complication. Distrust of the judgment of the profession results. Instances occur of several opinions, each irrespective of the others, being obtained in this way. All this is much to be regretted, not as destructive to pleasant and useful professional relations alone, but in the interest of patients.

For the bringing about of these undesirable changes the consultant is chiefly responsible, though some of the blame must lie with the patient. There was a time when the consulting physician or surgeon would have regarded it as unbecoming his dignity to lend himself to any system which embodied discourtesy to a professional brother, and when he would have shrunk from aiding a course which in many instances enables a patient to seek his own injury under the delusion that he is finding the best means of relief. It is not uncommon for the consultant to be separated from the patient by long distances, which render frequent interviews impossible. A prescription is given, and general directions; but the patient as a rule depends on the former, which, if it gives relief, often travels the round of his friends supposed to be similarly affected, though a few hours after being written the prescription may cease to be well adapted to the case, and in some instances even hurtful. It is well worthy of the consideration of consultants and patients whether a system so mischievous should not be abandoned. That it should be discouraged by the profession there can be no doubt, and each member should consider how this discouragement can best be given. Patients are free to seek the opinion of any medical man, but medical men who are not the regular attendants of the family should hold themselves equally free not to give this opinion, except in conjunction with or through the regular attendant of the family.' Much heart-burning would be saved to doctors, and distress to patients, if this rule were more generally observed. It may not at all times be easy to refuse to advise when the patient has determined to seek what he regards as an unprejudiced opinion on his case. Under such circumstances the patient should be made to understand that an opinion thus given is not to be regarded as conclusive, but defective, in so far as it is not based on a knowledge of the family history, without which many a case must remain obscure. No diagnosis which ignores the family and personal history of the patient can be regarded as satisfactory, and this history as a rule can be best supplied by the family attendant; it is a factor in diagnosis which often enables a family practitioner to arrive at a right conclusion, when the highest talent and learning might be at fault.

The consulting surgeon or physician of the past is gradually merging into a specialist, and this fact has had something to do with these altered relations of practitioner, consultant, and patient. While specialism is a road to popularity and fortune, there is no prospect of its being abandoned; nor, while rightly used, is it desirable that it should be. But in proportion as a medical man's experience of a single disease and knowledge thereof increases, so his acquaintance with disease as a whole is liable to suffer diminution. Hence the greater need of the interposition of a family attendant between the patient and the specialist, for there are points for consideration besides those directly bearing on the cure of the localised disease, on which the specialist is too apt to concentrate all his attention, often to the disadvantage of the patient.

In country districts, where the advice of another general practitioner in the adjacent town is sought without the knowledge of the family attendant (if the fact oozes out, as is most likely), the relations between the two medical men are apt to become very strained, as well as those between the family practitioner and the family. If the town practitioner aspires to the position of consultant among his country brethren, he will need under such circumstances considerable tact. He will desire to avoid offence to a family, it may be of local distinction, whose good opinion he may wish to maintain. He may have to choose between offending a family whose friendliness is of importance to him, or a fellow practitioner. Yet his course is a plain one. He should endeavour by all means in his power to bring about a consultation between himself and his country neighbour, who has acted as the family attendant, in which attempt, if he is in earnest, he will seldom fail.

◆

ADVERTISEMENT of a certain kind and degree is as essential to professional work as to trade. The mere presence of a professional man in any neighbourhood where he is known as such is an actual guide to those who may require his services. The most modest literal indication of a practised calling, even on the hall-door of a practitioner, is advertisement, though of a severely classic dignity. So much is necessary for recognition. A mark of some sort belongs to every office. Every order of society has a descriptive term allotted to it. Indeed, a more austere abstemiousness in the use of titles would lead to great public inconvenience, particularly in the case of our own calling, in which emergencies are common, and the best physician for the time being is often the one who can first be found. Let us, however, cross the line of necessary convenience and begin to expatiate in the language of recommendation, of advertisement properly so called, and we enter at once upon doubtful ground. Leaving the terms of plain proposal, we begin to traffic with popular fancy, and we take up a position which, never noble, is most unworthy of those who apply a teaching which has any claim to general acceptation. The difference between self-advancement in an honourable and a dishonourable sense is, therefore, a difference of degree. It is not on that account the less real. But where does fault begin? A certain reputation, over and above the mere working badge, belongs to each one in proportion to his ability and attainments. Is this to be demurely shadowed, or is it to be publicly set forth? We may say, in answer to this question, that so much prestige as naturally grows out of personal effort, without any attempt on the part of the person most interested to force its growth, is justifiable. Thus the publication of researches among fellow investigators is a fair reward of labour. The spontaneous recommendation of benefited patients is likewise a legitimate advantage. To parade the merit of the discovery, or of the applied skill, before the public eye in order to promote a private gain would be to make that gain the chief professional ambition, and would not be justifiable.

We may profitably compare the conduct of gentlemen in legal practice with that of our medical brethren in this matter, and also consider some of the inducements which are apt to influence the views of one or the other class with regard to it. We are probably right in saying that the great majority of the members of both professions are equally opposed to advertisement in its ordinary and offensive sense. Probably also the legal profession as a whole is less open to reproach on this head than our own. There is less emergency and urgency in legal than in medical work; litigants are usually content to occupy some time in selecting a good lawyer. Minutes or hours do not often mean life or death in the business for which they seek him. This may account for the absence of any signs equivalent to the private dispensary, *open surgery*, or *the* familiar beacon light of medicine about the house of the practising solicitor. Medical emergencies do not, we think, require the use of all this pretension; but we can imagine that some practitioners have been misled by thinking that they do. Advertisement by means of a circulated card, or of a door-plate or slab of sensational size and covered with credential titles, hours of consultation, &c., is another objectionable method. This practice is not unusual among members of both professions at the start or even in the later progress of their independent career. We admit that it is, on the whole, exceptional, as is fortunately the still less excusable custom of systematic touting by means of agents—a custom, we believe, more common among the lower strata of legal practice than among those of the healing art. Heartily as we oppose these and all kindred methods of advertisement, we cannot but think that the temptation to resort to them is stronger in the case of our younger and poorer medical brethren than of the votaries of the law. We are comparatively straitened, for example, in the matter of remunerative appointments. The greater number of public offices with us are gratuitous. This cannot be said of lawyers. The fees of general practice, again, do not bear nearly the same ratio of emolument to the work done as do the charges of legal procedure. We are, moreover, expected in the name of common humanity to render many services as matter of charity even in our private medical capacity, and to some extent this is unavoidable. Resort to law courts to recover fees is, in the case of medical men, fraught with serious drawbacks, quite apart from the trouble and loss of time which they directly cause, while costs for the lawyer are part of the assignment of every verdict, and the assignment implies neither trouble nor loss of professional dignity. These various circumstances must greatly discount the value of medical work, and intensify the tendency to place considerations of pocket before those of duty and honour. We earnestly press upon all who are subject to such temptations as we have indicated, and first of all upon the younger members of our own body, to rely notwithstanding upon the regular methods of practice, even at the risk of early difficulties, since there is no other road so sure to final professional success and satisfaction.

Annotations.

"Ne quid nimis."

THE M.D. AND M.S. DEGREES OF THE LONDON UNIVERSITY.

At the last meeting of the Senate of the University of London it was resolved, on the recommendation of the Conjoint Committee on Examinations, that "the subjects of Logic and Psychology should be withdrawn from the syllabus of the M.D. and M.S. Examinations, and that in lieu thereof questions should be substituted in Mental Physiology, especially in its relation to Mental Disorder." This formal withdrawal of such an obsolete mental gymnastic as Formal Logic will be so far satisfactory to candidates for the M.D. and M.S. degrees; but the real difficulty has always been to understand what is included in the term "Psychology." It is quite certain that different examiners have given a special significance to the term. We wish very much that "Mental Physiology, especially in its relations to Mental Disorder," were more closely defined, as we foresee the former difficulty arising under the new regulation. The Physiology of the Brain is within the range of the syllabus of the Intermediate M.B.; the treatment of its diseases is included in the Final M.B. Examination. We could have wished that so-called Psychology, which rests on no scientific basis whatever, and is only inferential from beginning to end, had been simply withdrawn, and that no such palpable compromise as the present regulation had been put in its stead; for it must always remain to the candidate that fatal possibility—an unknown quantity.

PUBLIC HEALTH (MEMBERS AND OFFICERS) BILL.

Under Section 193 of the Public Health Act, 1875, it is enacted that officers or servants of local authorities shall not be in any way concerned or interested in any bargain or contract made by those authorities, and this under pain of penalty and at the risk of being held hereafter incapable of holding office. This clause is found to act in certain instances with unnecessary severity, and hence a Bill, which bears the names of Sir John Kennaway, Mr. Long, and Mr. Cowen, has been brought in for the purpose of enabling officers and servants to be interested in contracts with local authorities as to the sale, purchase, leasing, or hiring of lands, rooms, or offices, and also as regards the insertion of advertisements in newspapers in which they are interested, provided the consent of two-thirds of the number of members of the local authority present at a meeting held seven days after a notice stating the nature of the contract has been sent to every member of that authority has been obtained. Another clause makes it unnecessary for any member of an authority to vacate his seat by reason of his having a share or interest in any papers in which advertisements relating to the business of the authority have been inserted. So far as advertisements are concerned, the Bill is unquestionably needed; and as to the other matters referred to, the precautions which will be necessary seem ample to cover any possible irregularities.

METROPOLITAN LOCAL DEATH-RATES.

The disturbing influence of deaths in public institutions causes considerable difficulty in the calculation of trustworthy local death-rates in the metropolis. It is only a year or two since the insertion in the death register of the previous residence in entries relating to deaths in institutions first rendered possible the distribution of these deaths to the sanitary districts to which they belong. The last Weekly Return gives for the first time a table showing the corrected mortality in Registration London and in its thirty-nine sanitary areas. The period embraced by this return is the thirteen weeks ending the 4th inst. It is well known that in most large towns certain numbers of deaths of non-residents are recorded, but it has been held that these deaths are balanced by those of residents recorded outside. The new table given by the Registrar-General corroborates the trustworthiness of this assumption. The result of the correction of the recorded deaths in Registration London is to add 192 deaths of London residents recorded in the metropolitan asylum hospitals situated outside London, and to exclude 281 deaths of non-residents registered inside London. There can be very little doubt that if the deaths in the county lunatic asylums and in the metropolitan asylums for imbeciles at Leavesden, Caterham, and Darenth were also brought into account, the deaths of residents outside would fully balance those of non-residents inside. The corrected death-rate for the whole of London last quarter therefore differs but slightly from the uncorrected rate—it was 21·5 instead of 21·6 per 1000. This correction, however, leaves out of account the disturbing influence of an unknown number of deaths of domestic servants, shop assistants, and other town immigrants, who, when health fails, return to their country homes, where their deaths in many instances are recorded, although undoubtedly due to the effect of town residence. No attempt is made by the Registrar-General to calculate the death-rate in each of the thirty-nine sanitary areas within Registration London. This is probably due to difficulties in the way of satisfactorily estimating the present population of these areas. In the remarks on the table, however, the death-rates during last quarter in the five groups of registration districts are given as 19·4 in the West, 20·4 in the North, 20·8 in the South, 23·8 in the East, and 29·0 in the Central. These variations in the death-rates give useful indications of the principal slum localities of the metropolis. On the assumption that the increase of population since 1881 has been maintained at the same rate that prevailed between 1871 and 1881, it may be calculated that the death-rate in the first quarter of this year ranged from 27 to 31 per 1000 in St. Giles's, Holborn, St. Luke's, St. George's-in-the-East, Stepney, St. Saviour's (Southwark), and St. George's (Southwark). The death-rates from the principal zymotic diseases ranged from 1·52 per 1000 in the West, to 2·49 and 2·95 in the Central and East groups of districts. The rate from scarlet fever, which averaged 0·18 in London, was equal to 0·56 in East London, and was nearly six times as great as in the four other groups. It is also stated that 4 of the 7 deaths from typhus belonged to East London. These statistics call for the earnest consideration, not only of the metropolitan sanitary authorities, but also of all those interested in the health and social condition of the population of London.

"WIND AND WEATHER PERMITTING."

THIS condition, painfully familiar to the last generation of travellers by sea, but almost forgotten since the days of steam-power afloat, ought to be adopted as a general provision by all who are not of the very strongest and healthiest type of humanity, in respect to out-door engagements at this most trying season of the year, more particularly in London and other large cities. A glance at the obituary column in any leading newspaper will suffice to prove that the risks of life, especially to the weakly and the aged, just now are out of all proportion to the apparent natural vicissitudes of the Spring. The truth is, that the changes of *personal* temperature are so sudden and severe that few constitutions can suffer them with impunity. What we mean by personal temperature is this: The atmosphere generally may, as shown by the thermometer, be fairly mild, or at least not remarkably cold, but owing to the strong currents of icy wind which rush through doors and under archways, out of courts and alleys, round corners and across main thoroughfares from side streets, a pedestrian not able to bear being almost instantaneously deprived of a large proportion of his caloric, and endowed with such vigorous powers of heat-production as to be able to compensate for the loss with extraordinary rapidity, must in a walk of very short duration be thoroughly chilled. Take, for example, any ordinary main street in London of some quarter or third of a mile in length. It will probably have fifteen or twenty side streets on each side; so that, unless the wind chance to blow parallel with the main thoroughfare, a person walking through it will encounter, say in twenty minutes, fifteen or twenty blasts of cold air, which will catch him suddenly. Each of these blasts will do two things to him. First, it will rapidly take from his body as much heat as can be abstracted in the period occupied in crossing the side street, which is considerable; and, secondly, it will give an appreciable depressing shock to the nerve centres through the nerves of the skin. These fifteen or twenty successive abstractions of heat and nervous depressions, following each other at intervals of a minute or a little over, will produce an aggregate impression on the vital state—that is, the heat and the energy of the organism together—at the end of the twenty minutes, which cannot fail to be felt by a weakly or susceptible person. There is no time to recover between the attacks. When a man takes his bath in the morning he gets a reaction following the depression of the chill; but if he no sooner got out of one bath than he plunged into another, instead of benefiting his health, the "tubbing" would do him harm. It is far worse for the pedestrian to walk along such a main thoroughfare as we have supposed than it would be for him to walk on a cliff exposed to the steady blow of the same wind. The organism can much more readily accommodate itself to a prolonged low temperature, if it be not a crippling cold, than it can sustain without injury a rapid succession of little chills and shocks. These are like the rain of knock-down blows that exhausts the boxer. He has no time "to get breath" between the attacks of his opponent. We have not exaggerated this matter, and we venture to think it is one which the dwellers in cities, and particularly those who pass the earlier weeks of the season in London, will do wisely to bear in mind. It is often difficult to tell how a "cold" has been "caught"; but this we know too well, that what seem to be very slight colds are often productive of the most serious results. It is not heroic, but rash, to risk taking cold. The most robust and apparently the strongest may succumb to the consequences of such an attack. Healthy and hardy country folk, and even mountaineers who "live in the open," frequently take cold in London or some large city. It is the fusilade of deadly little chills they cannot bear. No one need feel humiliated in taking precaution against the strangely harassing attack which the enemy is wont to make on our vital forces in Spring, and particularly in April and May.

TOLERANCE AND ADVANTAGE OF LARGE DOSES OF POTASSIUM IODIDE.

DR. HUTCHINSON of Chicago, in the New York *Medical Record*, details a case in which he had given large doses of iodide of potassium with a curative effect. The case was one of a woman, aged fifty-four, married for the second time, with three children by the first husband and one by the second, all healthy, and with no history of syphilis. The disease from which she had suffered for twelve years was abscesses on the legs, over the tibia, and on the chest, over the sternum. They were slow and very painful in their course, being months in opening, while months elapsed before the sinuses closed. They left numerous and depressed scars. At the time of consulting Dr. Hutchinson the patient had two ulcers on the forehead, and one *cold* abscess on the arm. Tonics having failed, and there being great pain on pressure over the shins, the patient was put on iodide of potassium, eight grains three times a day, till she took thirty grains three times a day. An average quantity of one drachm a day was taken for four months, with the effect of a cure. Tonics were afterwards given. There is a suspicious suggestion of a specific factor in this case, both in its symptoms and its therapeutics. The iodide was not only well borne, but the patient's appetite improved, and she rapidly regained flesh and strength, as often happens to patients in whom mercury acts curatively.

THE CONVICT BRIGGS.

WE are glad to find that after mature consideration the Home Secretary has advised Her Majesty to remit the remaining portion of the sentence of twenty years passed on the prisoner Briggs. This is only justice; for, as we pointed out in November, 1884, the medical evidence, as reported, was not consistent with the teachings of scientific knowledge; and, apart from this, it has transpired that the prisoner was in all probability physically incapable of *forcibly withholding* food from the deceased. We do not advocate the wholesale remission of punishment; no one will be found more loyal in the support of justice equitably dispensed than ourselves; but the above was evidently an instance for the exercise of the clemency of the Crown. It is to be hoped that Sir W. Harcourt will see his way to investigate, and that early, the case of Dr. Bradley, for if ever a prisoner merited the benefit of the doubt it was the latter.

THE LATE LORD MAYOR.

We learn that the late Lord Mayor had suffered for some years from diabetes. On Easter Monday he caught cold whilst supporting the Mayor of Brighton in his official capacity at the review on Brighton Downs. An attack of pleurisy supervened, but the fatal termination was caused by diabetic coma. Although so well recognised by the profession, it is hardly known beyond it on how fragile a thread a man's life depends when he is suffering from diabetes, even though the disease is not apparently progressive. The amount of sugar excreted may be stationary or even diminishing under medical and dietetic treatment, and yet by the slightest accident the balance may be destroyed and death rapidly result. A few weeks ago a bicycle accident of no very great severity caused the death of a diabetic patient; and here an attack of pleurisy, apparently also of an ordinary character, has determined the death of the Lord Mayor, not from the inflammation, but from diabetic coma. Cases in which the onset of blood-poisoning from a scratch on the hand, and infection by the acute exanthemata, have led to the death of diabetics almost before the diseases have had time to declare themselves are also not uncommon, and show what excessive care is necessary for the preservation of life against accident when a person is suffering from permanent glycosuria.

MICRO-ORGANISMS OF RHINO-SCLEROMA.

The existence of micro-organisms in rhino-scleroma has been denied by Fritsch, Pellizari, Chiari, and others. M. Cornil has examined with M. Alvarez a certain number of specimens of the disease in question, and they have not once failed to find bacteria having a peculiar form, and presenting a well-defined capsule. The bacilli are short rods, having a length of from about two to three thousandths of a millimetre, and about ·4 to ·5 μ in diameter. Spore-like bodies have been seen in the interior of the little rods. The micro-organisms may appear in the form of regular ovoids, of which the periphery is formed by a well-defined capsule. In the centre of this capsule the little rod is seen either as a homogeneous and smooth structure or else formed by two, three, or four round or ovoid granules. A clear line always exists around the bacillus. The capsule is formed of a hard structureless colloid material. The bacteria may unite in pairs by fusion of their capsules. Many of the bacilli were observed to be free in the tissues, being situate between the fibrils of the reticulum, around the large cells, in the spaces of the reticulum, or in the lymphatic vessels of the superficial or deep parts of the skin.

THE WESTMINSTER UNION.

The guardians of the Westminster Union who supported Mr. Bliss, the ex-master of the workhouse, in those irregularities which eventually deprived him of his appointment, undeterred by their rejection last year *en bloc*, again attempted at the last election to regain office. They were, however, rejected by an overwhelming majority of the ratepayers, whose public spirit, in polling so heavily as they did to prevent the return of the old members who on the last occasion of their holding office failed in so marked a degree to justify the trust reposed in them, cannot be too highly commended. At the last meeting of the Board of Guardians previous to the election, the following resolution was passed:—"That the best thanks of the Board be and are hereby accorded to Dr. Joseph Rogers, the medical officer of the workhouse, for the zeal and ability with which he has discharged the duties of his office during the past year, and for the confidence which the guardians have therefore been able to repose in him, and which they trust he will continue to deserve from their successors."

RESECTION OF CLAVICLE FOR SARCOMA.

An interesting surgical case has been placed on record by M. Polaillon. The patient was a girl aged sixteen, in whom a swelling of the outer end of the right clavicle was first noticed eighteen months ago, and had gradually increased in size. There was not much interference with the movements of the arm, and but little pain. The tumour was about the size of the fist, of bony consistence, and lobulated in outline. The skin over it was normal. There were no signs of compression of the brachial nerves or vessels. The lymphatic glands were healthy. Careful examination showed that the tumour did not pass beyond the limits of the expanded clavicle in any direction. The operation was performed on Jan. 29th under the spray. A horseshoe-shaped incision was made through the soft tissues, and the flap turned inwards, its base being at the neck of the patient; the clavicle was cut through at the insertion of the sterno-mastoid in the inner third of the bone, and then disarticulated at its outer extremity. In order to isolate the tumour the fibres of the trapezius and deltoid were cut through at their insertion into the clavicle. Antiseptic dressings were applied. The patient did well, and left the hospital six weeks after the operation. There was but little deformity, and the movements of the arm were perfectly preserved.

POOR-LAW MEDICAL RELIEF IN BIRMINGHAM.

An inquest in the Birmingham coroner's court on the 9th inst. resulted in a verdict of "Death from natural causes," with a rider affirming that the medical officer's conduct was very censurable. The facts lay in a small compass, and were substantially agreed upon. A poor man, aged forty-three, had suffered from bronchitis for three weeks, when, on March 28th, his son, aged fourteen, went to the parish offices and obtained an order from the relieving officer. The surgeon saw the patient the same evening, and several times afterwards, giving orders for medicine, which was duly supplied. But the poor man's circumstances were most wretched. His children having, according to report, deserted him, there was no one to attend to him; there was only a handful of fire in the grate, and some bags of flour did duty for a bed. In this state of things the medical officer strongly, and repeatedly, advised the patient's removal to the parish infirmary; but the advice was unheeded, until Saturday morning, the 4th inst., when deceased's brother called at the medical consulting-room in the parish offices, and obtained an order for removal from the surgeon, who signed it, though it appears he had not seen the patient for two days. The removal was effected with a plentiful supply of blankets, in a car-ambulance, and no one questioned that, on the patient's arrival at the infirmary, every possible attention was paid to him; but he did not survive many hours. The particular case derives special importance, from the exceptional circumstances in which Poor-law medical relief has for some time been administered in Birmingham. The infirmary at the workhouse is, by common consent, well regulated. The staff of resident doctors and nurses is good; cases of exceptional gravity are placed under the care of Dr. C. W. Suckling, one of the honorary physicians to the Queen's Hospital, and his recommendations are very liberally acted upon by the guardians. But the out-door medical relief has for many months been in an unsatisfactory state. An inquiry by the Local Government Board, during the summer of 1884, resulted in the resignation of the four medical officers, who had for several years ministered to the poor in the extensive parish of Birmingham. Projects of reform became the order of the day; but, pending their discussion, temporary medical officers were appointed, subject to a month's notice. Several at least of these gentlemen have done their work in an unimpeachable manner; but the conditions of the permanent appointments are yet undetermined. The delay in effecting the reforms, which everyone admits are urgently called for, is supposed to be due to some differences on administrative details between the Poor-law authorities in London and Birmingham. This is a state of things demanding immediate attention. The present Board of guardians in Birmingham may plead indulgence, as they have only been just appointed. But though that be true collectively, they are individually, for the most part, old guardians. Their chairman has a very large acquaintance with Poor-law medical relief, and the Inspector for the district is one of the ablest and most humane officials in the service. The case seems one for nverting Talleyrand's famous maxim—"Above all, some zeal, gentlemen," and the work may be done soon and well. The cause we plead is no other than that of thousands of sick and helpless poor.

PTOMAINES IN CHOLERA.

AN original article contributed to the *Journal de Pharmacie et de Chimie*, by M. Villiers, gives an account of some investigations on the presence of alkaloids in the tissues of fatal cases of cholera. The tissues studied were the kidneys, intestines, liver, and the blood in the heart. The method of extracting the alkaloid was that of Stas. The alkaloid was obtained in fair quantity from the intestines, some traces were separated from the kidneys, but the liver and blood contained almost none. The alkaloid is liquid, possesses an acrid taste and has the odour of fresh hawthorn. It had the alkaline reaction, and its base could not be displaced by the alkaline bicarbonates. Iodide of mercury and potash causes a white precipitate in its solutions or those of its alts. Iodised iodide of potassium gives a brown precipitate even in very dilute solutions. Bromine water, picric acid, chloride of gold, tannin, and bichloride of mercury give precipitates, but chloride of platinum and bichromate of potassium do not. Pure sulphuric acid develops a slight and fugacious violet colouration. The hydrochlorate of the alkaloid is neutral in reaction, crystallises in long fine needles, and is extremely deliquescent. The physiological effects in frogs were ill defined; in guinea-pigs very marked, and consisted of remarkable periodic variations in the frequency of the cardiac pulsations; the anterior limbs were remarkably convulsed three-quarters of an hour after the njection, and afterwards the posterior limbs were affected n a similar manner; the convulsions passed away, and the animal remained ill and died in four days. After death here were found subpleural ecchymoses; the heart was dilated and full of liquid blood; the brain was a little congested. M. Villiers believes that the alkaloid is formed in the intestines and excreted by the kidneys.

THE CHELTENHAM APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

WE have received several communications relating to the recent proceedings for the appointment of medical officer of health for the Borough of Cheltenham; and one which has just reached us from a disappointed candidate, and which is supplemented by accounts of the proceedings of the Town Council, places the whole matter before us. The election was to be made subject to the Order of the Local Government Board, which body requires that, unless it shall specially so decide, the candidate chosen shall be a fully qualified medical practitioner. The Cheltenham appointment had been held by a distinguished physician, and some thirty-five candidates sought to occupy the position which had been so ably filled by the late Dr. Wright, F.R.S. The candidates included practitioners of high and recognised standing, and men of scientific training, some of whom possessed certificates in hygiene: but amongst them was one who had a single qualification only, and he, though apparently a resident in Cheltenham, is stated not even to have been known to some of the medical profession of the town. This one candidate, therefore, failed to comply with the terms on which the advertisement declared that the appointment was to be made. But instead of his name being at once erased on the ground that he was disqualified, the corporation literally passed by all the qualified candidates and elected the only disqualified one amongst them. Then came the question as to the legality of his election on the ground of his possessing a single qualification only; but before this could be dealt with the candidate in question goes somewhere or other, and comes back within a few days fully fledged in so far as qualification is concerned. Now, the corporation submit that the man of their choice fully complies with the terms of the Order of the Local Government Board, and, according to an answer given by the Parliamentary Secretary of the Local Government Board in the House of Commons, this view is likely to be accepted by the Board. But another question is now being raised in the Town Council itself. Even if the Local Government Board choose to accept a qualification obtained after the election, and one the value of which can best be judged of by the circumstances under which it is procured, yet it is by no means clear that an election made subject to an advertisement which called for a duly qualified practitioner can be valid when the choice of the electing body falls upon a candidate who is not duly qualified, and this in the presence of a number of duly qualified candidates who had presented themselves for election. Mr. Onley, a member of the Town Council, has raised this point, and some at least of the rejected candidates intend to do the same. The question is one of extreme importance, for the Cheltenham election will form a precedent which is not likely to be forgotten, and we should like in the first instance to see it brought under the notice of the President of the Board, with a view of eliciting his official opinion on the subject. When that has been procured, the thirty-four duly qualified candidates who were passed by will know precisely how they stand with regard to future action.

HEREDITY AND TUMOURS OF THE EYE.

IN the *Revista Argentina de Ciencias Médicas*, a Buenos Ayres periodical, the typography and general "get up" of which we feel bound to say puts to shame most of the European medical monthlies, Dr. Juan Alba Carreras describes a case of cellular sarcoma of the choroid in a girl aged three years. An enormous eye protruded from the orbit, hard as an ivory ball, the pupil reaching to the edge of the cornea. The ocular conjunctiva was covered with numerous tortuous vessels, indicating great obstruction to circulation. The lens was quite opaque, and of a yellowish colour. There were severe shooting pains on the side of the head. After enucleation, a sarcoma of the choroid was found, of the size of a walnut, which had ruptured the sclerotic near the optic nerve, the sheath of which was two centimetres in thickness, and, instead of nervous tissue, contained only a white granular substance. The patient, though treated with antiseptic precautions, died of meningitis on the seventh day. As the question of the influence of heredity on ocular tumours had been raised, the relatives were examined. The father had a double external strabismus, caused by a coloboma of triangular shape, situated on the inferior and external aspect of each eye. In the brother, aged seven, was found in the left eye a dilated insensitive pupil and a detached retina, with complete loss of vision; the right eye being normal.

with the exception of some increase of tension. This child had received a blow in the left orbital region two months before, and for the last fortnight the parents had noticed that the fundus appeared white. The diagnosis was that a similar tumour existed to that from which the sister had suffered, and immediate enucleation was advised, which was refused, as, indeed, it had been when the other child was first seen. The conclusions drawn from this case are: 1. That predisposition to ocular tumours may be inherited, though in this instance the father's eyes have, up to the present time, shown no signs of malignant growth. 2. That coloboma in parents may serve to assist the diagnosis of a tumour in the fundus. 3. That there are conditions which serve to distinguish these tumours. 4. That it is necessary to insist on enucleation as soon as the existence of a tumour is recognised. If this had been permitted in this case, the extensive propagation along the optic nerve, which here existed, and which was doubtless the cause of death, would not have taken place.

VETERINARIANS AND FOOD INSPECTION.

THE veterinary surgeons of the province of Cordova having complained to the Spanish Royal Council of Health that the local authorities had appointed as inspectors of food two medical men, instead of members of their own body, whom they considered best fitted for such duties, the Royal Council replied that there was no doubt that veterinarians ought to be appointed to inspect meat, but that there was no law, and not even a uniformity of custom, concerning the appointment of inspectors of other articles of food. It was, however, a subject which ought to be settled, and therefore the Council resolved to advise the Government to make the following regulations:—(1) That the inspection of warm-blooded animals, alive or dead, fresh or preserved, should be exclusively in the hands of veterinarians; (2) that the inspection of all other articles of food sold in markets, including cold-blooded animals, should be committed indiscriminately to medical men or to pharmacists; (3) that both classes of inspectors be irremovable from their posts, except for grave cause. The Royal assent was given to the above-mentioned recommendations, which have just appeared in the *Official Gazette.*

AN ORTHOPÆDIC MARCH PAST.

GREATER triumphs than the artificial legs and arms invented by the Count de Beaufort civilisation has few to boast of. These limbs, at once thoroughly efficient and comparatively inexpensive, have been judiciously doled out by the "Assistance aux Mutilés pauvres," of which the Count is secretary, till not in Paris only, but throughout France, the soldier who in war, or the artisan who in work, has lost either extremity or both might now be mustered in their thousands to attest the blessings vouchsafed them by the rehabilitating invention. From France the charity has been extended to Italy, thanks to General H. H. Maxwell, C.B., R.A., who, wintering in Rome or *en route* through the Italian provinces, has now these six years been conferring the Beaufort limb on "deserving objects" with signal success. His experience, embodied in six reports addressed to those subscribing to the charity, has fairly and fully established the following:—1st, that the Beaufort leg, with its curved, solid, false foot, with which a man can walk like a carter for sixteen miles a day, is vastly more useful than any mere "peg-leg"; and, 2nd, that in many cases a Beaufort hand, with the fingers stiff and a spring thumb, is more serviceable than a mere hook, enabling its possessor to perform good penmanship, to pick up anything seizable, to hold knife and fork, to play chess, and, indeed, to do all the work of many a natural hand. Like all charities, that of the "Legs and Arms" must, however, be administered with circumspection. To quote the General (whose reports, by-the-way, always racy in style, are often romantic in interest):—"Giving a penny to a beggar, a shilling to a poor-box, or a cheque to a society are forms of charity which everyone more or less practises. Strong doubts, however, are apt to assail you at times as to whether you have done your alms in the most judicious way. You may have done right, and, with equal uncertainty, you may have done wrong. This state of mind paralyses your will to pull out your purse. But if you find a man with a wooden pin-leg sitting down breaking stones by the roadside; if the railway navvy or station porter has had his foot amputated, and you find him in hospital thinking of how he is to earn bread for himself and perhaps his wife and children; if, again, alongside of him there is a workman who has lost his hand, crushed by machinery or shattered by explosion,—in all such cases there is no reason for hesitation. You *must* be right in taking out pencil and paper and making notes of the case if you have time to spare; if not, in giving the sufferer your card. If you have not the necessary money yourself, it is to be had for the asking of others who are more fortunate." The General's practice has been to get the man into his own house after he has been completely cured and his stump and limbs have recovered their normal size, to measure him according to Count Beaufort's directions, which he reprints at the end of his first report, and to send these measurements to M. Werber of Paris (orthopædist to the "Assistance aux Mutilés pauvres"), who will promptly and for a very small sum confer on the amputated sufferer the means of earning his bread. What M. Werber has done so well is now equally performed by our own "Provident Surgical Appliance Society for the Relief of the Crippled Poor," which also takes orders for the Beaufort limb; while other great centres of population, not less than Paris, Rome, and London, will ere long be equipped with similarly appointed charities. In a country like Italy, where mendicancy has become an "institution," if not indeed one of the fine arts, General Maxwell's movement bids fair to fructify most beneficially; and in the files of rehabilitated and breadwinning cripples mobilised in his successive reports we congratulate him on a peculiarly efficient, not to say touching, "march past."

IRREGULAR PRACTICE IN CAPE COLONY.

THE great problem of ignorant and illegal practice is greater in remote and ill-provided districts than in settled countries and large towns. There are parts of Norway where people live thirty miles from the nearest surgeon. It must be still worse in many other countries, where educated advice and proper medicines are a luxury of the rich, and the great epochs of sickness and labour, and, even the great event of death, have to be faced without the assistance or the amenities of medicine. Worse than the mere absence of medical ministration occurs in such countries. The quack and the pretender take the place of, and assume more than the airs of, the regular practitioner, and often gravely add to the danger of the disease. A case in point is before us. At the Uitenhage Circuit Court (Cape Colony), Adolph Frankenburg has been tried for culpable homicide, or for contravention of the medical ordinance. The facts are that he, having no legal authorisation to practise, administered medicines to Joseph Blommetje of Vervolf, a strong, hearty man, suffering from erysipelas, and that he introduced into the eye certain highly irritating drops, after which the "apple of the eye dropped out," and the patient languished and died. Dr. Arthur Vanes was of opinion that the patient's death was caused by the treatment. The prisoner had been previously convicted. The judge, finding him guilty on the second count, inflicted a fine of £50, and was especially severe on the accused for venturing to treat so delicate an organ as the eye. Like other irregular practitioners, he took large fees from his dupes, to whom of course he promised a cure. The hardship is that at the Cape, as elsewhere, the chief odium of exposing the mischief worked by such characters as Frankenburg devolves on the medical practitioner who is called to see the victims. No good will be done till the law devolves on some public officer the duty of punishing illegal and ignorant practice.

MERCURIC CHLORIDE AS A DISINFECTANT.

DR. GEORGE M. STERNBERG, in his recent reports to the American Public Health Association, confirms the opinion arrived at of late years in more than one quarter as to the very powerful antiseptic action of perchloride of mercury. He relates experiments in proof of the inhibiting action of very dilute solutions upon the development of the bacilli of anthrax and other micro-organisms, and sums up his conclusions thus:—

"Mercuric chloride, in aqueous solution, in the proportion of 1 in 10,000, is a reliable agent for the destruction of micrococci and bacilli in active growth not containing spores; and in the proportion of 1 in 1000 it destroys the spores of bacilli, provided that the micro-organisms to be destroyed are fairly exposed to its action for a sufficient length of time. A standard solution of 1 in 1000 may be safely recommended for the disinfection of bedding and clothing which can be washed, for washing the floors and walls of infected apartments, for disinfecting the hands and instruments of surgeons and gynæcologists, and as a disinfecting wash for superficial wounds or mucous surfaces. For continuous application to wounds, &c., a solution of 1 in 10,000, or less, should be effective. A standard solution of 1 in 500, with the same quantity of potassium permanganate, may be safely recommended for the disinfection of liquid fæcal discharges, and other fluid material supposed to contain 'disease germs,' provided the time of exposure is not less than two hours, and the quantity of material to be disinfected is not in excess of that of the standard solution used."

WEST INDIAN FEVERS.

DR. A. W. REYES of Havana has published a pamphlet giving an account of the graver West Indian fevers, in which he says that owing to unusually severe meteorological conditions—intense heat followed by rain—fatal malarial fevers were very numerous last year. He advises medical men, when rain comes after great heat, to prepare for a treacherous and destructive enemy, and in general to treat all fevers with quinine; and he recommends mothers of families to be on the look-out for the first signs of fever and to call for medical aid immediately, suggesting that if they will "provide themselves with thermometers (for the detection of incipient fever), they will save many professional honoraria—and some tears."

PNEUMONIA IN NEW YORK.

A SUMMARY of 252 cases of lobar pneumonia is given in the form of a paper in the *Medical Record* for March 28th, by Dr. Edwin T. Doubleday, registrar of the New York Hospital, which was opened in 1877. In the earlier years the histories were not complete. The decades in which the largest number of cases occurred were from the ages of twenty to thirty, 70 males and 18 females; thirty to forty, 47 males and 13 females. In 150 cases there was no assignable exciting cause; in 47 cases there was exposure to wet and cold. There was an acknowledged alcoholic history in almost 50 per cent. of the cases, and where the history was marked the death-rate was 68 per cent. The complication most frequently noticed was pleurisy. The mortality was great. In the complicated cases, 85 died and 49 recovered; in uncomplicated, 33 died and 81 recovered. This high mortality is attributed by the author to the large number of complicated cases; the large number of those past treatment and moribund on admission to hospital; the patients being alcoholics as a rule; and the late day of admission, the fifth day of the disease. The remedies used were aconite (in a few cases) and quinine (extensively); when the case was seen before consolidation a dose of calomel (five to ten grains) was frequently given. For delirium, a very sparing use was made of bromides, chloral, and morphia. For heart failure, ammonia and tincture of digitalis (five to twenty minims) every three hours, with alcohol, were employed. Alcohol, in the form of whisky, was given early. Lately antipyrin had been given in 12 cases with the effect of reducing the temperature from 1° to 3°, and causing slight sweating and slight cardiac depression. The individual remedies, excepting perhaps the calomel, are not open to much criticism; but the result is certainly not satisfactory, and contrasts very unfavourably with the result in Dr. F. Hughes Bennett's series of cases to which we referred last week.

EXPERIMENTAL EPILEPSY.

A COMMUNICATION has been made by M. Vulpian to the Académie des Sciences on the results of excitation of the white matter in the neighbourhood of the sigmoid gyrus. He asserts that the convulsions of epilepsy are manifested not only in the voluntary muscles, but also in those of organic life, as witnessed in the modification of the secretions, the dilatation of the pupils, and the like. He has sought to determine the influence of excitations of the cerebral white matter on the secretion of bile, pancreatic juice, and urine. Cannulæ were placed in the bile-duct, pancreatic duct, and ureters of the animals employed. Electrical stimulation was employed. The secretion of bile was found to be augmented; that of the pancreas was not influenced either way; that of the kidney was arrested. By curarising a dog and keeping up artificial respiration he has determined that excitations of the surface of the gyrus in question gave rise to a genuine attack of epilepsy of the involuntary muscular tissue. M. Vulpian believes that the last-mentioned experiment has not hitherto been carried out.

HONEST CRITICISM.

WE congratulate our contemporary, the *Grocers' Gazette*, on having vindicated the undoubted right of the press to point out tricks of trade which are injurious to the health of the public. If it were not permissible to put the community on its guard against adulteration and the selling of impure or bad goods as fit for use and of excellent quality, it would be useless to touch the subject of sound and unsound food at all. It seems strange that any manufacturer should have had the temerity to go before a court with so poor a plea as that urged against the *Grocers' Gazette*. Simple justice has been done, and the public interests have been secured. Our contemporary has done good service.

THE PIGMENTARY SYPHILIDE.

IN the April number of the *Monthly Journal of Cutaneous and Venereal Diseases* an excellent chromolithograph illustrates a brief original article by Dr. R. W. Taylor on the Pigmentary Syphilide. Many authorities, both at home and abroad, now recognise the existence of a certain chromatogenous affection peculiar to syphilis, which is variously designated the pigmentary syphilide and syphilitic leucoderma. Dr. Taylor comes to the conclusion that syphilis frequently causes a deep cutaneous pigmentation, which occurs in spots without any affection of the skin between the maculæ; he believes, also, that syphilis may cause pigmentation and leucoderma in the same case, as well as an abnormal distribution in the amount of pigment normally present in a given area of skin, so that there is a preponderance of the leucodermatous changes as compared with the pigmented maculæ.

"SIMULO" IN EPILEPSY.

IN the *Boletin Médico*, published at Trujello, Peru, Dr. Larrea y Quezada describes the treatment of his own case of epilepsy, when a boy of thirteen, by simulo, which is the fruit of a plant of the hyssop family—Capparis coriacea. The dose was forty-five grammes of the powder in wine night and morning. Though he had suffered from fourteen attacks, preceded by a distinct aura, his cure was immediate and complete. Since he has been in practice he has employed the drug in all cases of epilepsy, and also in nervous and hysterical cases, with the best results.

A CORRESPONDENT has written to us calling attention to the condition of the Salvation Army in the barracks at Clapton. He states that small-pox is now, and has for some time past been, very prevalent among the persons resident in the building; in fact, lately, scarce a day has passed without some patient being removed, and yet these people are allowed to hold meetings and to march through the streets, to say nothing of their going into the homes of the poor in the neighbourhood. If our correspondent's statements are correct—and we have no cause to doubt them,—the proceedings of the Clapton Salvationists, as a means of spreading small-pox, should engage the attention of the medical officer of health.

WHILST recently partaking of luncheon in a restaurant at Portsmouth, Retired Staff Surgeon Augustus Slight, R.N., died apparently in a fit. A post-mortem examination showed that the deceased, who was seventy years of age, had been suffocated by a piece of meat which was lodged in the throat. The inquest was held on the 9th inst., when the jury returned a verdict of accidental death. The deceased was assistant-surgeon of the *Wasp* at the storming of Sidon and the bombardment of St. Jean d'Acre in 1840, for which he was awarded the medal.

A MADRID medical journal of April 8th says:—"In Jativa the cases of 'suspicious disease' continue. This is a modern denomination for diseases which we are not able to classify, and for which a special column should be opened in our health bulletins. Up to the 6th inst. the official statement is as follows:—'Suspicious diseases (?) attacked, 6; cured, 4; died, 7; still on the sick list, 25. Of these 25, 8 are seriously ill, 2 are getting better, and 15 are convalescent.'"

THE member of the Rochester Town Council who recently stated that he believed there were nearly sixty cases of small-pox in Gillingham has written to the Gillingham Board of Health, saying that he had found he had overstated the total, and that he regretted having done so; but the statement was not made in public or at a council meeting, but in committee, and was not intended to appear in the newspapers.

THE prize for the best essay on the Prevention of Blindness, offered by the English Society for the Prevention of Blindness, has been awarded to a German physician, Dr. Fusch.

DR. and MADAME BRACHET have had the honour of being presented to the Queen during her Majesty's visit to Aix-les-Bains; and Madame Berthier, widow of the late Dr. Berthier, who attended Princess Beatrice during her stay at Aix two years ago, has had the honour of being received by her Royal Highness.

THE statement that small-pox had attacked the inhabitants and employés of the Japanese Village at Albert-gate has been contradicted by an inspector sent to inspect the building by the Local Government Board and by the Sanitary Committee of the Board of Works for the Westminster district.

A TELEGRAM from Marseilles to the Paris *Temps* states that orders have been given to the French authorities to impose three days' quarantine on all arrivals from Spain, on account of the suspicious disease prevalent in some parts of that country.

SIR ROBERT LOYD-LINDSAY, chairman of the National Society for Aid to the Sick and Wounded in War, has received from Mr. Kennett Barrington, its Commissioner at Suakim, a highly satisfactory account of the work done by the representatives of the Society in Egypt.

THE Academy of Medicine of Lima, Peru, is endeavouring to organise chemical and physiological laboratories and an anatomical and pathological museum. At present an especial study is being made on several important questions relating to prophylaxis and hygiene in infancy.

Pharmacology and Therapeutics.

BROMIDE OF ZINC.

THE following conclusions have been arrived at by M. Testa. Bromide of zinc in small doses diminishes sensation; in large doses it diminishes motility; finally, it may cause complete sensory and motor paralysis. The motor and sensory disorders may gradually pass away if the dose given be not too large. Bromide of zinc stops the frog's heart in diastole, but this effect takes some time to appear; its action is more like zinc than bromide of potassium, since zinc disorders sensation first and motion later, whilst bromide of potassium affects both sensation and motion at the same time, though the latter more than the former. Zinc in the bromide ought certainly to be modified in its action by the presence of bromine, and in mammals a certain degree of somnolence was observed. Bromide of zinc acts first on the peripheral terminations of the sensory nerves, and afterwards on the spinal centres, without, however, passing over the nerve trunks. An effect on the cerebrum cannot be denied seeing that somnolence has been observed after the administration of the drug, but the disorders of sensation and motion are independent of its cerebral effect.

BOLDO AND BOLDINE.

Boldo, either as an infusion or extract, which grows in Bolivia, has been employed for a long time in diseases of the liver. The essence and tincture were experimentally investigated by MM. Dujardin-Beaumetz and Vernes in 1874; diuresis and somnolence were the chief effects observed in animals. Boldine appears to be a glucoside, and is extracted from the leaves of boldo; it is obtained as a concentrated solution of an orange-yellow colour, and has an aromatic odour. In animals—guinea-pigs, dogs, rabbits—boldine given by the stomach, under the skin, or into the veins, causes marked drowsiness, which lasts a variable time, and passes into a condition of apparent death. A fatal dose causes death without exhibiting any reaction, and without convulsions. The fatal dose is ·2 centigramme per kilogramme of body weight. In physiological doses the induced sleep passes away without causing any disagreeable effects. In frogs, injections of boldine induce loss of sensation, and the instillation of some drops of boldine into the eye causes insensibility of the cornea like that produced by cocaine. The hypnotic action of boldine is exerted through the intermediation of the cerebral centres, for the somnolence does not appear if the brain be removed or the bulb be divided. In man, boldine administered to the extent of five or six grammes in divided doses has twice been followed by calm and profound sleep. M. Laborde is the author of these new experiments.

COLCHICINE.

M. Laborde has restudied the physiological effects of colchicine. In animals the subcutaneous injection of colchicine into a leg produces at first paralysis of the limb. The general symptoms observed were disorders of the circulation and respiration; digestive disturbances in the form of vomiting of food, next of bile, and finally of blood, were observed; diarrhœa, both of fetid and bloody stools, may occur, whereby a dog may lose a kilogramme of its body weight in the course of a few hours. Death may supervene *as the result of paralysis of respiration. A dose of forty* centigrammes given to a man caused a feeling of oppression at the epigastrium, violent headache, vomiting, diarrhœa, and fainting. A dose of from five milligrammes to one centigramme gave rise to nausea, some vomiting, and a little diarrhœa; the salivary and urinary secretions were also augmented.

THE ACTIVE PRINCIPLE OF SENNA LEAVES.

A paper which has been published in full in the *Pharmaceutical Journal* gives an account of some original investigations made by Dr. Ralph Stockman on the cathartic principle contained in senna leaves. The cathartic acid was separated after a good deal of trouble by means of baryta. The separated principle was proved to be a powerful cathartic by experiments on rabbits. Experiments made by injecting the cathartic acid, which has been proved by Dr. Stockman to be a coloured glucoside, into the subcutaneous tissues and jugular vein of rabbits, appear to show that the principle cannot cause purgation when introduced into the circulation. Very large doses were thus administered, and the animal simply appeared to be out of sorts for a few days, probably as the result of the operation. In all these cases the urine gave the caustic potash reaction, showing that the cathartic acid had been decomposed in the blood.

DETECTION OF ALKALOIDS.

The graphic method now so extensively adopted by physiologists working at the action of drugs on the heart has been used by M. Laborde in some researches on alkaloids. He states that a twentieth of a milligramme of aconitine in the blood suffices to give a graphic tracing of the beats of the heart which is absolutely characteristic of the action of aconitine. In a dog dead from the ingestion of a substance of doubtful nature, veratrine or aconitine, for example, if an extract of the vomited matters be injected into the system of an animal the heart gives tracings which M. Laborde asserts may be correctly assigned to this or that alkaloid.

THALLINE.

According to MM. Brouardel and Loye, thalline diminishes the respiratory capacity of the blood by destroying its hæmoglobin. Its action is said in this respect to resemble that of kairin and to differ from that of antipyrin, which, according to Henocque, has no deleterious influence on hæmoglobin. MM. Laborde and Rabuteau consider that the physiological effects of the different antipyretics cannot be regarded as properly worked out because of the variable chemical composition. M. Henocque states that his results with antipyretics have been uniform and characteristic, so that if the antipyrin be impure, the impurity is always of the same nature.

SULPHATE OF CINCHONAMINE.

Cinchonamine is an alkaloid found by M. Arnaud in the Remigia Purshiana (rubiaceæ), which is indigenous in Brazil. MM. Sée and Bochefontaine have investigated the physiological action of the soluble sulphate of cinchonamine on frogs, guinea-pigs, and dogs. The chief effects observed were progressive enfeeblement of the physiological functions of the central nervous system, convulsive phenomena, and weakening and slowing of the heart's action. Large doses cause rapid death by arrest of the heart in diastole, in frogs as well as mammals. Atropine is powerless to restore the movements of the heart after they have been stopped by cinchonamine. The toxic effects of the sulphate of cinchonamine are about six times greater than that of quinine, cinchonidine, and cinchonine.

BENZOLE IN RODENT ULCER.

The application of pure benzole to rodent ulcers is recommended, and has been practised, by Dr. Sherwell of New York. It does not cause pain, but destroys the sensibility of the parts, giving them a blanched appearance and causing a kind of mummification. After a time a scab is formed, which should be removed and more benzole applied. He suggests also the employment of benzole in cases of cancer of the os uteri, but it may be doubted whether its application to this site would prove efficacious.

PARALDEHYDE.

Dr. T. Suñol states in the *Independencia Médica* that he has used paraldehyde hypodermically in doses of half a drachm to one drachm in bronchitis, tuberculosis, jaundice, typhoid, rheumatism, gastritis, heart diseases, pleurisy, neuralgia, and alcoholic delirium, generally inducing a sleep of from two to six hours, a sleep calm and untroubled, and not followed by headache on awakening. He has only observed excitement in febrile patients. As it does not affect the beats of the heart, it is better than chloral in cardiac cases with much debility, and especially where there is fatty degeneration.

SYNTHESIS OF CONIINE (?).

The *Pharmaceutical Journal* states that M. de Coninck has synthetically prepared a liquid alkaloid isomeric with coniine. Six atoms of hydrogen were introduced into the molecule of β-collidine derived from the decomposition of cinchonine. This artificial alkaloid has been named "isocicutine;" M. Bochefontaine asserts that its physiological properties are like those of the alkaloid obtained from hemlock.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

THE Association of Members of the Royal College of Surgeons has recently forwarded a circular to each member of the College, in which is contained a brief account of the work done by the Association during the first year of its existence for the purpose of obtaining certain reforms in the projected new Charter of the College. After detailing the proceedings taken up to the time the requests of the Association were laid in writing before the Council of the College, the two main points in the requisition being (1) that Fellows and Members shall elect an equal number of representatives to constitute the Council, and (2) that in addition to a poll election at the College, voting by voting papers, to be sent to all Fellows and Members resident in the United Kingdom, shall be allowed, the committee of the Members' Association state that the Association of Fellows appear somewhat liberal in their views; they have proposed, amongst other things, that there shall be an annual general meeting of Fellows and Members, at which the annual report of the Council shall be presented, discussed, and, if approved, adopted; also that no alteration in the constitution and relations of the College shall be effected without the consent of the Fellows and Members, specially convened to discuss such alterations; and that on receipt of a requisition signed by thirty Fellows or Members the president shall convene a general meeting. These proposals, with the addition of representation of Members and election by voting papers, embrace nearly the whole of the preliminary question as far as the Members are concerned; but whether the Council will accede to the requisition is doubtful unless great pressure be brought to bear upon them, and the committee consequently conclude by urging all members of the College who have not already done so to join the Association, in this manner establishing a powerful and influential Association for the protection of the interests of the medical practitioner.

AT the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on the 14th inst., Sir N. W. E. Smart, K.C.B., M.D., Inspector General, in the chair, the sum of £67 was distributed among the several applicants.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.[1]

Typhoid Fever at York, by Dr. Airy.—The medical officer of health for the city of York reported last autumn an outbreak of enteric fever which had already caused 27 deaths. The cause did not appear to lie in the drinking-water nor in the milk-supply, but, according to his view, was dependent in some way on the condition of the subsoil water. Some obscurity, however, attached to the circumstances of the prevalence. Mr. North had made some lengthened investigation into the subject, and he found that from January to the middle of November there had been 315 attacks with 50 deaths, thus giving a high rate of mortality. The total population of York, according to the last census, was 49,530. According to Dr. Airy, York is divided into three registration sub-districts—Bootham, Micklegate, and Walmgate,—and the annual average "fever" death-rates for the ten years ending 1883 were 2·8 per 10,000 for Bootham and for Micklegate, and 3·8 for Walmgate. Fever has also fluctuated in the city; it was specially prevalent in 1875 and in 1881, whereas 1877 was distinguished for its comparative absence. The mortality had been at its height during the autumn months, culminating in October, and thus corresponding with general experience throughout the country at large. York, then, may be regarded as being habitually liable to fever in an endemic form, and this especially in the Walmgate district; and also to epidemic prevalences at occasional intervals. Dr. Airy then proceeds to describe in detail the physical circumstances affecting these three districts severally, to point out in what respects they differ, and to indicate the various localisations of the fever in the different portions of the several districts referred to. He next proceeds to discuss such questions as the water-supply, milk-supply, &c. The water-supply cannot be regarded as a satisfactory one, it being derived from the Ouse at a point below which it receives the drainage of many villages and much agricultural and other land. It is also dammed up below York by means of a weir and lock, and hence during periods of drought such as occurred last year any pollution might become concentrated and lead especially to affect the source near the intake. Dr. Airy is, however, inclined to think that at all times during the year the flow in the river was sufficient to enable him to eliminate the special source of danger which the backing up of sewage would have caused. Then, again, the water-supply being the same for the whole of the city, any injurious property it possessed would presumably affect the whole city impartially, whereas, as a matter of fact, the incidence of the fever was markedly upon three separate spots in the city. Local water pollutions in the mains or otherwise might have occasioned this special incidence; but after all the conditions likely to have led to any such occurrence had been thoroughly sifted, no ground could be found for any suspicion of the kind. Milk and other beverages as a cause of the disease had also to be set aside. Coming next to privies, &c., it would appear that York is not favourably placed, and there seemed no doubt but that infection had been spread by means of faulty structures; but the actual cause of the epidemic did not lie here. A good deal of attention has also been paid in York to disconnecting house drains, especially in the poorer parts of the city, and such connexions are hence eliminated as a cause of disease. The sewers were laid in 1854-56; they have their outfalls below the summer level of the Ouse; they have no intentional means of ventilation, and there is hardly any provision for their systematic flushing. The only means of relief from pent-up foul air which they have lies in untrapped street gullies, rain pipes directly connected with the sewers, and defectively trapped house connexions. Frequent complaint is made of the habitual sewer stink, and, according to Dr. Airy, York is from this cause in a state of chronic infection that probably accounts for its habitual fever prevalence. As one sewer chances to be more impregnated with infection than another, so one region or another would suffer most, and the specially foul conditions connected with the Foss sewer appeared fully to explain the habitual incidence of fever upon the Walmgate district. So much for the general fever prevalence in York. As to 1884, it deserves notice that the fever mortality for the third quarter of that year in the whole of the East Riding was more than double the average of that for the preceding five years. The summer was remarkably warm, the rainfall was much below the average, and so accumulation of sewage in drains and sewers would be specially favoured, and the offensiveness at certain outfalls is well remembered by many inhabitants of the city. Indeed, Dr. Airy is of opinion that throughout August there was a ripening of conditions exceptionally favourable to the development of typhoid poison in the York sewers, and he inclines to the view that such a gradual ripening must, sooner or later, have culminated in an outbreak of fever, even without the occurrence of any signal event that could be recognised as the determining cause. As to the ground air, it is highly probable that the special conditions of the autumn of 1884 may have led to the expulsion from the soil, by means of a rise in the subsoil water and otherwise, of foul air, and that such occurrences may materially have aided in the special prevalence from which York has suffered. The drawing-off of the Foss water and its subsequent rise had doubtless an influence in this direction; but such influences were probably local only, and would hardly account for the simultaneous outbreaks such as occurred in some large districts. How far meteorological conditions may have aided in this result is uncertain—we know too little about their influence to judge; but there was very little change of atmospheric pressure in the month of August. The report is an interesting one, and well deserves study. We are glad that it is one of those which have been placed on sale.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kettering Urban District.—This town has in recent years effected substantial sanitary improvements, and during the past eight years there have been only five deaths from enteric fever in a population now reaching some 14,250. Last year there was but little infectious disease of any sort. The deaths under one year of age are, however, unsatisfactorily high. Last year they amounted to nearly 18 for every 100 births, a rate which is excessive. Mr. Dryland attributes it mainly to ill-feeding, soothing syrups, and neglect, conditions which are all but invariable in towns where female labour is employed. Some diarrhœa was brought about by the extreme drought, which caused a scarcity in the public water-supply, and in the effort to remedy this the supply became so muddy that people resorted again to old disused wells. Common lodging-houses and slaughter-houses are well looked after, the bakehouses are inspected with regularity, the system of public sewerage is being added to and perfected, vaccination is efficiently performed, and sanitary work in general would appear to be carried out under a system of regular supervision.

Chester-le-Street (Rural).—The Rural Sanitary Authority of Chester-le-Street has divided their district for public health purposes into two parts, each of which is co-extensive with a registration sub-district. The report for Chester-le-Street sub-district shows that during 1884 the death-rate from all causes was comparatively low, although both the mortality from zymotic diseases and the death-rate of children were excessive. Dr. Morris estimates the population of his district in the middle of 1884 at 24,500, but he omits to state on what basis the estimate is calculated. Based upon the rate of increase that prevailed between 1871 and 1881, the estimate would be considerably more; and judged by the birth-rate, which is given as 43·3, it would appear certain that the present population is not over-estimated. The death-rate last year was 19·3, slightly below the rate in the whole of England and Wales, and 1 per 1000 below the mean rate in the county of Durham. The deaths from the principal zymotic diseases were 69, which included 26 from scarlet fever (so constantly fatal in mining populations), 23 from diarrhœa, 9 from typhoid fever, and 2 from small-pox. These 69 deaths were equal to a rate of 2·9 per 1000. With regard to child mortality, it is stated that of the 472 deaths in the year, 241, or 51·1 per cent., were of children under five years of age, an undoubtedly excessive proportion, but giving no real clue to the true rate of child mortality, which can only be calculated upon the number of children living at the same ages. Infant mortality—that is, the deaths of infants under one year—was equal to 15·8 per cent. of the births registered, showing a marked excess. Dr. Morris appears to have debited the whole of the deaths in the union workhouse to his sub-district; if this be the case, it is an obvious oversight. Twenty-six cases of small-pox were reported in the district, but only two deaths were referred to this disease, and with regard to one of those cases the medical officer is "disposed to think that the cause of death was malignant scarlet fever." The authority, which has not yet seen the necessity to provide any hospital accommodation for infectious diseases, is to be congratulated at having at present escaped an epidemic outbreak of the disease. It is, however, impossible to say how many of the 26 deaths from scarlet fever might have been avoided if such accommodation had existed. It appears from the report that 67, or 13·7 per cent., of the deaths during the year were uncertified, in most cases because the deceased persons had been attended by unqualified, or at any rate unregistered, medical practitioners. One of these uncertified deaths was attributed to typhus; and with regard to this case the medical officer satisfied himself that, "whatever was the cause of death, it certainly was not typhus." Such a state of things is as bad for our national mortality statistics as it is for the public.

---

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5804 births and 4271 deaths were registered during the week ending the 11th inst. The annual death-rate in these towns, which had been equal to 23·5, 23·2, and 23·1 per 1000 in the preceding three weeks, rose last week to 25·0, and exceeded the rate in any previous week of this year. During last quarter the death-rate in these towns averaged 21·9 per 1000, and was 2·3 below the mean rate in the corresponding periods of the nine years 1876–84. The lowest rates in these towns last week were 20·0 in Brighton, 20·5 in Leeds, 20·9 in Derby, and 21·2 in Norwich. The rates in the other towns ranged upwards to 33·8 in Preston, 35·8 in Huddersfield, 36·0 in Manchester, and 41·9 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased from 377 to 465 in the preceding six weeks, further rose to 478 last week; they included 164 from measles, 127 from whooping-cough, 49 from diarrhœa, 40 from small-pox, 35 from "fever" (principally enteric), 34 from scarlet fever, and 29 from diphtheria. No death from any of these diseases was recorded last week either in Leicester or in Bolton, whereas they caused the highest death-rates in Manchester, Sunderland, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Huddersfield, Sunderland, and Newcastle-upon-Tyne; from whooping-cough in Sheffield and Bristol; from scarlet fever in Sunderland and Wolverhampton; and from "fever" in Halifax and Norwich. The 29 deaths from diphtheria in the twenty-eight towns included 15 in London, 4 in Cardiff, 3 in Birmingham, and 2 in Portsmouth. Small-pox caused 69 deaths in London and its outer ring of suburban districts, 2 in Sunderland, 1 in Manchester, and 1 in Leeds. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased from 830 to 879 in the previous two weeks, further rose last week to 910; the admissions also rose to 185 last week, from 179 and 141 in the preceding two weeks. The Highgate Small-pox Hospital contained 91 patients on Saturday last, 22 having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 448 and 478 in the previous two weeks, further rose last week to 512, and exceeded the corrected average by 2. The causes of 109, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Sheffield, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 23·3 and 25·0 per 1000 in the preceding two weeks, declined again to 23·4 in the week ending the 11th inst.; this rate was 1·6 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 5·0 and 17·5 in Perth and Aberdeen, to 27·3 in Paisley and 29·0 in Glasgow. The 570 deaths in the eight towns included 24 which were referred to measles, 17 to whooping-cough, 10 to "fever" (typhus, enteric, or simple), 8 to diarrhœa, 6 to scarlet fever, 3 to diphtheria, and not one to small-pox; in all, 68 deaths resulted from these principal zymotic diseases, against 73 and 84 in the preceding two weeks. These 68 deaths were equal to an annual rate of 2·8 per 1000, which was almost identical with the rate (2·9) from the same diseases in the twenty-eight English towns. The 24 cases of measles, of which 22 occurred in Glasgow and 2 in Dundee, showed a further increase of 1 upon the numbers in the previous two weeks. The deaths from whooping-cough, on the other hand, declined to 17, from 35, 32, and 34 in the preceding three weeks; 10 occurred in Glasgow, and 2 each in Dundee, Leith, and Paisley. The 10 deaths referred to "fever" showed an increase upon recent weekly numbers, and included 6 in Glasgow and 2 in Greenock. The 8 deaths attributed to diarrhœa were 12 below the number in the corresponding week of last year. The 6 fatal cases of scarlet fever, of which 4 occurred in Glasgow, showed a decline of 5 from the number in the previous week. It appears that in Scotland chicken-pox is still classed as small-pox; this is contrary to the classification adopted in the English and Irish returns since 1881. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 122 and 130 in the previous two weeks, further rose to 134 last week, and were 22 above the number returned in the corresponding week of last year. The causes of 77, or nearly 14 per cent., of the deaths in these Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 40·4 and 33·6 per 1000 in the preceding two weeks, further declined last week to 32·2. During the thirteen weeks of last quarter the death-rate in the city averaged no less than 34·0 per 1000; whereas in London and in Edinburgh the rate did not exceed 20·8 and 20·0 respectively. The 218 deaths in Dublin last week showed a further decline of 9 from the high numbers in the preceding two weeks, and included 29 which were referred to the principal zymotic diseases, against 32 and 24 in the previous two weeks; 19 resulted from measles, 4 from diarrhœa, 2 from "fever," 2 from diphtheria, 1 from scarlet fever, 1 from whooping-cough, and not one from small-pox. These 29 deaths were equal to an annual rate of 4·3 per 1000, the rates from the same diseases not exceeding 2·7 in London and 0·8 in Edinburgh. The fatal cases of measles in Dublin, which had been 16, 12, and 13 in the preceding three weeks, rose last week to 19, and exceeded the number in any previous week of this year. The deaths referred to "fever," on the other hand, showed a further decline from recent weekly numbers. The 2 deaths from diphtheria were above the weekly average. Nine inquest cases and 5 deaths from violence were registered; the 54 deaths in public institutions were considerably below the average in recent weeks. The deaths both of infants and of elderly persons somewhat exceeded the number in the previous week. The causes of 30, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Dr. Doyle Glanville has gone to the Soudan with the New South Wales Contingent as Staff Surgeon. Dr. Glanville was attached to Colonel Durnford's column, consisting of 2000 men, the whole of whom, including Colonel Durnford and the 1st 24th Regiment, were massacred with the exception of some thirty survivors only. Dr. Glanville escaped, having been ordered to march out the night previously with a party of reconnaissance, and was three miles away from camp when it was attacked. He was then placed on the medical staff of General Wood's column, and served with the flying column, and was present at the battle of Ulundi, when he was mentioned in Sir Evelyn Wood's despatches for distinguished conduct, published in the *London Gazette*, August 21st, 1879. After the battle of

Ulundi the column was disbanded, and Dr. Glanville was then attached to the 1st King's Dragoon Guards, Lord Wolseley's military escort, and proceeded with them through the Transvaal.

War Office.—Army Medical Staff: Surgeon-Major Albert Benjamin Robinson is granted retired pay, with the honorary rank of Brigade Surgeon. Surgeon-Major James Henry Ussher, M.B., has retired on temporary half-pay.

Militia Medical Staff.—Surgeon Thomas Dodson Palmer, 8th Brigade, North Irish Division, Royal Artillery, to be Surgeon-Major.

Admiralty.—The following appointments have been made: Staff Surgeon Alexander Flood, to the *Forward;* Staff Surgeon Stewart F. Hamilton, to the *Dolphin;* Staff Surgeon Charles W. Maynard, to the *Penelope;* Staff Surgeon Michael Fitzgerald, additional, to the *Hibernia;* Staff Surgeon T. D. Gimlette, to the *Euryalus;* Fleet Surgeon Edward Meade, to the *Iron Duke;* Staff Surgeon William F. Spencer, to the *Triumph;* Staff Surgeon Henry J. Madders, to the *Duke of Wellington;* Surgeons Henry F. Kiewiez and C. L. Nolan, to the *Iron Duke;* Surgeon Robert F. Yeo, to Sheerness Dockyard; Surgeon Justin F. Donovan, M.D., to Malta Hospital; and Mr. Samuel Hamill, to be Surgeon and Agent at Burnham, Brancaster, and Thornham.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeons in Her Majesty's Fleet—viz., Richard Dormer White, M.A., M.D.; John Wilson, M.A., M.D.; Henry John Madders, M.D.; Alexander Flood, Michael Fitzgerald, Stewart Frazer Hamilton, and Charles William Magrane.

In accordance with the notice appearing in the *London Gazette* of May 21st, 1884, Surgeon Thomas Desmond Gimlette has been promoted to the rank of Staff Surgeon in Her Majesty's Fleet.

In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon Henry Scanlan has been placed on the retired list of his rank.

Artillery Volunteers.—2nd East Riding of Yorkshire: Acting Surgeon Arthur Henry Robinson, M.D., resigns his appointment.

Rifle Volunteers.—3rd Hampshire: Acting Surgeon Arthur Vernon Ford, from the 4th Volunteer Battalion, the Essex Regiment, to be Acting Surgeon.—2nd Lanarkshire: Lieutenant Robert Thin Craig Robertson, M.B., is appointed Acting Surgeon.

Correspondence.

"Audi alteram partem."

THE MEDICAL BILL AND THE SCOTCH UNIVERSITIES.

To the Editor of The Lancet.

Sir,—I read with some surprise in your leader of April 11th that Sir Wm. Jenner, in his address at the College of Physicians, attributed the withdrawal of the Medical Bill of last year to the "determined opposition of Scotch universities." Now, I yield to no one in my respect for the personal character and high professional attainments of our President, but he has been led into error in this case by an imperfect consideration of the subject, and his position in Trafalgar-square and as an ex-Royal Commissioner does not entitle him to override the facts of the case. I happened to hear every word that was spoken on the three occasions when the Bill was under discussion, and can remember nothing which would imply determined hostility on the part of the Scotch universities, whose adverse influence, if exerted to the full, would no doubt have been disastrous, if not fatal, at any period of legislation. If you will refer to Hansard, you will find that after two full debates on the second reading a further stage was reached on June 30th, when Mr. Mundella moved "that the Speaker do now leave the chair." This was agreed to after some wrangling from quarters not usually favourable to the unobstructed work of the House, and it was further arranged that the Committee should be taken in not less than a week, so that amendments might be put down and duly criticised. Then came the collapse. The action of the House of Lords suddenly paralysed legislation, and Mr. Gladstone announced that he should withdraw all Bills which had not passed through the grand Committees. As the Medical Act Amendment Bill came under this hard-and-fast rule, it had to be ruthlessly flung overboard without reference to popularity, or opposition, or stage of progress, and neither Mr. Mundella nor the House, nor any university or corporation, nor influence, however powerful, could save it from a fate which it shared with many others. The general impression was that if accident had not thus abruptly checked its career, the Bill had a good chance of passing; but the opinion was equally unanimous that Sir Lyon Playfair's amendment would have materially smoothed the way to the ultimate goal of success, and would certainly have saved the licensing bodies from damage, and possibly from ruin. I have always been surprised at the equanimity with which universities and corporations seemed to view their future prospects as affected by the Bill, and by the small amount of alarm which they showed at its destructive tendencies. It is surely utopian to believe that the ordinary rank and file of medical students, whose time and money are not too abundant, will wish to obtain anything beyond the simple right to practise conferred by the Conjoint Board, and the purveyors of fancy qualifications would soon perish from sheer inanition under the provisions of the Bill. Sir Lyon Playfair's amendment would have prevented these risks, and his able advocacy of his views contributes, if that were possible, to increase the estimation in which he is held in the House as an able and eloquent exponent of all that is soundest and best in education and science.

I am, Sir, your obedient servant,

Reform Club, April 14th, 1885. Robert Farquharson.

*** Dr. Farquharson's views are entitled to much respect; but he will not shake the general opinion, as well as Sir William Jenner's, that the Scotch Universities, represented in Sir Lyon Playfair's amendment, really sealed the fate of the Bill which they had previously assented to. The other opposition was unreal and confessedly obstructive; that of Sir Lyon Playfair was subtle, but fundamental and serious. We are sorry that it should have the countenance of Dr. Farquharson, who, as a most worthy alumnus of the University of Edinburgh, should not be so fearful of the interests of his *alma mater.* Does he carry his admiration of Sir Lyon so far as to justify the way in which he misled the House by conjuring up a community with an inadequate supply of medical men, by largely overstating the waste of the profession, which, on the contrary, is overstocked and underpaid?—Ed. L.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS AND THE ASSOCIATION OF MEMBERS.

To the Editor of The Lancet.

Sir,—May we be permitted through the medium of your columns to protest, on behalf of the Association of Members of the College, against the unconstitutional course of action which has been adopted by the Council of the Royal College of Surgeons of England with regard to the new Charter.

In March of last year, at the general meeting of Fellows and Members, a resolution was passed requesting "that no *alteration in the constitution or relations of the College* should be effected without the consent of the Fellows and Members convened to discuss such alteration." This request has recently been repeated at the College by the delegates of the Association of Fellows, but has been ignored by the Council, who have determined to forward without delay to the proper authorities the proposed alterations in the Charter, *on the ground that they were, in part,* submitted to the general meeting in March, 1884. If the proposed form of the new Charter had been acceptable to the profession, the Associations of Fellows and Members would not now be in existence. The Fellows and Members collectively *may* be said to constitute the College, and they are agreed that no Charter should be presented to the Home Secretary without their united approval. It would appear, therefore, that the Council are attempting to legislate in direct opposition to the wishes of their whole constituency.

Furthermore, according to the present Charter no meeting of the Fellows and Members is permitted, unless the Council *approve the object of such meeting*. This monstrous infringement of the liberty of the subject has been embodied in the draft of the new Charter with only a slight alteration in the wording. It seems hardly credible in these days of freedom of the press and liberty of action that a large, intelligent, and educated body of Englishmen should be debarred from holding public meetings for the discussion of questions relating to their government, their dignity, and their interests in a country which has been immortalised by the Poet Laureate as

> "The land where, girt with friends and foes,
> A man may speak the thing he will."

Since the Council of the College have persistently refused to consider the interests of its Members, and have turned a deaf ear to their appeals, the Association of Members have come to the conclusion that the only remedy for the unsatisfactory state of affairs which now exists is for Members of the College to obtain the right of electing their own representatives—either Fellows or Members—to sit upon the Council. In order to effect this reform, they have determined, much as they regret the necessity for such a step, to petition the Home Secretary to refuse to grant any Charter which does not provide for the representation of Members on the Council. A petition has been drawn up, and has already been signed by nearly a thousand Members. The Association of Members have, furthermore, determined to invite all Members of the College to attend the annual general meeting of the Association for the purpose of discussing what further steps must be taken in order to obtain such reforms as are felt by the profession to be most urgently needed in the administrative department of the Royal College of Surgeons. The meeting will be duly advertised in the medical journals, and will be held on May 5th, at 4 P.M., in the Westminster Town Hall.

Trusting to the ready manner in which you have always advocated any measure for promoting the interests of the medical profession, we take the liberty of transmitting to you this protest against what we consider to be a most unconstitutional measure on the part of the College authorities. We beg to subscribe ourselves, Sir, your obedient servants,

WARWICK C. STEELE,
J. NIELD COOK,
W. ASHTON ELLIS,
Hon. Secs. to the Association of Members of the Royal
College of Surgeons.

Western Dispensary, Westminster, April 13th, 1885.

INFECTIVE PHTHISIS.

To the Editor of THE LANCET.

SIR,—With reference to that part of Dr. Weber's Croonian lecture which appeared in your impression of March 14th, which implies that the power of imparting their own properties to outsiders inherent in the infective changes that take place in the lungs of phthisical patients "has been surmised long ago, even before the history of inoculation, which dates back at least as far as 1843," allow me to observe that this "surmise" is entitled to a far higher ancestry or antiquity than is claimed for it here. I published in THE LANCET of Dec. 4th, 1880, a short note of an occurrence in point which I took from a little brochure, entitled "Cardinal Allen's Defence of Sir William Stanley's Surrender of Deventer," Chetham Society's publications, p. 69, and I find from that very accessible compilation, Copland's Dictionary, article "Tubercular Consumption," p. 1125, that "although the occasional transmission of this disease by infection was believed, not only by Galen, but also by ...... several other writers [whose names he gives], yet that 'it' [the question of transmission by infection] still remains in doubt." Whether this doubt will survive the recent discovery of a special bacillus I will not here stop to inquire. What I wish to do is to point to the fact that a belief in the infective character of "pulmonary phthisis"—be the same acute or chronic—has existed from a much earlier date than that given above. Smollett, I think it was, showed that such was the impression, in his day, in Italy and elsewhere in the south of Europe.

"There was," says Ennemoser,[1] "a universally accepted belief in ancient times that living together and breathing upon any person produced bad as well as good effects ...... and pure virgins and young children were supposed able to free persons from diseases by their breath." He quotes the case of David from the Book of Kings, Bacon, Galen, and several others in this direction, and adds that "Rudolph of Hapsburgh is said, ... when very old and decrepit, to have kissed, in the presence of their relatives, the daughters and wives of princely, ducal, and noble personages, and to have derived strength and renovation from their breath. The Emperor Frederick Barbarossa, near the end of his life, was advised by a Jewish physician to have young and healthy boys laid across his stomach instead of using fomentations; and Johannes Damascenus, or Rabbi Moses, relates that for lameness and gout nothing better could be applied than a young girl laid across the affected part."

Discussing this question from this very standpoint in 1666, Gideon Harvey, M.D., whose book, called "Morbus Anglicus, or the Anatomy of Consumption," gave rise to the name "English disease," for this ailment, after observing that "the spring is bad for consumptives," adds (p. 3) that, "considering its malignity and catching nature, it may be enumerated with the worst epidemicks, since, next to the plague, pox, and leprosy, it yields to none in point of contagion, for it is (he says) no rare observation here in England to see a fresh-coloured, lusty young man yoked to a consumptive female, and him soon after attending her to the grave. Moreover, nothing we find (he continues) taints sound lungs sooner than inspiring the breath of putrid, ulcered, or consumptive lungs, many having fallen into consumptions only by smelling the breath or spittle of consumptives; others by drinking after them; and, what is more, by wearing the cloaths of consumptives, though two years after they were left." There was, of course, exaggeration here, but even that tends to show the current of educated thought in his time, and many of his professional contemporaries held similar views.

William Salmon, whose book, entitled "A Complete System of Physick," appeared in 1686, and who was, moreover, a firm believer in the hereditary transmission of this complaint, says in his "Chapter of a Consumption," p. 278, that "contagion may also be referred hither—i.e., as a cause for them who live familiarly with consumptive people; as we have an instance in a woman that was no way predisposed to a consumption, and yet by lying with a consumptive husband she died of one. You may (he continues) find also other instances in Riverius"; and James, whose ponderous "Dictionary" is dedicated to Dr. Mead, does not hesitate to affirm that "if the miasma of this disorder is not sufficient to induce a phthisis, it is nevertheless capable of promoting it, if there is already a disposition to it." He adds that "this doctrine is confirmed to us by some of the most celebrated physicians," and he quotes several of these in point.

I am, Sir, yours obediently,
WM. CURRAN.

Auriol-road, West Kensington, March, 1885.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE LATE SMALL-POX EPIDEMIC IN DURHAM.

DR. BARRON, the medical officer of health for the city of Durham, refers in his report to the late small-pox visitation. A very severe epidemic of small-pox occurred during the past year; about 400 cases came to the knowledge of the sanitary authority, of which 31 proved fatal. Dr. Barron remarks: "So far as I have been able to discover, the majority of those who died from the disease had never been vaccinated, and of the rest none have been vaccinated since infancy." "One result of the epidemic," Dr. Barron says, "has been to show that a large proportion of the community escaped vaccination," which points to a more stringent carrying out of the Vaccination Acts as a necessity in the future. Dr. Barron says that the epidemic, which began early in March, caused little alarm until the end of September, when it began to assume serious proportions. There was no hospital for the isolation of cases. The sanitary authority and the people themselves seemed blind to the impending danger; it was not until the alarming spread of the disease in October began to cause a wide-spread panic that the county magistrates came forward with the offer of the barracks as a temporary hospital, and the good that has resulted from this public-spirited step no one will venture to deny. Dr. Barron, in his valuable and timely report, urges upon the authority to no longer hesitate in providing a permanent hospital for the reception of infectious cases, and he points out that the free gift by the Chapter of Durham of a site whereon to build this hospital lessens the difficulties which formerly stood in the way, and he further points out that it would be a great assistance in the stamping out of infectious diseases if the authority provided themselves with a disinfecting chamber fitted with the necessary apparatus for the disinfection of bedding, clothing, and other articles, and urges also the need of providing a mortuary, which he has frequently recommended to their notice.

[1] The History of Magic, Bohn's Library, vol. I., pp. 117 18.

MIDDLESBROUGH DISTRESS AND THE DEATH-RATE.

At the last meeting of the Middlesbrough Town Council the high death-rate of the borough came under consideration and the medical officer of health, Dr. Malcolmson, said that the death-rate of the town was increased in a marked degree by illness amongst young children, to a great extent having its origin in destitution. He said that in many of the houses there was not a single blanket, and many of the children had not a single article of flannel underclothing, besides being very insufficiently fed. He was asked if he could suggest any remedy, and he at once said that providing each child with a quart of milk daily, some flannel underclothing, and a blanket at night would tend more than anything else he could suggest to a diminution of the death-rate.

MUNIFICENT BEQUEST OF A DURHAM COAL-OWNER.

I have before mentioned the benefactions of Mr. John Eden of Beamish-park, Durham, to the Durham County Hospital Building Fund. This gentleman, who was an extensive owner of coal royalties, and possessed of immense wealth, died on the 4th ult. at his town residence, Winlaton-crescent, London, at the advanced age of ninety-one, and it has transpired that he has left a legacy of £10,000 to the Durham County Hospital.

THE MEASLES EPIDEMIC AT SUNDERLAND.

The medical officer of health for Sunderland, in his fortnightly return of the mortality in the town, states that during the past fortnight there were 193 deaths, or a rate of 40 per 1000 per annum, against 216 deaths in the preceding fortnight. He (Mr. A. E. Harris) further states that during the past two weeks there were 63 deaths from measles and 33 from diseases of the respiratory organs, or a total of 96.

ALNWICK INFIRMARY.

The many friends of Dr. Brown, late house-surgeon of the Alnwick Infirmary, left in the north will be happy to know that he has obtained the appointment of surgeon to the Red Cross, or National Aid Society for the Sick and Wounded in War. Dr. Brown is already on his way to Cairo, to enter on his duties; and it is certain that he will be accompanied in his mission and work with the best wishes of all who had the pleasure of his acquaintance.

Newcastle-on-Tyne, April 14th.

EDINBURGH.

(*From our own Correspondent.*)

A NEW LABORATORY.

AT a recent meeting of the Royal College of Physicians it was decided to establish a laboratory for experimental work in connexion with the College Library and Hall in Queen-street. The plan that is to be carried out will certainly place great facilities for original work at the disposal of the Fellows. The laboratory is to be fitted with all modern improvements in the way of scientific apparatus and the usual requisites, and the services of a skilled assistant are to be constantly at the disposal of any intending workers. This arrangement will afford, even to those engaged in busy practice, the opportunity of working up cases of special interest, for a few hours' notice to the assistant will suffice to place every requisite in readiness for their use; and the sacrifice of time usually necessary for the arrangement of minor details will thus be entirely obviated. The project is an admirable one, and will doubtless be carried out in a manner not unworthy of a body which maintains one of the largest and best appointed medical libraries in the world; and it can apply the large fund at its disposal to no more beneficial and praiseworthy purposes than these.

ERECTION OF A BOARD SCHOOL AND PUBLIC BATHS.

One of the oldest and most sacred objects of medical interest in Edinburgh has suddenly and silently vanished. The old infirmary of Monro Primus and of Provost Drummond, which till within the last few weeks has stood empty and forlorn, though very picturesque, has succumbed to the reforming efforts of an energetic Town Council and is making way for a large Board-school and handsome public baths. The latter especially have long been a great desideratum in Edinburgh, and the proposed structure will do much towards satisfying the requirements of the city in this respect. Commodious swimming and plunge baths are to be provided, and two extensive public laundries are to be attached to the premises; these will be a great boon to the crowded population of the district in which the building is to be constructed. Although one is bound to rejoice in the material advantages which the alterations will effect, one can but feel a pang at parting with the quaint old building where the fame of Edinburgh as a medical school was made, and where the vivid recollections of so many find a centre. Nor is it only to old students of the Edinburgh school that this building has a special interest: an even wider circle think with a touched interest of the scene where the saddest and most thrilling part of "Rab's" career was enacted. It is fortunate that in this case the hand of change brings with it little of a real desecration.

WORK AT THE MEDICO-CHIRURGICAL SOCIETY.

At the meeting of the Medico-Chirurgical Society held on April 1st several cases of considerable interest were exhibited. Mr. Joseph Bell showed a patient from whom he had removed the whole of the os calcis and a portion of the astragalus subperiosteally, the insertion of the tendo Achillis being preserved. The whole of the removed bone has been replaced by osseous growth from the periosteum, and a useful foot with normal movement at the ankle has been the result. Mr. A. G. Miller exhibited a patient suffering from ununited fracture of the scapula. The case was one of a severe railway injury, and there were complications in the shape of a dislocation of the shoulder joint and fractures in other parts of the body. The fracture of the scapula was recognised at the time of the accident, but the patient absolutely refused to submit to any retentive treatment. The symptoms which are present furnish some points of great interest in regard to a differential diagnosis. In one position of the parts the fracture closely simulates subcoracoid dislocation; there is flattening of the shoulder, and a slight forward bulging is seen immediately below the coracoid process. The distortion can, however, be completely removed by drawing the elbow upwards, and during this movement the tip of the coracoid process itself is felt to glide in an upward and inward direction. Whether the limb be in the distorted or in the natural position, the patient can perform all normal movements at the shoulder-joint. The movement of the coracoid process shows that it is involved in the fracture, and the diagnosis arrived at is that of a fracture of the surgical neck of the scapula, with stretching of the coraco-clavicular ligaments; the line of the fissure running through the supra-scapular notch and separating the coracoid process along with the glenoid cavity, as was described by Sir Astley Cooper. Mr. Joseph Bell showed a number of gall-stones removed by operation from an ulcerated gall-bladder, which communicated by a sinus with the external abdominal wall. Dr. Littlejohn, the president of the Society, exhibited a preparation of the air passages from a case of carbonic oxide poisoning, which illustrated the great congestion of the mucous surfaces present in that condition. Dr. R. Milne Murray then read his paper on the "Cessation of Respiration under Chloroform and its Restoration by a New Method." The paper was based on some important observations that he has made recently upon the administration of chloroform to rabbits. By means of an ingenious contrivance, Dr. Murray was able to regulate exactly the strength of the chloroform vapour which the animals inhaled. The effects on the respiration were recorded by a new method, in which a manometric recorder, indicating equal increments of pressure by equally increased excursions of the recording style, was substituted for the ordinary tambour recorder, which, after a certain degree of pressure is arrived at, fails in that respect. The readings from the recording apparatus were neatly mounted for exhibition, and by passing them round amongst the members present many of the most important parts of the paper obtained remarkably clear illustration and confirmation. One point of great practical importance indicated by these graphic methods was that in deep narcosis the respiratory heavings of the thoracic walls may go on to all appearance perfectly, and yet absolutely no vapour enter or leave the chest. Dr. Murray considers this condition to be one of respiratory incoördination, the motor coördinating centre being affected, resulting in a "respiratory stammer," in which, although the thoracic walls rise, there is no depression of the diaphragm, but a contraction of the abdominal muscles, which nullifies the effect of thoracic expansion. As a result of his experience in cases of suspended respiration from the use of chloroform, Dr. Murray strongly insists on the importance of withdrawing the chloroform vapour from the lungs before commencing to introduce pure air. He advocates the introduction of a tracheal catheter in the human subject in such cases, and the removal by suction of as much of the vapour as possible before inducing artificial inspiration by the ordinary means. In rabbits he found that where this method was adopted resuscitation could be achieved even after a prolonged suspension of respiration, whereas were the ordinary means adopted, a successful issue was rarely attained.

IRELAND.

(*From our own Correspondent.*)

VISIT OF THE PRINCE OF WALES.

THE honorary degree of Doctor of Laws of the Royal University of Ireland was conferred on His Royal Highness last week; and on the same occasion the Princess of Wales received the honorary degree of Doctor of Music. At the University of Dublin an illuminated address was presented by the Senate of the University, and, at the request of His Royal Highness, the provost granted the undergraduates a term. Of the numerous addresses presented, I shall merely llude to those from the Royal College of Surgeons, the College of Physicians, and the Academy of Medicine. The address from the College of Surgeons alluded to the foundation of that institution by Royal Charter granted by George III., and stated that the College, unswerving in loyalty, uninfluenced by political or sectarian feeling, had never relaxed its efforts efficiently to discharge the trust confided to it by improving the profession, and thus promoting the welfare of the nation at large, and particularly by providing a sufficient number of properly educated surgeons, as well for the public in general as for the army and navy. The College of Physicians in their address referred to the satisfaction the visit of the Royal Family had produced, and alluded to the favour the Prince had always extended to their profession, as shown by the interest he had displayed in its efforts for the advancement of medical science and the preservation and improvement of the health of the nation.

HONOURS FOR THE MEDICAL PROFESSION.

It has been suggested that during the visit of the Prince of Wales to Ireland an opportunity will arise for the recognition of the long-deferred claims of the medical and surgical members of the profession in Dublin to the bestowal of honours by the Crown. Since the days of Sir Philip Crampton and Sir Dominic Corrigan, no surgeon or physician in this country has received a share of the numerous baronetcies bestowed by the Government; and this neglect has been a grave source of regret, as appearing to mark their inferiority as regards their English and Scotch brethren. It would be invidious for me to mention names, but there are several, both medical and surgical, who are eminently qualified for the honour in question.

RICHMOND DISTRICT LUNATIC ASYLUM, DUBLIN.

In the report of this asylum for the past year, Dr. Lalor, the resident physician, states that he has been enabled lately to carry out a useful measure in the separation of the epileptic from the general insane, and the grouping of a comparatively small class, consisting of them and the very aged and infirm, in a building to themselves, with access to the recreation rooms. Although the arrangement has only been a short time in operation, the beneficial results of the change have been acknowledged. The total cases under treatment during 1884 were 1519, the daily average being 1068; and it is interesting to note as an indication of the method of treatment that the daily average of patients employed in one way or another was 860.

RETIREMENT OF DR. BRODIE, LOCAL GOVERNMENT BOARD INSPECTOR.

At a meeting of the Poor-law medical officers of the Cork district, held on the 4th inst. at the Royal Cork Institution, Dr. Wycherly, J.P., High Sheriff, in the chair, the following resolution, proposed by Dr. O'Callaghan and seconded by Dr. Golding, was adopted:—"That the Poor-law medical officers of the Cork district cannot permit Dr. Brodie to sever his connexion with them without testifying in a proper manner their appreciation of his character as an inspector; that the necessary steps be taken to present Dr. Brodie with an address and testimonial on his retirement; and that Dr. Donovan be requested to act as secretary, and Dr. O'Connor, jun., as treasurer." Several who were unable to be present at this meeting have expressed their intention to co-operate in the movement.

ALEXANDER MEMORIAL PRIZE.

The triennial prize, founded in memory of the late Dr. Alexander, Director-General of the Army Medical Department, consists of a gold medal value £10, with £50 in money, and is open to competition by officers of the Army Medical Staff. This year it was gained by Surgeon John Martin, who is now in Egypt, for his essay on "Antiseptic Surgery, and its Application in Military Hospitals and in the Field." It is very creditable to Surgeon Martin, who is a native of Cork and received his professional education at the Queen's College, that this is the second occasion upon which he has obtained this distinction, the subject of his former essay having been "On the Influence of Drinking-water in causing Enteric Fever and Cholera."

Dublin, April 14th.

PARIS.

(*From our Paris Correspondent.*)

DEATH OF A LADY DOCTOR.

THE death of Mrs. Emilie Bovell-Sturge, Doctor of Medicine of the Faculty of Paris, and Officier d'Académie, occurred at Nice on the 2nd inst. Mrs. Bovell-Sturge began to study medicine at Edinburgh in 1871, but finding the way to successful study barred there, she went to Paris in 1873, where she took her degree in 1877. The subject of her thesis was "Les Phénomènes congestives consecutives aux Attaques de l'Epilepsie et de l'Hystéro-Epilepsie," for which she was highly complimented. After having obtained the Doctorate of Paris, she went to London to commence practice, and there married Dr. Allen Sturge. Soon after this she was appointed physician to the new Hospital for Women in the Marylebone-road, which post she held till she was compelled to leave London on account of her health, in October, 1881, when she was accompanied by her husband to Nice, where they both settled in practice. She has read papers at the Congrès d'Hygiène at Paris in 1878, on the Improved Industrial Dwellings in London; at that of the Hague last year on the method employed in England for dealing with the question of Pauper Children; and before the Société Médicale de Nice on "Some Points in the Pathology of Fibroid Phthisis." Mrs. Bovell-Sturge very modestly limited the sphere of her work to the diseases of women and children, without disconnecting herself from questions of general professional interest.

THE FRENCH SURGICAL CONGRESS.

The first Congrès Français de Chirurgie, which took place at Paris from the 6th to the 12th inst., was presided over by Professor Trélat. Before entering into the technical objects of the meeting, a discussion took place as to whether other cities than Paris could not be selected in rotation for the seat of the meeting. It was decided that Paris should be the constant *locale* of future congresses. Another question arose as to the period of the annual meeting, as that at which it has just taken place has for many reasons been found to be particularly inconvenient. It has therefore been decided that it should be held in the second fortnight of October of each year. M. Trélat then addressed in neat terms a welcome to the foreign visitors, and passed in review the various discoveries which have actually renovated surgery, and given it an impetus which has been taken advantage of for the last twenty years. In doing this he recalled the discoveries of anæsthesia and of antisepsis, with which he connected the honoured names of Pasteur, Lister, and Alphonse Guérin. He showed that, thanks to these conquests, the limits of surgery have been considerably extended, and that the rightful claim of surgery to be an art based on science has been fairly established. He then inquired as to whether in this renovation and rapid extension, in which nations and individuals have made such gigantic strides, French surgery has in any way lost the high reputation it has hitherto held among other nations. The answer of course would be in the negative. In looking over the subjects that were discussed at the Congress, I cannot say that there has been anything particularly new or important brought forward.

THE INTERNATIONAL CONGRESS OF HYDROLOGY AND CLIMATOLOGY.

To your note in The Lancet of last week on the International Congress of Hydrology and Climatology, which is to be held at Biarritz in October, 1886, I may add that for the sum of 12 francs anyone may become a member. Application should be accompanied by a post-office order for the above sum, which will entitle each member to—(1) the documents relative to the different sections of the Congress, to the subjects that will be brought before it, and to a detailed plan of the excursions; (2) a card giving members the right to travel by rail to Biarritz at a reduced fare of 50 per cent.; (3) a memorandum giving a detailed account of the price of lodgings, &c. The Committee of Organisation particularly requests that those desirous of becoming members should make known their intention as soon as possible. Further information may be obtained from Dr. Durand-Fardel of Paris, or from Dr. Garrigou of Toulouse.

Paris, April 14th.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Acts Amendment Bill.

Owing to the absence of the Lord Chancellor from the House of Lords this week, in consequence of the decease of the Countess of Selborne, the second reading of the Lunacy Acts Amendment Bill has been postponed until Tuesday next.

On Monday, the Burgh Police and Health (Scotland) Bill was read a second time.

Over-pressure in Elementary Schools.

In the House of Commons on the 13th inst., Mr. Talbot moved an address to the Crown praying that a larger proportion of the grant now given to public Elementary Schools should be allotted in the form of a fixed payment on average attendance. By this distribution of the grant he contended that over-pressure in elementary schools would be prevented. Mr. R. Paget seconded the motion, which was strongly opposed by Sir L. Playfair, who asserted that its effect would be to increase the remuneration of bad schools and to decrease the payments for good schools. After some remarks from Lord G. Hamilton, Mr. Forster, and Mr. J. A. Campbell, Mr. Mundella maintained that to secure good teaching there must be some testing of results, and this could only be done by individual examination. There was no new departure in the Code, and no Code had ever been so threshed out as this. It had received universal assent, and, whatever its defects, more thorough work was being done and better grants were being earned under it than under any previous code. In like manner, he contended payment by results had secured good teaching without interfering with freedom of action on the part of teachers and managers. He dwelt upon the large and increasing sums annually spent on education, and contended that State aid must be administered under State control. As to over-pressure the weight of evidence was, he stated, all the other way. On a division the motion was negatived by 117 to 53.

The Contagious Diseases Acts.

On the 14th inst., in reply to Mr. Bulwer, who asked the Secretary for War whether it was a fact that the number of soldiers serving at home admitted to hospital for venereal disease had during the past year largely increased and was still increasing, and whether he had any objection to lay upon the table of the House a return similar in form and detail to, and in continuation of, that presented to the House on the 3rd of March, 1884, showing the number of soldiers admitted to hospital for venereal disease since the end of the year 1883, Sir A. Hayter stated that there has been an increase of admissions to hospital for the cause referred to in the districts formerly protected from 110 per 1000 in 1883 to 135 per 1000 in 1884. The return in continuation of that presented in 1884 would be given if moved for.—Mr. Cavendish-Bentinck asked whether in the return about to be laid upon the table the War Office will distinguish between the various forms of venereal disease, so as to show the proportions in which the soldiers have been affected during the past year, and on this point Sir A. Hayter promised to make inquiry.

Medical Officer of Health for Cheltenham.

On Thursday, Mr. J. Campbell having asked the Secretary of the Local Government Board if he could state the result of his inquiries into the circumstances of the recent appointment of a medical officer of health by the Town Council of Cheltenham, Mr. G. W. E. Russell said he had obtained further particulars as to the appointment of Mr. Roch. It was true that when he was appointed he had a surgical qualification only. The regulations of the Board require that unless they dispense with the requirement, a medical officer of health shall possess both a medical and surgical qualification, and in the case of a borough such as Cheltenham they would not have consented to the office being held by a medical man with one qualification only; but Mr. Roch, about three weeks before the date when he was to enter upon his duties, obtained the requisite medical qualification. The Town Council, when this further qualification had been obtained, ratified the election by formally applying to the Board to dispense with the requirement referred to, so far as was necessary, in consequence of Mr. Roch not actually possessing at the time of the election the double qualification. The Board had complied with their request, and have sanctioned the appointment.

Obituary.

EDWARD WELLS, M.D. Oxon.

We *regret to have to record the death of Dr.* Wells of Reading, senior physician to the Royal Berkshire Hospital. Till three weeks ago Dr. Wells was fully engaged in the active duties of his profession, and it was hoped that a change to the Isle of Wight and rest from arduous duties would restore his broken health. He graduated at Oxford in 1840, and was Radcliffe travelling fellow of the University. After three years' professional study on the Continent he settled at Reading, in succession to the late Dr. Smith, father of the well-known Goldwin Smith. As physician to the Reading Hospital and Dispensary he was much beloved by the poor. Among his professional brethren he was highly esteemed, not in the town only but throughout Berkshire, and had accorded to him very rightly the honourable position of the principal consulting physician in the county. His education at Winchester and Oxford gave him many friends of position, but it was chiefly his gentle and pious nature which endeared him so much to his professional brethren and all who had the advantage of his acquaintance.

EDWARD DAVY, M.R.C.S.

On January 26th, the death occurred at Malmesbury, Australia, of Mr. Edward Davy, whose name has been recently before the public as the discoverer of the "relay" system, which had an important influence in the development of the electric telegraph. Born at Ottery St. Mary, Devon, in 1806, he studied at St. Bartholomew's Hospital, obtained the licence of the Society of Apothecaries in 1823, and became a Member of the Royal College of Surgeons in 1829. He then commenced the practice of his profession; and it was not until 1836 that he first experimented in electric telegraphy. Mr. Fahie's articles in the *Electrician* in July and August, 1883, and his "History of Electric Telegraphy," published by Spon (London) last year, do ample justice to Mr. Davy's early inventions and their importance in developing the practical use of electric telegraphy. In 1839 Mr. Davy emigrated to South Australia, going out in medical charge of an emigrant vessel. He contemplated pastoral pursuits, but soon abandoned the idea, and in 1843-45 was engaged as editor of the *Adelaide Examiner*. In 1848 he undertook the management of the Yatala smelting works. In 1852 he took charge of the Government Assay Office in Adelaide, and in 1853 he organised and took the management of a similar establishment in Melbourne. The Assay Department was at the end of the following year abolished, and Mr. Davy removed to Malmesbury, where the remainder of his life was spent. He took an active part in local affairs, was for many years a member of the borough council, was several times mayor, and was for more than twenty years an active justice of the peace.

GEORGE SANKEY, M.R.C.S., L.S.A.

We regret to record the death of Mr. George Sankey, one of the most honoured and respected members of the profession in Maidstone. Mr. Sankey had been in failing health for some months, and was advised to take a voyage to Australia to recruit his strength. He started from Gravesend in the *Chimborazo* on January 8th, and experienced very rough and cold weather, owing to which an attack of pneumonia demonstrated itself, and death resulted during the passage of the ship through the Red Sea.

Mr. Sankey received his medical education at St. Thomas's Hospital. He became a member of the Royal College of Surgeons and licentiate of the Apothecaries' Society in 1854. He was appointed senior surgeon of the Army Works Corps in the Crimea, and on his return to England settled in Maidstone, where he rapidly acquired a large practice. In 1870 he was appointed surgeon to the West Kent General Hospital, and after holding this important office for twelve years became consulting surgeon, which post he held till his death. His sterling integrity won for him a large circle of friends amongst his professional brethren and the general public.

Medical News.

Princess Christian, of Schleswig-Holstein, paid a visit on the 15th inst. to the London Hospital.

The fund raised up to the present time for the erection of a hospital at Port Said, as a national memorial to General Gordon, amounts to between £14,000 and £15,000.

North-Eastern Hospital for Children.—The Princess of Wales will open a bazaar on behalf of the funds of this hospital on June 24th next, at the Cannon-street Hotel.

Vaccination Grants.—Dr. Newham, of Winslow, (ninth time), and Dr. P. L. Benson, of the Buckingham Union, have received the Government grants for successful vaccination.

Mr. Francis Wicksteed, M.R.C.S., L.S.A., Consulting Surgeon to the Weston-super-Mare Hospital, has been elected by the ratepayers a Member of the Weston Local Board of Health.

Royal College of Surgeons.—The Library of this institution will be closed on Tuesday next, the 21st inst., owing to the large number of candidates who have entered their names for examination for the diploma of Membership of the College, amounting, we are informed, to 270.

The Water-supply of Lincoln.—An exhaustive report in reference to the water-supply of Lincoln has been presented to the corporation of the city by Dr. Harrison, the medical officer of health. The conclusions at which he arrives are:—(1) That the water, after filtration, as supplied, contains an excess of organic matter, making it only a second-class water. (2) That the sources of the water are polluted by drainage from land highly cultivated and occasionally manured with nightsoil; water from such a source is dangerous. (3) That the quantity available is not sufficient for the wants of the city. (4) That the filter-beds are capable of filtering more than a million gallons daily. (5) That it is not advisable to take the water from the River Witham for the supply of the city.

Large Bequests to Hospitals.—A bequest of £10,000 has been made to the Durham Infirmary by the late Mr. J. Eden, of Beamish-park, near Durham.—The late Captain Perry, of the Wergs Hall, has left £5000 to the Wolverhampton and Staffordshire General Hospital, and £250 to the Wolverhampton Eye Infirmary.

National Hospital for the Paralysed and Epileptic.—The Prince of Wales has consented to open the new building attached to this hospital during the month of June next. The new hospital, of which the west block forms a memorial to the late Duke of Albany, has been erected at a cost of nearly £80,000, of which all but a balance of £6500 is provided.

Sewage Works at Buxton.—On the 9th inst., the new sewage works, which have been recently erected at Buxton at a cost of about £4000, were formally opened. The works have been constructed for the purpose of treating the town sewage by precipitation with iron-water and lime, the iron-water being conveyed from a disused colliery at the foot of the Axe Edge hills.

Glasgow University Medico-Chirurgical Society.—At the annual business meeting of this Society, the following were elected office-bearers for next session:—Honorary President: Professor Leishman, M.D. President: John Macphail. Vice-Presidents: Senior, John H. Carslan, M.A.; Junior, Basil J. Adam. Secretaries: Corresponding, William H. Fergus; Minute, Henry J. Younger, M.A. Treasurer: Arthur D. Hughes. Librarian: William B. Leishman.

Seamen's Hospital Society.—At a recent quarterly court of the governors of this Society, the Committee reported that the drainage works, now being carried out for the purpose of placing the building in a sanitary condition, are progressing favourably, while the chapel is completed externally. To meet this expenditure the committee have been obliged to sell a further £2000 worth of stock, and contributions in aid of the special fund for drainage improvements and the chapel are urgently needed.

New Workhouse for the Holborn Union.—On the 14th inst., the foundation-stone of a new workhouse for the Holborn Union was laid by Mr. Garrod, chairman of the Board of Guardians. The building will accommodate 1000 able-bodied poor, and is to take the place of the recently demolished workhouse in the Farringdon-road, and the institution in Gray's-inn-road, which it is expected will in a short time be condemned. The new erection is situated near Tooting, and is estimated to cost £65,000, which will include the furnishing.

In Memoriam: Samuel Rabbeth.—A handsome brass tablet to the memory of the late Samuel Rabbeth, M.B., was on Saturday last placed by the Committee of Management in the inquest-room of the Royal Free Hospital. The tablet bears the following inscription:—"This tablet has been erected by the authorities of the Royal Free Hospital (Gray's-inn-road) and the medical staff to the memory of Samuel Rabbeth, M.B., M.R.C.S., senior resident medical officer of this hospital, who sacrificed his own life in the endeavour to save that of a little child, a patient under his care. Died October 20th, 1884; aged twenty-six years."

University of Oxford.—The Regius Professor of Medicine has given notice that Examinations for the degree of Bachelor of Medicine will commence in the Medical Department of the Museum as follows:—The second (or final) examination, Monday, June 8th, at 10 A.M.; the first (or scientific) examination, Friday, June 19th, at 10 A.M. Candidates for either of these examinations are requested to send in their names on or before May 23rd, to "the Regius Professor of Medicine, Medical Department, Museum, Oxford." Candidates for the Scientific Examination are to state whether they have passed the Preliminary Honour Examination in the School of Natural Science; and, if not, whether they desire to present themselves for Physics and Chemistry only at this examination, or for all the subjects thereof.

Devonshire Hospital and Buxton Bath Charity. At a meeting of the Committee of Management of this institution held on the 4th inst., it was stated that during the three months ending the 31st ult., 336 in-patients were admitted, or within two of the number admitted during the corresponding quarter of the previous year. The number of out-patients treated was twenty-two. The receipts were larger than in the corresponding quarter of last year, but it was found necessary to draw £500 from the reserve fund to defray the cost of the reconstruction and repairs of the inadequately completed works of the hospital extension.

Shocking Occurrence in a French Hospital.—On the 7th inst., one of the fever patients at the Tenon Hospital was suddenly seized with a fit of raving madness, and escaped on to the roof of the building, whence an attendant who had followed him endeavoured to compel him to return. A desperate struggle ensued, but the patient broke away and jumped to the ground, where he was afterwards found frightfully mutilated and inanimate. The attendant only saved himself from the same terrible fate by clinging with one hand to the stack-pipe until he was rescued by his companions.

Lunacy in Lancashire.—From a return just issued by the clerk to the Rainhill Asylum, it appears that there were on January 1st last 8178 pauper lunatics, idiots, and persons of unsound mind in Lancashire. Four classes of persons furnish very nearly one-fifth of the whole number of asylum inmates—viz., factory operatives 268, labourers 243, domestic servants 184, and housekeepers 456, making a total of 1151. The highest percentage of lunacy occurs in the Manchester Union, being 4·025 per 1000 of the population on the census of 1881; and the lowest occurs in Barrow, where it is ·740.

Infirmary Nurses and Medical Teaching.—A few months back, at the request of Dr. Neale, the Board of Guardians for the Wandsworth and Clapham Union voted a sum of money for the purchase of a skeleton and physiological diagrams, in order that the nurses of the infirmary might receive physiological instruction. On the 9th inst., at the close of the ordinary business of the board, Dr. Neale stated that he had given some twenty demonstrations to the nurses, who had attended well and taken an intelligent interest in the lessons. He had held a written examination, and both himself and Dr. Wilson were surprised at the proficiency shown by the pupils. The examination was a severe one, and both in that and practical work, such as bandaging &c., the nurses had made remarkable progress. Prizes were then presented to the four candidates who were most successful in the examination.

North-Western Association of Medical Officers of Health.—At the monthly meeting of the members of this Association, held on the 9th inst., a resolution was proposed by Dr. Vacher (hon. sec.), seconded by Dr. Kenyon (Chester), and carried, expressing regret that the medical officer of health of St. Pancras (Mr. Murphy) had felt himself compelled to resign his post "in consequence of the hostility of certain members of his vestry rendering it impossible for him to carry out his duties conscientiously and impartially," and asking for the intervention of the Local Government Board, to prevent the loss of this gentleman's services.—Dr. Hime then delivered his inaugural address, which was mainly devoted to the subject of cholera bacillus. He illustrated his remarks by mounted specimens of the bacillus placed under the microscope, and a short discussion followed.—A paper on "The Tenure of Office by Medical Officers of Health" was afterwards read by Mr. J. E. Phythian.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

Abbott, C. E., M.R.C.S.E., L.K.Q.C.P.I., has been reappointed Medical Officer of Health for the Braintree Rural Sanitary District.

Allott, James H. L., M.B., C.M.Ed., has been appointed House-Surgeon to the Dewsbury and District General Infirmary, Dewsbury.

Ashe, Wm. Conyngham, L.R.C.S.I., has been appointed Medical Officer to the Newcastle Hospital, New South Wales.

Battin, John, L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Church Eaton District of the Cannock Union, vice Baddeley, resigned.

Brown, Jas. Wm. H., L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the West District of the Holbeck Union, vice Dobson, deceased.

Clifford, William, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Adare Dispensary, vice Shanahan, resigned.

Cooper, Arthur, M.R.C.S., has been appointed Surgeon to the Westminster General Dispensary, vice Barron, resigned.

Forbes, Armitage, L.R.C.P.Ed., L.R.C.S.I., has been appointed Government Medical Officer and Public Vaccinator for the Tweed River District, New South Wales.

Hawkins, Francis Henry, M.B.Ed., &c., has been appointed Assistant Physician and Registrar to the Hospital for Epilepsy and Paralysis, Portland-terrace, Regent's-park.

Heath, James, M.B.Ed., has been appointed Senior House-Surgeon to the Torquay Hospital, Torquay, vice Thistle, resigned.

Murray, Chas. Stormont, F.R.C.S.I., L.S.A.Lond., has been appointed Administrator of Anæsthetics, Samaritan Free Hospital.

O'Reilly, Walter W. Joseph, M.D., M.Ch.Dub., M.R.C.S., has been appointed Honorary Physician to the Sydney Hospital.

Wardle, Mark Anthony, L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer for the Bishop Auckland District and Workhouse, Auckland Union, vice Hutchinson, deceased.

Whitton, Thos. Bain, M.D., L.R.C.S.Ed., has been appointed Surgeon to the Reefton Hospital, New Zealand.

Yarrow, Geo. Eugene, M.D.Heid., M.R.C.P.L., M.R.C.S., has been appointed Medical Officer for St. Luke's Parish, Holborn Union.

Births, Marriages, and Deaths.

BIRTHS.

Brewer.—On the 11th inst., at "Cairn," Richmond-road, E., the wife of A. H. Brewer, L.R.C.P.L., &c., of a daughter.

Duke.—On the 10th inst., at Locksley, Freshwater, Isle of Wight, the wife of Edgar Duke, M.R.C.S.Eng., L.S.A.Lond., of a daughter.

Duncan.—On the 11th inst., at 6, Harley-street, Cavendish-square, W., the wife of William A. Duncan, M.D., F.R.C.S.Eng., of a daughter.

Finlay.—On the 1st inst., at Montagu-street, Portman-square, W., the wife of David W. Finlay, M.D., M.R.C.P., of a daughter.

Pearce.—On the 8th inst., at The Manor House, Brixton-rise, S.W., the wife of Chaning Pearce, M.D., of a son.

Powell.—On the 10th inst., the wife of R. Douglas Powell, M.D., F.R.C.P., of a son.

Uhthoff.—On the 7th inst., at Western-road, Hove, Brighton, the wife of John Caldwell Uhthoff, M.D., of a daughter.

MARRIAGES.

Bruce—Collingridge.—On the 8th inst., at St. Mary's, Hornsey, by the Rev. F. H. Dalby, M.A., brother-in-law of the bridegroom, assisted by the Rev. J. Jeakes, M.A., Rector of the Parish, Robert Bruce, M.R.C.S., of the City-road, E.C., to Emma, the second daughter of William Hill Collingridge, of Hornsey, N.

Deane—Planck.—On the 2nd ult., at Holy Trinity Church, Allahabad, India, by the Rev. A. O. Hardy, M.A., Andrew Deane, M.D., F.R.C.S.I., Surgeon-Major Bengal Medical Service, Civil Surgeon, Cawnpore, N.W.P., to Lilian Annie, only daughter of Chas. Planck, F.R.C.S.E., Deputy Surgeon-General Bengal Medical Service, Sanitary Commissioner and Inspector-General of Vaccination, North-west Provinces and Oudh.

Humphreys—Spottiswoode.—On the 8th inst., at St. Mary's, Oatlands, Francis Rowland Humphreys, L.R.C.P., &c., of Queen's-crescent, Haverstock-hill, to Cecilia Mainie Spottiswoode, youngest daughter of the late Major-General Spottiswoode, 37th B.N.I.

Penny — Tait. — On the 7th inst., at St. Mark's, Tollington-park, Dr. Charles Hall Penny, of Enfield, to Emily Mary, daughter of the late Greville Ewing Tait, M.R.C.S., and granddaughter of the late Rev. A. S. Acheson, Rector of Teigh, Oakham.

Plucker — Kirkpatrick. — On the 7th inst., at the Church of the Resurrection, Brussels, Theodore Plucker, M.D., Professor of the University of Liège, to Mary Eliza Caroline, eldest daughter of W. H. Kirkpatrick.

Storry—Scott.—On the 8th inst., at St. Thomas's, Haverfordwest, by the Rev. G. C. Hilbers, assisted by the Rev. J. Popkin Morgan, cousin of the bride, Frederick William Storry, M.R.C.S., of Stroud, Gloucestershire, eldest son of Edwin Storry, of Howden, Yorkshire, to Beatrice Eliza, second daughter of the Rev. William Scott, Vicar of Slebech and Minwere, and late Head Master of Haverfordwest Grammar School.

Tirard—Beloe.—On the 8th inst., at Holton St. Peter, by the Rev. Henry Ryder Ware, uncle of the bride, Nestor Isidore Charles Tirard, M.D.Lond., Professor of Materia Medica, King's Coll., Lond., to Helen Mary, second daughter of the Rev. Robert Seppings Beloe, Rector of Holton St. Peter, Suffolk.

DEATHS.

Smith.—On the 12th inst., at Greenhill, Weymouth, William Johnson Smith, M.D., aged 72.

Tibbits.—On the 14th inst., at Bradford, Yorkshire, E. T. Tibbits, M.D., London, fourth son of Thomas Tibbits, 29, Burlington-road, Clifton, aged 45.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 20.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10.30 A.M., and each day at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 P.M., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 P.M., and on Tuesdays at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

Medical Society of London.—8.30 P.M. Mr. Mitchell Banks: On the Treatment of Gangrenous Intestine in Strangulated Hernia, with a successful case of Resection of the Small Bowel.—Dr. Herbert Snow: On the Free Use of Caustic Potash in the Treatment of Cancer of the Cervix Uteri.

Tuesday, April 21.

Guy's Hospital.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

Cancer Hospital, Brompton.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 2.30 P.M.

Central London Ophthalmic Hospital.—Operations, 2 P.M., and on Friday at the same hour.

Royal Institution.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

Pathological Society of London.—8.30 P.M. Mr. Lane: Three cases of Displacement of the Lumbar Vertebræ.—Dr. Turner: (1) Tumours in Adrenals (card); (2) Suppuration of Simple Fracture of the Hyoid Bone (card).—Dr. Goodhart, for Dr. Handfield Jones: The Cerebral Arteries in states of Congestion.—Dr. Willcocks: A case of Hypospadias.—Dr. Percy Kidd: Destructive Disease of the Lung.—Dr. Allchin: Acute Ulceration of the Colon.—Dr. Silcock: Entero-colitis (card).—Dr. Goodhart: Specimens of Enteritis and Colitis (card).—Mr. Battle: Cyst growing from the Wall of the Intestine.—Mr. J. Hutchinson, jun.: Hydrocele of the Cord.—Mr. Bruce Clarke: Two cases of Gastrostomy.—Dr. Hebb: Aortic Valvulitis, with Embolism of a Coronary Artery and Middle Cerebral (card).—Mr. Shattock: Fracture of the Superior Cornua of the Thyroid Cartilage (card).—Dr. Chaffey: Solitary Kidney (congenital) (card).—Dr. Hale White: (1) Enormous Hypertrophy of the Heart (card); (2) Large Triple Phosphate Renal Calculus (card).—Dr. Pitt: (1) Sarcoma of Petrous Bone, Cerebellum, and Naso-pharynx (card); (2) Syphilitic Ulceration of Larynx and Trachea (card).—Dr. Hadden: (1) Broad Ligament Cyst containing Coagulated Albumen (card); (2) Ulceration of Intestine originating in Hæmorrhage (card).

Wednesday, April 22.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

St. Mary's Hospital.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

St. Thomas's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Central Hospital.—Operations, 2 P.M.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 P.M.

University College Hospital.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

Royal Free Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 3 to 4 P.M.

Royal Microscopical Society.—8 P.M. Conversazione.

British Gynæcological Society.—8.30 P.M. Specimens will be shown by Dr. More Madden (Dublin), Mr. Reeves, and Dr. Fancourt Barnes.—Dr. More Madden: On some Points in the Treatment of Fibro-myomata.—Dr. Chalmers: Gangrene of the Vulva.

Thursday, April 23.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Surgical Consultations, 1.30 P.M.

Charing-cross Hospital.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2.30 P.M.

Royal Institution.—3 P.M. Prof. Tyndall: Natural Forces and Energies.

The Parkes Museum of Hygiene.—8 P.M. Sir Spencer Wells, Bart.: Cremation.

Friday, April 24.

St. George's Hospital.—Ophthalmic Operations, 1.30 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 2 P.M.

Quekett Microscopical Club.—8 P.M. Papers by Dr. Burch and Mr. F. Cheshire.

Clinical Society of London.—8.30 P.M. Dr. Sidney Phillips: A case of Sporadic Cretinism.—Mr. Walsham: Ligature of the External Iliac Artery, with two Kangaroo-tail Ligatures and Division of the Artery between them, suppuration of the sac, ultimate recovery.—Dr. Dickinson and Mr. Rouse: A case of Renal Lithotomy.—Dr. Hadden: A case of Obstruction of Arteries and Veins extending over many years.—Mr. J. R. Lunn: Four cases of Osteitis Deformans (living specimens).—Mr. R. W. Parker: A case of Thyrotomy with Preservation of Voice (living specimen).—Dr. Stephen Mackenzie: (1) A case of Osteitis Deformans; (2) A case of Hereditary Multiple Tumours (living specimens).

Royal Institution.—9 P.M. Mr. W. Carruthers: British Fossil Cycads.

Saturday, April 25.

King's College Hospital.—Operations, 1 P.M.

Royal Free Hospital.—Operations, 2 P.M.

Royal Institution.—3 P.M. Mr. W. Carruthers: Fir-trees and their Allies.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

WAR WITH NATURE.

AT the commencement of the war in the Soudan we called attention to the uselessness of a contemplated occupation of the Soudan by Europeans. In the House of Commons on Monday, the 13th, Lord Randolph Churchill repeated this fact, stating that from a personal visit he had gathered that our troops were suffering terribly from the effects of the climate. This will prove *our* conqueror, even if we should succeed in "smashing the Mahdi."

Publicity.—The discreditable practice is one with which the corporations alone can effectually deal.

"OVERWORK IN TELEGRAPH OFFICES."

To the Editor of THE LANCET.

SIR,—I read with interest an annotation under the above heading in your issue of the 28th ult.

A few days before the late Postmaster-General expired I had written to him stating the case of my daughter, who was in the service in a provincial city, and drawing his attention to the hours of labour at that office—9 A.M. to 5 P.M. or 10 A.M. to 6 P.M., with only an uncertain fifteen minutes between those hours for lavatory and a scrap refreshment, and in the twelve months a fortnight's holiday. She was admitted into the service after receiving a medical certificate of good health. Mental strain to excel in the various complicated systems continuously cropping up in the service often caused complainings of debility. To have gone on sick-leave meant half salary, with no private resources to fall back upon; so she continued at work till ultimately she broke down, and for weeks lay between life and death. She is still in the service, but suffers much from impaired health and broken constitution. Some initiatory step was the result of my letter to Mr. Fawcett, and inquiries were at once instituted in the office at which my daughter was employed. I did not hear officially on the matter, and suppose the sudden death of the Postmaster-General broke the thread of my appeal for amelioration of the rule in that office—fifteen minutes for hasty refreshment and half salary when stricken down, or when rest is deemed a necessity to put off a total breakdown. I am, Sir, yours obediently,

FATHER.

April 4th, 1885.

"CONSCIENCE MONEY."

To the Editor of THE LANCET.

SIR,—The following is probably a rare, if not a unique, experience in these hard times. My partner amongst his letters found an envelope with a five-pound note enclosed in a sheet of writing-paper, on which was written, "Conscience Money." There were some initials in the corner of the paper, but they were so minute that they could not be deciphered even under a "high power."

I am, Sir, yours truly,

Fyfield, near Andover, April 11th, 1885. W. J. H. LUSH, M.D.

PUBLIC GARDENS AND PLANTATIONS OF JAMAICA.

THE annual report of the public gardens and plantations for the year 1884 has just been issued by Mr. Morris, the director of these plantations. It contains much valuable information, and shows the state of the experimental cinchona plantations carried on by Government for the purpose of the scientific culture of different species of cinchona and for supplying seeds, seedlings, and plants to private planters. As regards the present position of cinchona cultivation, the market would appear to be in a very depressed state, and the prospects of the cinchona planter not of a very encouraging character. It should be remembered, however, that the whole history of the quinine market is one of numerous fluctuations.

Qualified Assistant.—There are legal points to be considered by the practitioner, though they are more or less at the discretion of the presiding judge, who might see fit to dispense with the presence of the qualified assistant as a witness.

P. W. M.—The paper is marked for early insertion.

"AN EL DORADO FOR MEDICAL MEN."

To the Editor of THE LANCET.

SIR,—We of the profession here derived considerable amusement from the perusal of the sensational annotation with the above heading, which appeared in your issue of Jan. 24th. But in case the brilliant and dazzling array of fees therein contained should tempt some rash and adventurous spirits to plunge into the unknown wilds of the Argentine Republic in search of patients, practice, and *pesos* (dollars), perhaps you will allow me to correct some of these figures and to sound a slight note of warning. The only correct figures are 8*s.* for a consultation at the doctor's house, 16*s.* for a visit to the patient's house, and £20 for a confinement without operations (midwifery fees are high, because midwives are universally employed, and but a small proportion of cases are attended by doctors). The other tremendous fees tabulated I happen to know were actually paid, but it was in solitary and particular cases only.

An item also much exaggerated is that of £20 and upwards for consultation, the consultation fee fixed by law being £4 for each doctor at each consultation. As the people here are more nervous and apprehensive, consultations are much more indulged in than at home. In fact, the ordinary routine work of the general practitioner is so badly paid for that without consultation it would be difficult for the doctor to make both ends meet. The man who is thoroughly appreciated here and whose work is always well paid, is the skilled operating surgeon; £100 would be an ordinary tracheotomy fee, and £150 or £200 the fee for excision of the breast. Eye specialists also command good practice and good fees.

Per contra, we have the expense of living, which is very high in this city. A small house in the centre will cost from £250 to £300 per annum, and a couple of servants another £100; food is cheap, but everything else extremely dear. Again, there is a large and flourishing medical school here which turns out some forty or fifty medical men every year, and, although the native doctors are uniformly most courteous and tolerant, still they invariably call in their own set to consultations, except the family insist on the presence of a foreign doctor. Besides this, a thorough knowledge of Spanish is necessary before starting, and the candidate must have a university degree, M.B. or M.D., as the Faculty here will not accept the ordinary double qualification; diplomas must also be revised by the Argentine Consul in London before you come out.

Fulfilling all these conditions, and with a good medical education to fall back upon, a steady English gentleman will find here a hearty welcome, a hospitable land, and a warm-hearted and generous people. But let him beware of the thousand pound gentlemen, and let him be cautious about taking gratuitous advice from even such a highly respectable journal as the *South American Journal*. Apologising for this lengthy communication, I remain, Sir, yours very truly,

VERITAS.

Buenos Ayres, Feb. 23th, 1885.

M.B.—If a police-surgeon is called to attend a prisoner at the instance of the police, he is clearly justified in demanding the usual fee. If his advice is sought at the instance of the prisoner, he has no legal claim against the authorities. It behoves a medical man to satisfy himself of the facts before rendering professional aid to a person in charge of the police.

IRON HOUSES.

To the Editor of THE LANCET.

SIR,—I should be obliged if any of your readers could give me any definite information with regard to iron houses from a hygienic point of view. The advantages are obvious; durability, economy, rapidity of erection, and portability, if I may use such a term concerning what is commonly considered a fixture, it being understood that the houses meant are of the cottage or bungalow type and of small size. Theoretically, of course, a residence with iron shell is not healthy, being hotter in summer and colder in winter than brick or stone; *per contra*, no damp or wind can penetrate. Again, are there means of avoiding the extremes of temperature induced by the non-conductor, such as felt or wood lining, or coating of composition, or the like? Many such additions are recommended by builders, but are they really trustworthy? Some practical hints from men who have lived in these houses will be useful to myself, and probably others. I am, Sir, yours faithfully,

COUNT.

April 7th, 1885.

PROFESSIONAL EDUCATION IN CUBA.

THE condition of science and education generally in Cuba is, according to the *Eco Cientifico de Las Villas*, most flourishing. All the faculties exist in the University, and studies can be carried on there in all branches up to the degree of Doctor. Each province has an institution for secondary education. The clinical and obstetrical departments of the hospitals are most satisfactory, and there are numerous practitioners of ability. Surgery has of late made rapid strides, all the most serious operations being now skilfully performed on the island. There are also numerous scientific and professional societies in a flourishing state.

A. K. C.—1. The charges appear perfectly reasonable.—2. Whether the result is to be regarded as quite satisfactory is a question which must depend upon the whole of the circumstances of the case, and these are not given.

THE BRUSSELS DEGREE.

To the Editor of THE LANCET.

SIR,—The M.D. degree is now so frequently sought by British practitioners, owing to the close regulations in regard to residence in force at our English and Scotch universities, that I am induced to give a short account of the last examination.

As is generally known, English medical men have the privilege, on presentation of their diplomas, of taking the three "Doctorates" at once, instead of at a year's interval between each. Candidates must be prepared to spend a fortnight, or even more, from the Saturday specified, in Brussels, although sometimes ten days are sufficient. The time may be shortened by deferring arrival until Monday or Tuesday, if special leave be obtained. There were sixteen candidates on the last occasion, all English. Of these, five were rejected at the first Doctorate, and one each at the second and third; so that nine, or little more than one-half, passed for the complete degree. This is about the usual average of late years. Probably two-thirds of the candidates were recently qualified; the rest had been in practice for some years.

The examination is entirely *vivâ voce*, unless by special arrangement. All the candidates are usually present in the room, although four only are taken on one evening. A little knowledge of French is helpful, although an interpreter is provided.

The First Doctorate is by far the hardest of the three, and will, in my judgment, for thoroughness and fairness compare well with most English examinations. Medicine, Therapeutics, Pathology, and Mental Diseases each occupy a quarter of an hour. As a rule, a subject—e.g., Pleuro-pneumonia, Dysentery, "Chronic Myelitis," Cancer of the Stomach, &c.—is taken, and the candidate is kept on that subject during the time specified, unless he shows marked ignorance, when a second subject is given him. One is expected to expound in detail the symptoms and course of the disease, "as if you were giving a lecture," and the causes for the various phenomena. "Go on," "And then?" and "Why?" are repeated at frequent intervals.

In Therapeutics also the test is a thorough one. The examiner, who is very gentlemanly in his manner, expects a full knowledge of the physiological action of the better known drugs, is especially particular as to the *modus operandi* of purgatives, diuretics, &c.; he is also well acquainted with recent discoveries and views, and asks often the properties of drugs which are only to be found in our most recent text-books, such as cocaine, nitro-glycerine, &c. Such a work as Mitchell Bruce's Materia Medica (Cassell) is, however, quite sufficient.

Pathology is the rock on which most make shipwreck at the First Doctorate. It is no secret that this examiner is the terror of candidates, partly because of the minute knowledge of morbid anatomy and of microscopic work he requires, and partly because of his manner of examining. Mere cramming of the subject is quite useless. Such a book as Green's Pathology must be studied repeatedly, until the various morbid appearances are graphically present to the mind's eye of the candidate, and he must not be put to confusion by rapid cross-questioning and frowning looks. Parasites form also a favourite topic.

Mental Diseases are but lightly treated. The examiner for this subject asks also on general medical science, methods of diagnosis, &c. On the whole, the First Doctorate is a fair, though rather difficult, test, at which many men fail on their first attempt.

The Second Doctorate embraces Surgery, Medical Jurisprudence, Midwifery, and Hygiene. The first of these is not generally difficult; it is, however, unequal. There is little or no surgical pathology; general and regional surgery must be familiar to the candidate. Midwifery is thoroughly, and rather scientifically, entered into. Besides one of our best text-books, some acquaintance with a French manual would be helpful. Such questions as the different kinds of fœtal movements, external and internal ballottement, &c., are required in some detail, and the variations in the fœtal pulse according to sex is a favourite point. For Medical Jurisprudence and Hygiene it is almost impossible to prepare. A general acquaintance with these subjects is undoubtedly required; but the questions asked must be answered by common sense. Cremation, the general effects of climate in their widest sense, the effects of wind on soil, the period of incapacity for work after injury, &c., are not subjects to be found in English text-books, and, as a fact, common sense and a little medical experience suffice to answer the questions.

The Third Doctorate is entirely practical. Clinical Surgery is under M. De Roubaix, Surgeon to the King, a veteran whose eye and hand are quick and steady as ever in his art. He practises antiseptics in a modified form. Both in Surgery and Medicine cases have to be examined in the hospitals, two in each subject. There is no difficulty in this to men accustomed to practise. Little of the minuter methods of diagnosis is required. Operative Surgery is rather hard. Three operations have to be performed: one ligature of artery, such as the radial, femoral, or lingual; one amputation of finger, or a Chopart, &c.; and, lastly, catheterism, castration, resection of middle third of clavicle or of part of a rib. Dissections are also required; and here a pretty accurate knowledge of the regions is needful—the cutaneous nerves, order of tendons, especially the lymphatic glands and vessels, also cranial nerves, &c. The severity of the recent anatomical test was unlooked for by most of the candidates. Practical Midwifery with the mannequin is fairly carried out. Some ordinary facility in operations is required.

Thus it will be seen that a fair all-round test is applied. At the same time it is the Medicine and Pathology examiners who reject the men. Those who pass MM. Crocq and Wehenkel will most often somehow get through the remaining Doctorates. Many men go over to Brussels with little idea of what they will find; and I heard bitter complaints from some who had put faith in advertisements which had appeared in England.

I hope the day is not distant when one or more of our own universities will give to English students an examination something like this. Let it aim at a high standard in all branches, let the fee be a substantial one, but let it not require that one condition which to the busy practitioner is unattainable—residence. Is it no loss to the British Universities (if they be deaf to any higher motive) that so large a number of our own men, and men not slothful or ignorant of their profession, should be driven to spend their money for a foreign degree?

I am, Sir, yours faithfully,

Finsbury-circus, April 4th, 1885. HINGSTON FOX.

*** We are frequently asked about the examination for the degree of Brussels. The above letter will supply the information desired. It cannot be considered that the ordeal quite realises that which an examination for a degree should be. There is no examination in Arts; none in Anatomy and Physiology proper. There is no written examination, and no thesis. Even in Medicine, which seems to be the subject in which the examination is most severe, it appears to be by no means exacting.—ED. L.

Virtus vincit invidiam.—Our correspondent is thanked for his letter; but we think it would be better to postpone any remarks on the subject for a short time, till we see what steps are taken to remedy the grievance.

Dr. Horace Swete's (Worcester) letter will appear next week.

"IMPROVED FRACTURE BOX."

To the Editor of THE LANCET.

SIR,—In your issue of the 11th inst. a special form of splint is described by Mr. Foley, Medical Officer for Midleton Hospital, as a new invention. Permit me to state that I have used a splint similar to his for two years, but with an addition, which I consider important—viz., the use of plaster straps, attached to the fractured limb, and to the end of the splints, to act as a counter-extension, extension being made by plasters, below the seat of fracture, and attached to a ratchet at the lower end of the splints. The apparatus is simply box splints, with the addition of plasters and a ratchet for extension. In shape my apparatus is similar to Mr. Foley's, without having perforations in the pieces, which is an improvement. My idea was to have a box splint, able to keep up extension and counter-extension, in oblique fractures of the leg, and for compound fractures. At the time I carried out my ideas I mentioned the fact to Professor Chiene of Edinburgh, who may, however, have forgotten about the matter.

I am, Sir, yours faithfully,

Fife, April 13th, 1885. T. GOODALL NASMYTH, M.B., C.M.

THE BIRTH-RATE OF ILLEGITIMATES IN PRAGUE.

AMONG 7031 births in Prague there are 3762 legitimate and 3329 illegitimate. It is a noteworthy fact that the death-rate among the illegitimate does not greatly exceed that which prevails among the legitimate.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—Allow me to point out a slight clerical error in my letter of the 4th inst. As it stands in your issue of the 11th inst. I am made to say that the Lieut.-Governor of Guernsey, the bailiff of Guernsey, the chief constable of Guernsey, *and* Dr. Le Page *each* received a copy of the *Journal*. The clause should run:—"and the following officials: the *Lieut.-Governor of Guernsey*, the bailiff of Guernsey, the chief constable of Guernsey. Dr. Le Page received a copy of the *Journal*." I am anxious to prevent any possible misunderstanding on this point.

I am, Sir, your obedient servant,

Guernsey, April 13th, 1885. J. AIKMAN.

DISINFECTING CHAMBERS.

To the Editor of THE LANCET.

SIR,—I shall be glad if any of your readers will be good enough to inform me which are the best disinfecting chambers now in use and where to be seen. I am, Sir, yours faithfully,

April 11th, 1885. MEDICAL OFFICER OF HEALTH.

HAMILTON COUNTY, KANSAS.

A CORRESPONDENT at Aubery, Hamilton County, Kansas, writes to us pointing out the advantages which the county affords as a place of residence for dipsomaniacs who are wishful to get rid of their craving. It is against the law of Kansas to sell, or for the railways to carry, any intoxicating liquor, of which, our correspondent states, there is not a pailful in the county. Land is cheap, and there are many methods of employing capital, in the raising of stock, &c.

Haslingden.—We have no further information on the subject.

Mars.—The question was answered in our issue of March 21st, p. 547.

A WARNING.

To the Editor of THE LANCET.

SIR,—I learn that an impostor is going about the country bearing a *card and recommendation from me. He has victimised* members of the profession by representing himself as a doctor's son. Let me warn your readers against anyone showing a card in the name of

Southborough, April 13th, 1885. E. PAGET THURSTAN, M.D.Cantab.

To the Editor of THE LANCET.

SIR,—I should like to warn my professional brethren against an impostor who says he is the son of an Indian surgeon. He is about 5 ft. 8 in., thin, with light-brown hair and mutton-chop whiskers. He professes great piety, and cannot get a situation as photographic operator as he refuses to work on Sunday. I unfortunately *gave him a frock-coat and some blue and white shirts with turn-down* collars, and entrusted him with some money, which he stole, together with an overcoat which he begged another person to lend him. He imposed on me by means of a visiting-card of Dr. Thurstan, who knows nothing of him. I am, Sir, yours truly,

Woolwich, April 14th, 1885. T. MAXWELL.

THE PARASITIC NATURE OF MELANOSIS.

To the Editor of THE LANCET.

SIR,—A reference to the "Medical Digest," Section 1670 : 3, will show that in your pages in 1867 the experiments of M. Gorgon upon the inoculability of melanosis were commented upon. Since that time, until your note upon M. Bard's discovery in THE LANCET of April 4th, p. 633, no observations upon the subject have caught my attention.

I am, Sir, yours obediently,

South Hampstead, April 4th, 1885. RICHARD NEALE, M.D.Lond.

GLYCERINUM ACIDI CARBOLICI IN DIABETES MELLITUS.

To the Editor of THE LANCET.

SIR,—A patient of mine suffering from diabetes mellitus in which the thirst was very excessive, I tried every known remedy to alleviate it without effect. I ordered glycerinum acidi carbolici in five-minim doses, and it relieved the patient at once. At present he is in good health, the urine being almost free from sugar.—Yours faithfully,

Rathfriland, March 31st, 1885. J. MCAVOY, M.D.

"AN OLD MEDAL."

To the Editor of THE LANCET.

SIR,—Is it not probable that the medal referred to by your correspondent, "M. U.," was struck previously to the enclosure of the gardens, which, to avoid inconvenience, was postponed until a sufficient number were circulated? I am, Sir, yours faithfully,

April 14th, 1885. M.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Surgeon-General Stewart; Mr. Henry Lee, London; Mr. Reginald Harrison, Liverpool; Dr. Geo. Oliver, Harrogate; Dr. Eben. Watson, Glasgow; Dr. Farquharson, London; Dr. Taylor, Anerley; Messrs. Cassell and Co., London; Mr. Blok, London; Mr. Brown, Cardiff; Dr. Joseph Bagdanik, Biala; Mr. E. Shoesmith, Rochdale; Mr. Radley, London; Mr. J. G. Thomson; Mr. Rawlings, London; Mr. Carmalt Jones, London; Mr. Mumford; Dr. H. Swete, Worcester; Mr. Wale, Maidstone; Mr. T. G. Nasmyth, Foulford; Dr. Thurstan, Southborough; Mr. Blackett, London; Mr. Aikman, Guernsey; Mr. J. W. Beck, London; Mr. A. J. Cook, London; Mr. A. G. Auld, Wick; Mr. W. C. Steele, London; Mr. J. N. Cook, London; Mr. H. B. Hewetson, Leeds; Mr. W. G. Lacy, London; Dr. Casey, New Windsor; Mr. C. Morris, Chester-le-Street; Mr. Drew, Wellington, N.Z.; Dr. Acland, Oxford; Dr. Sinclair, Dundee; Mr. N. C. Dobson, Clifton; Dr. Brett, Watford; Dr. Althaus, London; Deputy Surgeon-General Fowler, Bedford; Mr. Berdoe, London; Mr. Haggard; Mr. C. N. Williamson, London; Mr. Hutchinson; Mrs. Bourchier, Sheffield; Mr. Edwards, Chester; Mr. Cardew, Teignmouth; Messrs. Brown, Davis, and Co., Glasgow; Dr. S. C. Griffith, London; Mr. Maythorn, Biggleswade; Mr. Hulme, Birmingham; Mr. Selwood, Winchester; Dr. Weaver, *Southport; Mr. Spitzty, Canonbury; Messrs. Norman and Co.*, Cheltenham; Mr. Twyford, Hanley; Mr. Bigg, London; Dr. Chafer, California; Dr. Hickie, Birmingham; Messrs. Grinley and Co., London; Mr. Jenne, Halesowen; Mr. Hill, Clifton; Messrs. Riddle and Co., London; Mr. Beloe, King's Lynn; Mr. Clark, Bristol; Mr. Heywood, Manchester; Messrs. Whitehead and Co., Manchester; Mr. Crewt, Truro; Messrs. Wilson and Stockholme, Bury; Mr. Negan, Canterbury; Mr. Oldham, Monsall; Dr. Burham, Surat; Messrs. Clay and Sons, Manchester; Mr. Carmody; Mr. Gravatt; Dr. Buchanan, Glasgow; Miss Smith, Plymouth; Mr. Beckton, London; Mr. Giles, London; Messrs. Kegan Paul and Co., London; Mr. Birchall, Liverpool; Mr. Sloane, Bradford; Mr. Faberner, Wigan; Mr. Sharpe, Walsall; Mr. Bluett, Brighton; Mr. Hodgson, London; Mr. Freeman, London; Mr. Paul, Liverpool; Mr. Sargent, London; Messrs. Bell and Co.; Mr. Craske; Mr. Hammond, Clifton; Messrs. Shanks and Co., London; Dr. Money, Rickmansworth; Messrs. Hawkes and Co., *London; Mrs. Tillett; Quæstor; Mechanic; Rest;* H. O.; Mutare Sperno; Mars; An M.D. of New York; Haslingden; J. G.; The Matron, Eston; W. C., Bath; Sanitas, Hyde; G. S. D.

LETTERS, *each with enclosure*, are also acknowledged from—Mr. Hind; Mr. White, Bayswater; Mr. Cane; Mr. Peirson, Ipswich; Mr. Deane, Cawnpore; Dr. Hawkin, Manchester; Mr. Bird; Dr. Adam, West Malling; Mr. Vines, Shepton Mallet; Messrs. Dickson and Russell, Edinburgh; Mr. Kinder, Leicester; Mr. Reynolds, Derby; Mr. Young, Hawkhurst; Mr. Watson, Glasgow; Mr. Brown, Pimlico; Mr. J. Barker, London; Mr. Skinner, Winchelsea; Mr. Cotterell, Bicester; Mr. Stack, Dublin; Mr. Parker, Sidmouth; Mr. Micharlescue, New York; Miss Wade, Chorley; Mr. Symons, Dumfries; Mr. Dolby, Cannock; Mr. Morris, Swansea; Mr. Duke, Freshwater; Mr. Hunter, Turnham-green; Miss Bretherton, Preston; Mr. Sloane, Bradford; Mr. Bridgman, Barnstaple; Mr. Eberle, Thirsk; Dr. Harding, Wigglesea; Mr. Smallman; Mr. Shepherd, Putney; Mr. Stilliard, Birmingham; Dr. Gledhill; Z., Newcastle-on-Tyne; Medicus, Halifax; G., Southport; Surgeon, Buckfastleigh; Delta, London; Lady Superintendent, Bangor; M.D., Wigan; F.S.A., Wye; Omega, Pontnewydd; M.B.; Medicus, Glasgow; Beta, Frizington; T. W. L. B., Great Yarmouth; Boon, Hulme; C. F. D., Bury; H. O. M.; Medicus, Leicester; D., Cradley Heath; H. B. G.; Drax, Dublin; The Secretary, Carmarthen; W. G., London; M.D., London; Physician, St. Lawrence; B. B.; Medicus, St. John's Wood.

Scotsman, Aberdeen Herald, Hertfordshire Mercury, Burton Advertiser, Southport Visitor, Stirling Reporter, &c., have been received.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months £0 16 3
To CHINA AND INDIA	One Year	1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES	Ditto	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Croonian Lectures

ON THE

HYGIENIC AND CLIMATIC TREATMENT OF CHRONIC PULMONARY PHTHISIS.

Delivered at the Royal College of Physicians,

BY HERMANN WEBER, M.D.,
PHYSICIAN TO THE GERMAN HOSPITAL.

LECTURE III.

(Concluded from page 695.)

Duration of stay, and season of the year.—The time during which an invalid ought to stay in elevated regions varies greatly, according to the nature of the case, from four and six months to as many years, and general rules can scarcely be laid down. He ought to remain until he is cured, or until it is seen that the climate does not suit him. An additional advantage of these climates is that the majority of patients can remain throughout a whole year, with occasional changes to allied, not to distant, localities. The winter season is the best in the Alps; spring is the time of general melting of the snow, and soil and air are damper than in winter, so there is more risk of chills and possibly of microbic infection than in winter, but this risk is not greater than in lower regions, where the air at the same time is more relaxing. The descent to lower regions ought therefore not to be the rule, as it is at present, but the exception, and this only after careful consideration, and with all due precautions as to travelling, selection of locality, rooms, &c. In summer it is desirable to select mountain places which are rich in pine forests, in order to have shade from the sun and the additional benefit of the exhalation of the pines. The first part of autumn is very good, while the second forms a transition stage to winter, and is often unfriendly. Where it can be arranged, the stay in the European Alps ought to commence in August or the beginning of September, in order that the acclimatisation can take place before the changeable transition stage begins.

You will ask me which elevation is required to bestow on a cality the character of a mountain climate. This varies reatly according to the degree of latitude, distance from ne sea, and other circumstances on which I cannot enter at resent. The character of the vegetation is to some degree good criterion. In the flat regions of Northern Germany an elevation of 1500 feet is sufficient to produce a vegetation which somewhat resembles that of the Swiss Alps at an elevation of nearly 5000 feet, and of the Peruvian Andes at 10,000 or 11,000. The isothermal lines are likewise a help in this question. We may perhaps say, but only roughly, that in Europe north of 50° an elevation of about 1600 feet has already some characteristics of mountain climates; while between 50° and 48° latitude about 1700 feet to 2500 feet are required; and between 47° and 46° latitude from 3000 to 5000 feet. I need, however, scarcely tell you that I think all the climatic characters of a mountainous region in North Germany or Northern France at an elevation of 1600 to 2000 feet are the same as those of 5000 or 6000 feet in the Swiss Alps. The average air temperatures may be similar, and also the time during which the ground is covered with snow, but the rarefaction of the air must be less great at the lower elevations. The air is heavier, the light and sun-heat are less intense, and the moisture is mostly greater. About the microbes I am not yet sure; their distribution is likely to be unequal; but where there are only few human habitations, and few sources of organic decay and putrefaction, where the soil is dry and especially where it consists of granite and gneiss, with absence of stagnating water, there the microbe element will probably be scantily represented.

From what I have said you will expect me to recommend altitude climates in hereditary and acquired tendency to phthisis, and especially in cases with imperfect expansion of the thorax and the so-called "phthisical habitus"; and further, in all conditions comprised by the term phthisis, excepting those which I must describe as non-suitable viz., (1) consumptive patients, who belong to what I have termed the erethic constitution, whether the affection is early or advanced; (2) phthisis in a very advanced stage; (3) phthisis complicated with emphysema; (4) phthisis complicated with albuminuria; (5) phthisis complicated with disease of the heart; (6) phthisis with ulceration of the larynx; (7) phthisis with rapid progress and constant pyrexia; (8) phthisis with great loss of substance; (9) phthisis with considerable empyema; (10) phthisis in persons who cannot sleep or eat in high elevations, or who feel constantly cold. Some of the conditions are not permanent, but only temporary and removable obstacles. Tendency to hæmoptysis was formerly regarded as forbidding mountain climates, but experience has shown that this is incorrect; that, in fact, hæmoptysis occurs much less frequently in high than in low regions, and is often prevented and checked by a stay in high regions (Archibald Smith, Brehmer, Spengler, Unger, Dettweiler, C. T. Williams, Denison, Solly, Ruedi, Peters, and Hermann Weber).

After having discussed the general characters and influence of the climates of elevated regions, I must limit myself to a few remarks only on the principal health resorts, as time compels me to do so; and as there already exist numerous descriptions in the English language by professional and non-professional authors, I need not tell you that the difference between the different localities included in this class of climates is very great, and is only yet partially known and appreciated; that even in the same Alpine valley, and in the same place, there are great differences between different situations, and that the climate of the same place is by no means uniform in different years.

We naturally begin with the Swiss Alps, as they are nearest to us, and with Davos Platz about 5100 feet above the sea level, as it was the first place resorted to just twenty years ago, when two patients migrated there from Gorbesdorf, Dr. Unger and Mr. Richter, who there regained their health and are still living at Davos in active occupation. They were encouraged to give a prolonged trial to the place by Dr. Spengler, who had already written on the absence of scrofula and phthisis in the Davos Valley. As I had been on the look-out for a suitable place in the Alps for some years previously, in consequence of some encouraging experiences which, I might say, accident had thrown in my way, I soon afterwards began to send patients there. When I first directed attention to Davos Platz in 1867 it was still a charming primitive Swiss village; now numerous large and small hotels and villas stretch along the high road for more than a mile, and Davos Dörfli, a little higher up in the valley, may almost be considered as a suburb of Davos Platz. Waters, Spengler, Frankland, Unger, Clifford Allbutt, Addington Symonds, C. T. Williams, Burney Yeo, Peters, Marcet, Otter, Jaccoud, Sée, Symes Thompson, and others have amply described the peculiarities of Davos. The presence of good physicians, the more and more improving arrangements in the hotels, including sunny terraces and verandahs, the means of varied exercise and amusement, the comparative nearness to the railway, a good road thence (from Landquart or Chur) to Davos without an intervening high pass, are accessory, though very important, to the general climatic characters of Davos Platz and Dörfli. A drawback is that its reputation has of late years increased so rapidly that too many, frequently ill-suited, cases are sent to Davos; that the number and size of the hotels and health establishments increase at an alarming rate, so that there is actual danger that Davos may be ruined by its own original advantages; *for purity or aseptic quality of the air is incompatible with the crowding together of a large number of invalids.* Mr. J. Addington Symonds, the author of "Davos in Winter," has written on this subject in the *Pall Mall Gazette* of Jan. 14th, 1882; and I have likewise already mentioned this matter in a paper on Climate and Health-resorts in the "Book of Health." If Davos were to be ruined, the calamity would not be confined to the inhabitants of the valley, but would be shared by many invalids all over Europe.

Lower down in the Davos Valley, at Davos Frauenkirch, a small hotel offers fair accommodation to a limited number of invalids; and further down, but high above the bottom of the valley of the Landwasser on the sunny southern slope of the Rothornstock, lies Wiesen, of about 4770 feet of which Dr. Tucker Wise has given an attractive description. It is well sheltered from N. and N.E., but is rather more exposed to S.W. wind than Davos, and the snow does not lie quite so long. The hotels and the social attractions are not so advanced as those at Davos, but the stay is less expensive and under the guidance of Dr. Buol, an intelligent Swiss doctor, who is a licentiate of the London College of Physicians, results can be obtained in suitable cases, even with limited arrangements.

The Upper Engadine is a fair rival to the valley of Davos, and the village of St. Moritz, about 6000 feet above sea level and 280 feet above the lake, with the well-known Kulm Hotel and the houses of Kaspar Badrutt, represents the Davos Platz of the neighbouring valley. St. Moritz has been so well described by Dr. Burney Yeo, Mr. Lionel Tollemache, Drs. Ludwig, Biermann, and many others, that I must confine myself to a very few remarks. Davos is somewhat more sheltered and is slightly warmer than St. Moritz, and is nearer to the last railway station for those coming direct from England or the North. St. Moritz lies 900 feet higher, has the advantage of the snow somewhat longer. has decidedly more wind according to the observations of Mr. Waters, has a skating rink and a good lawn tenis court in the immediate neighbourhood of the hotel, and more opportunities for exercise. On the whole, Davos has some advantages for more serious invalids; St. Moritz for hardier cases. The best sites in the Upper Engadine would probably be found in the neighbourhood of .Pontresina on the south western slopes of the Muraigl on the Munt Della Bescha; they would have the largest share of sunshine during the shortest days of the winter, would be in the immediate neighbourhood of pine and larch forests, and out of the way of the Maloija wind; but the hotel proprietors of Pontresina are as yet hostile to the scheme of a winter cure, fearing that their summer guests would leave them if they were to open that favourite spot for the treatment of phthisis. They are apparently strong contagionists. But there are sites, for instance, near Acla, about 6000 feet above sea level, to the right of the road from Pontresi na to Samaden, over a mile from the former, where one or two health establishments might be placed without prejudice to the visitors of Pontresina.

Samaden has been for many years used by some consumptive patients as a winter resort, and the excellent fare and service at the Hotel Bernina make to some degree good what the absence of open and covered verandahs and balconies and terraces leave to be desired. Above Silvaplana and Campfer, on the southern slopes of the Piz d'Albana and Piz Valaschin, good sites could be found. The establishment of the Kursaal Maloja is rather exposed to wind, and not high enough above the upper end of the Lake of Sils to be perfectly free from damp and mist at all times of the year; but the Kursaal itself is dry, and the large corridors for indoor exercise, the arrangements for constant and abundant supply of warmed air to the rooms and passages, and the good cuisine make atonement for some defects in the position. Dr. Tucker Wise, who is the resident medical officer, has given an encouraging description of these arrangements; and such improvements as sheltered out-door seats and pavilions were in the course of erection when I was there on a visit during the autumn of 1884. Independently of permanent residence the Maloja Hotel can do good service as a place of transition—for instance, during the melting of the snow when out-door exercise is difficult. A few weeks at this place will occasionally be an advantage to visitors at St. Moritz or even Davos, as they can walk for hours every day in the well-aired corridors without exposure to draught or dampness. The localities mentioned, and Zuz in the Upper Engadine, are all the winter health-resorts in the High Alps which are open to us at present. There would be some satisfactory places in the Dolomites, as above Cortina, and perhaps San Martino di Castrozza and Campiglio, but there are no arrangements for the winter as yet.

In a much lower situation is St. Beatenberg, above Lake Thun (3766 feet), quite sheltered from the north and east, quite open to the south, and very sunny. It is only lately that the proprietors of the Kurhaus have commenced to keep the hotel open, and I cannot therefore speak of the results. The Hotel des Avants (3212 feet above sea level, and 2000 feet above the Lake of Geneva) has a very sunny situation, and is already out of the region of mists in winter. The arrangements of the hotel are good, but the snow does not lie so long as at Davos and St. Moritz; and although preferable in many ways to the lower localities on the lake, it is not as bracing as the health resorts in the Grisons. Seewis, (2986 feet), above the road from Landquart to Davos, has a cheerful sunny and sheltered situation. Such localities will probably, by degrees, take an important place as *intermediate health resorts* for intermediate cases; for such, to use an instance in which the usefulness of higher localities is doubtful, or in which they are certain to be unsuitable, where, however, a surrender to the low level places is undesirable; or as temporary places—viz., as steps to or from the higher health resorts. Seewis, for instance, is well adapted as a stepping-stone to Davos and St. Moritz. In order, however, to become really useful, they must, as Seewis has done, provide themselves with good resident medical men, as without this it would be wrong to entrust to them cases requiring special care.

I must now name two localities in Germany which deserve your attention, although I can mention them only in a cursory manner: these are Görbesdorf in Silesia, and Falkenstein in the Taunus. Görbesdorf, about 1740 feet above the sea level, is the cradle of the mountain health resorts, and of the hardening open-air treatment in Europe, with a judicious admixture of hydro-therapeutics. Dr. Hermann Brehmer has the merit of having introduced this combination in a systematic manner, coupled with the strict supervision of the patients, essential in the hygienic as well as therapeutic management. Brehmer's establishment lies in a beautiful park, with a pine-clad hill belonging to it, arranged for graduated climbing. The establishment is provided with covered walks of great length, and with a winter garden, suitably warmed and ventilated. Falkenstein, about 1500 feet above the sea level, has become, under the judicious as well as energetic guidance of Dr. Dettweiler, a health resort where not only many invalids have been improved and cured, but where they have learned how to manage themselves afterwards. The results obtained at this establishment show how much can be done in phthisis by carefully arranged hygienic management, even with imperfect climatic elements.

During the last few years several other establishments have been formed which are likely to become useful, and to lead to further imitation. Aussee, in Styria (2150 feet), St. Blasien (2500 feet), in the Black Forest, Reiboldsgrün (2257 feet), in the midst of a forest near the railway station of Auerbach, in Saxony, and Badenweiler (1380 feet), in a beautiful position on the south-western slopes of the Black Forest, deserve to be specially mentioned.

In Norway the Gausdal sanatorium, about 3000 feet above sea level and 2500 feet above Lake Mjosen, and twenty-four miles from Lillehammer, has been mentioned to me as a probable health resort for consumptives.

More important to us in the treatment of phthisis are the health resorts of America. In the Peruvian Andes and the Rocky Mountains of the United States they possess indeed an endless variety of mountain climates. Near the equator, elevations of 6000 and 8000 feet have winter temperatures similar to our summer temperatures, and we must go still higher to find localities suitable to the treatment of phthisis. But at greater distances from the equator we come at elevations of about 6000 or 7000 feet, to climates somewhat similar to those in the Alps at about 5000 to 6000 feet. In the neighbourhood of Jauja and Huancayo, at elevations varying from 8500 to 10,500 feet, several of my patients have recovered from rather advanced affections of phthisis, after I had learned the character of these climates, and had been encouraged in sending patients there by my late friend, Dr. Archibald Smith of Lima, whose papers on these subjects are well known to you. How different, however, these climates are from the Swiss Alps, you may see from the following statement of Archibald Smith:—"At Huancayo, 12° south latitude and 75° 12′ west longitude, the annual range of temperature in the shade may be taken as ranging from 8° or 9° to 14° R.; while at the cooler town of Jauja, with from 10,000 to 15,000 inhabitants, the range during one whole year has been observed not to exceed from 8° to 12° R., or from 50° to 59° or 60° F., with the sky always clear and sunny, and an atmosphere pure and bracing, which invites to outdoor exercise and enjoyment." From no other localities have I seen such good results as from Jauja; but also from Santa Fe de Bogota (about 10,000 feet), Quito (about 10,000 feet), La Paz (12,000 feet), and Cuzco (11,250 feet), I have occasionally received good reports. Areguipa, in Peru, 16° south latitude, has lately been recommended by Dr. Dixon Hunter, with an equable temperature, averaging about 65° summer and winter within the house and outside in the shade during the day. I have no doubt that this climate is infinitely better than many others, especially the hotter regions along the sea-shore, and that consumption can be cured there; but it is somewhat too warm.

The Rocky Mountains in the United States of America have only been used as health resorts in phthisis, so far as I know, during the last fifteen or sixteen years, and they seem to have met likewise at first with much opposition; at all events, during the last ten years the advice I have given to several American consumptive patients to settle at Denver or Colorado has been rather severely criticised by New York and Philadelphia doctors, especially in two cases of hæmoptic tendency, and yet these patients did well when they afterwards carried out the advice. Manitou springs (6315 ft.), Colorado springs (5775 ft.), and Denver (about 5000 ft.) are the best known localities, and have been repeatedly described by Drs. Denison and Solly; but numerous other resorts of the future are mentioned in Dr. Denison's instructive work on "The Rocky Mountains Health Resorts." Dr. Frankland has quite lately mentioned to me in this territory a locality which is likely to become an important health resort—Yellowstone National Park, accessible by the Northern Pacific Railway. It is situated on the eastern slopes of the Rocky Mountains, between 44° and 45° N. lat. "The park abounds in magnificent geyzers and boiling springs on a most gigantic scale, and there are plenty of mineral waters. The boiling water and steam might be made available for warming hotels, but there is also an abundance of wood fuel. There is so much room in Yellowstone that there need be no overcrowding, as at Davos."

Mexico, too, possesses good health-resorts, especially the town of Mexico and Puebla, about which the well-known works of Jourdanet and Guilbert contain valuable information.

The South African altitudes have been described by Symes Thompson and the late Harry Leech and by several non-professional writers—Trollope, E. F. Sandeman, and Otter. The most important health-resorts are contained in the Orange Free States, Griqualand West, and the Transvaal. Bloemfontein (4700 feet) is the best known place; but among others equally suitable are Christiania, Bloemshoff, Potchefstroom, Witwater Rand, Pretoria, Heidelberg, Utrecht, Standerton, and Wakkerstroom. Everywhere the climate is dry, and often in summer very hot, and in winter cold. I have seen some good from these localities, but the promise of "the absolutely perfect cure" held out many years ago by some inhabitants of the Free States has not been fulfilled. Whenever we recommend these regions we must bear in mind that a sea voyage and a long land journey are implied. Those who are good sailors will not regret the former, and the latter can be rendered beneficial if the invalid is not too weak and does not mind expense. The best mode to reach the high regions is still a well-supplied ox waggon from Graham's Town or Wynberg. "Waggon travelling with the traveller's own oxen," Mr. Otter justly says, "is very slow work, not averaging more than ten to twelve miles a day, but as such an expedition is only made for the sake of health, the rate of travelling is not material, and when once a traveller has got into a district which is suitable to him he is in no hurry to get out of it."

Many of the great mountain chains of Asia contain, no doubt, useful health resorts, but our dependable knowledge is almost confined to the Himalayas, which enclose, you may say, all varieties of climate, stretching along as they do for about 2000 miles, with an average width of 180 miles and elevations ranging from 1000 to 23,000. There are, besides, the Neilgherry range, the Pulneys, the Aravulli or Aravelli Mountains, the Vindhya range, the Western and Eastern Ghauts, and several other ranges. There are health resorts varying from 4000 to 8000 feet elevations. In considering these stations we must always bear in mind the nearness to the equator, and, further, that the peninsula is surrounded, excepting its broad base, by enormous masses of warm water. The periodical winds coming from these seas are saturated with vapour, which on reaching the cooler mountain ranges is partly deposited as rain. The emanations from the damp soil are probably laden with microbic life. The majority of the Indian Hill stations have therefore very different climatic conditions from those of the Peruvian Andes, the Rocky Mountains, and Swiss Alps. These circumstances may explain the contradictory views of Anglo-Indian medical men regarding the influence of their hill stations on phthisis. The carefully drawn up report, however, of Dr. Kellett on consumptive soldiers, who spent six months (April to November) at the convalescent station of Landour, shows results which are not unsatisfactory. Very different must be the climates on the northern slopes of the Himalayas, for the atmosphere before reaching them has lost the greater part of its moisture; on the southern slopes and highest ridges the climates must be drier and cooler, and very possibly Thibet (9000–11,000 feet) and Cashmere (5000–6000 feet) contain most healthy climates.

I had intended to survey with you, gentlemen, the climates of Nubia and Egypt, of Algiers, Italy, Spain, the Riviera, and south-west of France, of Australia, New Zealand, Madeira, Teneriffe, and the high seas, in their applicability to the treatment of phthisis; but time fails, and I hope you will pardon me for having spent so much time over other matters, and that you will not think I regard the regions which I pass over as useless. They have been so often and so well described by others as well as elsewhere by me, that my present omission can scarcely be regretted. Many of the localities included in these climates possess very useful qualities for the treatment of phthisis, and especially for those conditions and constitutions which are either temporarily or permanently debarred from the benefits of the altitude climates; but I regret to say that as yet the arrangements are nowhere perfectly satisfactory, even at the most favourite places, supplied with all the modern comforts, such as Cannes, Mentone, and San Remo; the majority of invalids are in the habit of acting almost independently of their medical advisers, and many perish who under strict guidance might have been saved. The personal character and professional superiority of a Dr. Frank, a Bright, a Charles, a Siordet, or of one of the other physicians practising there, may in some, even in many, cases exercise so powerful an influence as to command a willing obedience; but the whole system of this looseness of tie between doctor and consumptive patient is deplorable, and the results obtained are very inferior to those which might be obtained by judiciously arranged health establishments, under strict medical guidance in every point of general and personal hygiene. This, however, is by many invalids not yet regarded as the principal sphere of the physician's work, but more or less as everybody's business, for which no doctor is required, and which *each individual* must find out for himself.

I also regret very much that I cannot properly discuss the climates of Great Britain and Ireland. These islands contain on their different coasts and in their interior a great variety of climates, which have been well described by Sir J. Clark, Thorowgood, C. T. Williams, Tripe, Buchan, and others, and I have likewise given short sketches of them. With all the differences, great as they are, between the east and west, south-east and south-west coasts and the different inland localities, there are certain traits of character more or less common to all of them—viz., a high degree of humidity; greater warmth than is due to the geographical latitude; comparative equability with regard to seasons and periods of the day; an analogous degree of sunlessness and dulness of atmosphere; and considerable movement of the air, almost amounting to windiness. All these localities as a set-off possess hygienic arrangements which are superior to anything which is to be met with abroad, good food, and good accommodation; they are of easy access, and do not require a complete separation of the invalid from his family. The physiological influence on the constitution compared with foreign localities of a similar elevation may be designated as more or less tonic and health-giving, though not exhilarating, and as requiring a certain degree of energy and integrity of constitution. We possess in these islands good climates for preventive treatment; but we are not so well provided with localities assisting the treatment of developed phthisis, where the lungs and the constitution have partially lost their integrity and energy. We ought therefore to do everything to mend the defects of these our climates, and to render the good qualities available, and concentrate them if possible. Is this done at our health resorts for the treatment of phthisis? No, gentlemen, there are no such arrangements, or almost *none*, on the coasts of Devonshire, Hants, Sussex, and even the Isle of Wight, excepting the few sanatoria. Let us use our influence with our local professional brethren, who are neither deficient in knowledge nor in insight, and with the local proprietors and public, to obtain well-placed and well-arranged houses for the invalids, with suitable balconies on which light couches and shelters for open-air treatment can be placed, good large verandahs with movable glass doors; open and covered walks and winter gardens for exercise in windy and rainy weather; seats of different nature with turnable shelter; quadripartite glass-covered seats, like those at Hastings and St. Leonards, for which these places deserve commendation; walls for shelter from wind, and for reflection of the sun when it shines. We must induce our patients to place themselves under the entire control of their local doctors during their whole stay at one of our health resorts, and to learn that the guidance of the doctor is as important as the climate, and in many cases more so. By judicious management the doctor is often able to counteract the disadvantages of an indifferent climate and to bring into action all its good points, while without the guidance of an intelligent physician the natural and social attractions associated with a satisfactory climate may become sources of failure. There is no doubt in my mind that it would be a very great advantage to many invalids, especially those who are not very rich, if there were well-arranged health establishments under the supervision of good medical men, and that through them better results could be obtained from our home climates.

And once more, gentlemen, let me plead for the multiplication of small hospitals in good situations for the consumptive poor, such as I have sketched in the second lecture. You have always treated me with so much kindness and consideration since you have, so to say, adopted me as one of yourselves, that I am hopeful you will give your countenance to the plans I have suggested, and that through you they may lead to some good; then, gentlemen, the recollection of the hours which I have had the pleasure of spending with you in these lectures will belong to the brightest of my life.

CASE OF

BULLET WOUND (PENETRATING) OF THE ABDOMEN, WITH NUMEROUS PERFORATIONS OF THE INTESTINES, TREATED BY ABDOMINAL SECTION.

By THOMAS ANNANDALE, F.R.S.E.,
REGIUS PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF EDINBURGH.

A note of the following case will, I trust, be considered of general interest, and also of special interest in connexion with the recent discussion at the Royal Medical and Chirurgical Society.

T. R——, aged fifteen, was admitted to the Edinburgh Royal Infirmary, under my care, on the 9th of March of this year. One hour before admission he was standing in front of a companion at a distance of about two feet, when a loaded revolver which was in his companion's hand was accidentally discharged, and the bullet struck him in the abdomen. The patient did not fall, but, placing his hand on his abdomen, he walked about a hundred yards into the nearest house, where he was carefully attended to, made to lie down, and a temporary dressing applied over the wound. He was then conveyed to the infirmary, where he was at once seen by me. On inquiry it was ascertained that the bullet was conical in shape, a quarter of an inch in diameter at its base, and a little more than half an inch in length.

On admission there was slight general shock, and the patient complained of a little pain in the region of the abdomen and pelvis; but he was perfectly sensible, and gave an intelligent account of the accident. The clothes had been slightly disarranged in applying the dressing, but on examination there was seen to be a round hole in the double fold of the trousers in front, a similar hole through the flannel drawers, three distinct holes in the flannel shirt, which was in folds at this point, and, lastly, an opening in the flannel jacket worn next the skin. The textures for a short distance round the holes in the clothes were scorched. The temporary dressing having been removed, there was found a rounded opening in the abdominal wall, with ragged and scorched edges. The position of the wound was an inch and a half below and half an inch to the left of the umbilicus, its diameter being rather more than a quarter of an inch. A probe was carefully introduced into this wound, but, as its point became obstructed in the substance of the left rectus muscle, it was not further employed.

Operation.—Chloroform having been administered, an incision an inch and a half in length was made in a longitudinal direction, the bullet wound being included in its centre. The various tissues of the abdominal wall were carefully incised until the peritoneum was reached, when a narrow slit was seen in the latter membrane, and protruding through it there was a small piece of bruised omentum. This portion of omentum having been carefully pushed aside, a small knuckle of uninjured small intestine presented itself. The peritoneal wound having been slightly enlarged, another knuckle of small intestine with three distinct perforations in it at once protruded. Two of these openings were situated within a quarter of an inch of each other, the third at a distance of about an inch and a half from the others, on a different aspect of the gut. These three openings were stitched by means of a continuous suture of fine catgut after Lempert's method. Both the external and peritoneal wounds were now enlarged upwards and downwards, so as to allow a more complete search of the abdominal contents. When this was done a considerable amount of blood oozed up from the deeper part of the abdominal cavity, and on drawing aside some folds of intestine this hæmorrhage was seen to come from a large vein in the mesentery, which had been perforated by the bullet; this vein was seized and ligatured with catgut. A further examination of the intestines showed two more perforations in the small intestine—two in the descending colon, and two in the pelvic portion of the rectum; all these were sutured with catgut, as in the case of the first three wounds. A careful search did not discover the bullet, and no injury to the bones of the pelvis or to the vertebræ could be found. No extravasation of fæcal matter was observed, but there were several large clots of blood lying in the pelvis. During the operation the exposed intestines were carefully protected by towels soaked in a warm solution of corrosive sublimate (1 in 2000), and the whole cavity of the abdomen and pelvis having been sponged out with the same solution, the external wound was closed by means of deep and superficial sutures. After the operation the patient's pulse and strength were good, and a half-grain morphia suppository was introduced. In the evening the patient expressed himself as feeling comfortable, and his pulse remained good. Early on the following morning he became restless, complained of pain in the abdomen, and showed symptoms of exhaustion. He did not rally from this, but died about 12 o'clock, twenty-four hours after the accident.

Necropsy.—On opening the abdomen the intestines were seen to be much distended with gas, and the abdominal cavity contained about six ounces of brick-red serum. The first three wounds in the small intestine were situated about three feet and a quarter below the duodenum, and the other two wounds about two feet two inches below this point. The other wounds, as mentioned, were situated in the colon and pelvic part of the rectum. On passing a powerful stream of water through the intestines, they were found to be perfectly watertight, except that there was a slight leakage where the three intestinal perforations were situated close together. After considerable search the bullet was found lying on the right side of the pelvis immediately in front of the ischial spine. There was no injury to the bones or other structures.

Remarks.—This case is an interesting example of the deviation of a bullet, which, having entered the abdomen a little to the left of the middle line, perforated the small intestine, the descending colon, and the rectum, and, passing across, lodged low down in the right side of the pelvis. In order to diagnose the exact nature of the wound in this case, the principle of carefully incising the abdominal wall so as not to divide the peritoneum in the first instance was carried out, the bullet wound being kept in the centre of the incision as a guide. The gentle use of the probe gave no satisfactory result, except to prove that the bullet had passed into or through the rectus muscle. Had the wound been a non-penetrating one, my incision would have been attended with little risk, and it would in all probability have allowed the bullet to be detected and removed if it had lodged in the abdominal wall or any other accessible place. Although this case terminated fatally, the result of the operation, as proved by the post-mortem examination, is, I think, encouraging, and should another case of this kind come under my observation I would not hesitate to carry out the same principles of treatment. The very important and suggestive papers published in 1882 by the late Dr. Marion Sims, and the experiences and suggestions of distinguished American and other surgeons as the result of their large experience in military practice, form material and considerations worthy of the careful attention of all practical surgeons; and a study of them and of other facts in connexion with abdominal surgery, together with a knowledge of the fatality of these injuries, had prepared me to carry out active interference should a suitable case present itself. The complete staying of the hæmorrhage from the wounded mesenteric vein was an important result of the operation, and the entire absence of fæcal extravasation was also a most satisfactory point. The slight leakage which took place when a stream of water was passed with some force through the intestinal canal after death would not, I think, have led to any injurious effects during life. It can be readily understood that it was difficult, if not impossible, to ensure a perfectly aseptic condition in such a case; and I am inclined to think that drainage of the abdominal cavity would be advisable under similar circumstances. I did not employ drainage in my case because the abdominal cavity after the operation appeared to be perfectly free from blood-clots and fæcal or other extravasation; and I had hoped that the free use of the corrosive sublimate solution would have counteracted any septic mischief.

Edinburgh.

A CONTRIBUTION TO THE

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.

BY GEORGE OLIVER, M.D. LOND.

No. I.—THE TESTS FOR THE BILE SALTS, WITH DEMONSTRATION.

(Concluded from page 701.)

The peptone test solution.—Having got out the fact that bile salts when present in the urine precipitate a proteid from an acid solution, it was an easy matter to discover how to apply it as a practical test. On substituting for the acidified albuminous urine an acidulated antiseptic solution of peptone, I obtained a test solution much better in all respects, being readier and more delicate, and withal a preparation devoid of all objectionable qualities.[1]

The reaction.—When twenty minims of urine, containing bile salts in pathological quantity, are run into sixty minims of the test solution, an opalescence appears proportionate to the amount of the bile derivative. [Experiments shown.] It differs from all other urinary precipitates induced by an acidified reagent, in dissolving up completely on adding a drop or two of acetic acid or a citric test-paper;[2] and in diminishing, but not disappearing, on boiling.[3] The opacity is not affected by such warmth as suffices for the solution of urates, or even by a higher temperature than this implies. You observe that when the test solution is run upon urines containing an excess of bile salts, an immediate and very distinctive reaction takes place where the fluids meet—namely, a sharply defined white band of precipitated peptone; and on oscillating the tube, so as to mix up a little of the urine with the test solution, the upper part of the column presents an opacity, the density of which is proportionate to the amount of the bile derivative present, in marked contrast with the transparency of the urine below. On further agitation, a limit is reached when the opalescence diminishes, and perhaps finally vanishes; then it is restored on adding more of the test solution.

Delicacy of the test: objections.—The test is undoubtedly a very delicate one, for I have readily determined by it the presence of one part of bile salts in at least from 18,000 to 20,000 parts of a solution of chloride of sodium. The question will naturally be asked, Is there anything besides bile salts in the urine that will react in like manner with an acidified solution of peptone? So far I have *failed* to put my finger on any such constituent; and I have tried several, among them kreatin, kreatinin, leucin, tyrosin, hippuric acid, and fatty acids (monatomic and diatomic).[4] Besides this failure to discover in the urine a non-biliary substance that can precipitate the peptone, all the positive evidence hitherto obtained undoubtedly supports the position that it is a liver-derived product present in the urine which reacts with the test. The testimony of the facts is cogent in this direction. (*a*) The biliary salts extracted from the bile produce an identical reaction. (*b*) The liver is the sole organ that furnishes a secretion which precipitates a proteid from an acid solution. All the secretions except bile either do not act on the proteids at all, such as saliva, or they dissolve them, such as the gastric and pancreatic juices; and, furthermore, the biliary salts are the only constituents of the bile that possess the property of throwing a proteid out of solution. (*c*) Then I must refer you to the physiological and clinical data which I hope to bring forward in my next communication. These definitely show the connexion that subsists between the proportions of the substance which the peptone test detects in the urine, and the varying degrees of activity of the liver, as well as the diseases and disorders of this organ. I have checked mucin and urates—the fallacies to which all acid urinary tests are liable. The *mucin* of urine of normal reaction is in acid solution. I have elsewhere[5] shown that when this albuminoid body is thus dissolved it is not precipitated by the addition of further acid. So that when this constituent is thrown down in urine of acid reaction, it seems highly probable that the acid added is not the reagent, but merely supplies the requisite degree of acidity to enable the precipitant already present to operate—as in the case of the bile salts and albumen. If so, a mucin precipitate merely indicates the presence of bile salts. Furthermore, on running the test solution on the muciparous mixture of normal urine and clear saliva, the reaction is rather diminished than intensified, and it is *nil* when a solution of chloride of sodium is substituted for the urine. Then, again, the methods of observation requiring a uniform low specific gravity obviate a liability to error from this cause.

Urates.—Inasmuch as the modes of testing—both qualitative and quantitative—require the uniform dilution of the urines to the specific gravity of 1008, a condition is provided which secures the solution rather than the deposition of urates; so that all observations may be trusted without the necessity of resorting to warmth as a corrective. Even when testing the urine undiluted, I have not once observed a precipitation of urates.

The mode of preliminary testing.—In every case the urine to be tested must be quite clear. If turbid from urates, it should be clarified by warmth; if from phosphates, very small pieces of citric test-paper should be added and shaken up with the urine until it becomes transparent, special care being taken not to acidify beyond this limit. It is, upon the whole, best to filter turbid urines; and this proceeding is necessary if the cause of the opacity is organic or doubtful. When the urine is cloudy from blood, it should first be boiled[6] and then filtered, for filtering alone does not clarify it. The specific gravity of the urine is to be reduced to 1008.[7] The object of this direction is to obviate fallacious inferences apt to be drawn from reactions with urines of varying densities: concentrated urines often reacting as if there were present an excess of bile salts; and urines of low specific gravity, though sometimes affording a reaction similar to that of normal samples, actually containing an increased proportion. Twenty minims of urine are added to sixty minims of the solution. If the bile salts are present in excess a distinct milkiness appears, which develops somewhat further in the course of a minute or so; and the depth of the opacity is proportionate to the amount of the bile derivatives. If the urine contains the average proportion found in the majority of healthy urines—or, of course, less than that proportion—the reaction is a mere tinge of milkiness, which is, moreover, not immediate.

---

[1] The following is the formula for the solution:—Pulverised peptone (Savory and Moore), thirty grains; salicylic acid, four grains; acetic acid (B.P.), thirty minims; distilled water, eight ounces. Perfect transparency is obtained after repeated filtration.

[2] When, after dropping in the test-paper, the tube is set aside for a minute or two without shaking, the observer will find the portion below quite transparent, and that above still opaque; and on shaking up the contents he will disperse the opalescence throughout.

[3] When the test solution is precipitated by bile salts, the precipitate has the same peculiarities; dissolving when further acidified, and lessening—certainly not vanishing—when boiled.

[4] It is well known that a concentrated solution of chloride of sodium in the presence of an acid will precipitate a proteid. When the chlorides of the urine appear in excess, will they react with the test solution? Experiment shows that when the peptone solution is run upon a solution of salt of any specific gravity less than 1030 no precipitation whatever appears. Therefore the urinary chlorides are not a source of error, and more especially when it is called to mind that a condition of the testing is the reduction of all urines to the uniform specific gravity of 1008.

[5] Bedside Urine-testing. 3rd edition, pp. 110-11.

[6] Boiling the urine does not destroy the bile salts. It is true, if any taurocholate of sodium is present it is broken up, the products being taurin and cholate of sodium; but the peptone test reacts with the cholate as well as with the liver-secreted salt.

[7] This is done very readily by taking the specific gravity of the urine according to the method I follow (see Bedside Urine-testing), a bead of the specific gravity of 1008 being dropped into a measured portion of the urine contained in the tube graduated from 1008 to 1014, and water being added until the bead ceases to rise and remains stationary at any part of the column of fluid.

The contact method.—When the test solution is gently run over a urine (reduced to the specific gravity of 1008) containing bile salts in pathological amount, an immediate reaction takes place; but when the quantity is normal or subnormal, the reaction is not instantaneous—it gradually appears in the course of a minute as a delicate thread-like line, which may undergo a little further development during the lapse of a few minutes.

Quantitative estimation.—Clinical observation demands something more definitely comparable than can be derived from the mere qualitative testing; for it should decide as accurately as possible the quantitative variations of the urinary elimination of the bile salts observable in different pathological conditions, in the various stages of disease, and in the effects of treatment. I have therefore devised the following procedure to meet this requirement. A permanent standard of opacity is needed to represent the small average discharge of bile salts in healthy urine. For this purpose I have selected alumina precipitated by ammonia, because the permanency of this form of opacity has been proved by the alumina standard, which over twelve months ago I devised for quantitative albumen. The opacity of the fluid contained in this small tube is that provided by mixing together in equal proportion (sixty minims) the urine, reduced to the specific gravity of 1008, and the test solution. To sixty minims of the test solution the urine, of the specific gravity of 1008, is added, in ordinary cases ten or twenty minims at a time, and allowing a minute to elapse after each addition, until the opacity induced is seen to be exactly equal to or to slightly overstep that of the standard, the tubes being held to the light, *shaded by a dark background*, such as that of the coat-sleeve. If fifty or sixty minims of the urine bring up the opacity merely to that of the standard, the proportion of bile salts is not outside the normal range in the direction of increase. But any smaller quantity of urine required indicates an excess of the biliary derivatives over the physiological variations. The smaller the amount of urine needed, the larger the proportion of bile salts present, according to the following table:—

Urine.				Percentage increase of bile-salts over the normal maximum.
Minims.		Drops.		
1	or	2	=	3000
2	"	4	=	1500
3	"	6	=	1000
4	"	8	=	750
5	"	10	=	600
10	"	20	=	300
15	"	30	=	200
20	"	40	=	150
25	"	50	=	120
30	"	60	=	100
35	"	70	=	83
40	"	80	=	66
45	"	90	=	50

Charges of bile-salts beyond 700 per cent. increase over the normal maximum amount are only met with now and then; but they may be encountered in isolated samples of even non-jaundiced urine; as in a specimen I show you which I lately met with containing 1500 per cent. increase of biliary salts, but quite free from bile pigment.[8]

The peptone test-paper.[9]—I have arranged the peptone test in the form of test-paper, so as to serve the convenience of observers in the preliminary testing. The test-paper is permanent and reliable, and is best used in the following manner: The peptone test-paper along with half a citric paper is dropped into fifty or sixty minims of water in the larger test-tube or a wine-glass; after the lapse of a minute or so the solution is slightly agitated, and on being set aside for another minute[10] is ready for use. The solution thus prepared is taken up by the pipette and carefully run over the transparent urine, when, if bile salts are present in larger amount than the normal average, an immediate reaction is observed, as a pearly-white thread or band; but, with urine devoid of this excess, a delicate zone may appear, but only in the course of from one to two minutes. The test may likewise be employed equally well in the following ready way: The test-paper along with half a citric paper is dropped into sixty minims of water, and twenty minims of urine reduced to the specific gravity of 1008 are added. The contents of the tube are oscillated for half a minute, and then set aside for a minute, so as to allow time for the clearing away of gaseous particles and the development of the reaction. If bile salts are present in excess a distinct milkiness is apparent, but if in normal or subnormal amount there is only a slight haze, or no obvious change.

CHRONIC CHOREA OF FORTY-ONE YEARS' DURATION; NERVE-STRETCHING FOR RELIEF OF PAIN.

BY AYMER R. MACDOUGALL, M.B. EDIN., M.R.C.S.

THE LANCET of November 29th and of February 21st publishes papers by Dr. Saundby of Birmingham and Dr. J. C. McLearn, treating of the subject of Chorea in the Aged. While the matter is still fresh in the minds of your readers the following notes of a case of chronic chorea in a person of somewhat advanced years on whom nerve-stretching was performed will, I trust, prove interesting. At the outset I may state that the nerve-stretching was not performed with the primary object of curing the chorea, but was necessitated on account of severe and intractable pain, limited to the regions supplied by the anterior crural nerve. I hoped, however, not only that the pain would be removed, but that a favourable influence, even though slight, might be exerted on the chorea. As the sequel shows, in this I was not disappointed, for, though the chorea still continued, the movements were much less severe than they had been, while the pain itself was completely removed, and remained absent for rather more than two years.

The patient, Mary A——, aged fifty, an inmate of the Border Counties Home for Incurables, had suffered from choreic movements for the last forty-one years. Her family history was good; no evidence of nervous disease in any of the other relatives could be obtained. Up to the age of nine the patient was strong and healthy. At that time she received an injury to the lumbar portion of her spine, followed by partial loss of power in the lower extremities. Shortly afterwards spasmodic involuntary movements commenced in the muscles of the left calf. These, at first slight and localised, gradually became more diffused and severe. The left thigh became affected, then the right lower limb, and subsequently the trunk, arms, and head. This extension occurred very slowly, many years elapsing before the movements became general. During the last two years, even when assisted, she has been quite unable to walk. Prior to this when walking she frequently suffered from retropulsion.

At the time of operation the condition of the patient—a pale, feeble, emaciated woman—was as follows:—Her extremities, head, and trunk were in constant motion, save when she was asleep. Then the movements ceased entirely. The muscles of the face were affected. The arms were less involved than the other parts of the body. She could seize a large object and hold it for a second or two. The tongue could be protruded straight and held out steadily; but so severe were the general movements that the patient was quite unable to rest in bed or to sit on a chair. The only posture in which she could find partial relief was by kneeling on the floor and resting the upper portion of the body on some support. Her sleep was thus much interfered with, and, to add to her misery, a constant shooting pain in the inner and anterior aspects of the right thigh had tormented her for the last three or four months. The muscular power was diminished; her grasp was feeble, but that with the right hand was stronger than with the left. Power in the lower limbs was also markedly impaired. Sensation was everywhere normal save at the inner and anterior aspects of the right thigh, where it was increased. Knee reflex was present on both sides; no ankle clonus. The spine on inspection appeared normal; but, when percussed, pain was complained of over the seventh and eighth dorsal and also over the lumbar vertebræ; when a hot sponge was passed along the spine she felt it much more keenly at those spots. The action of the bladder and rectum was normal, as were also the special senses. The patient was irritable and childish in manner.

---

[8] Pettenkofer's test afforded at once a beautiful reaction with this sample.

[9] These test-papers, the apparatus for taking the specific gravity, the standard opacity, suitable test-tubes, pipette, &c., as well as the peptone solution, are supplied by Messrs. Wilson and Son, Harrogate.

[10] The solution thus left at rest for a short time becomes quite transparent.

As many local and general remedies had been tried without effect, and as her general health was suffering sadly from the constant pain and want of rest, I offered her the chance of such relief as nerve-stretching, from what I had read of it, seemed to give. This chance she eagerly grasped at, and on March 31st, 1881, assisted by Mr. Page and Dr. Barnes, I stretched the right anterior crural nerve. The incision, an inch and a half long, was made half an inch to the outer side of the femoral vessels. The nerve was easily found, and, having been cleared from the surrounding parts, a blunt hook was gently passed under it. On this the nerve was raised sufficiently to allow of its being grasped between the thumb and forefinger, when it was twice pulled strongly from above downwards and from below upwards. The nerve was then replaced, the wound washed with carbolic lotion, the edges brought together with silver sutures, and a small horsehair drain inserted. When the patient recovered from the anæsthetic, she was absolutely free from pain and from the choreic movements; the latter did not return until the evening, some seven or eight hours after the operation. On subsequent examination, sensation in the parts supplied by the anterior crural nerve was discovered to be almost *nil*, especially as regarded pain. There was no power of flexing the thigh or raising the limb from the bed. April 1st: The patient had had a good night. Wound dressed, looking well; no pain. The choreic movements are exceedingly slight, those of the right leg not so marked as the left. Had "jumping" in the right limb during the night. Sensation on the right side much the same as yesterday. The right thigh felt somewhat warmer than the left.—2nd: Choreic movements not increased. Sensation and motor power somewhat better. Can feel the prick of a pin when inserted deeply.—4th: Sensation returning much more rapidly than motion. She can feel the touch of a finger placed on the anterior part of the thigh; perception, however, seems somewhat delayed when compared with the left. Pain is distinctly and rapidly felt. She can flex the thigh a very little to-day, but cannot raise the limb from the bed. The right thigh to the touch still feels warmer than the left. Sutures and drain removed. Wound healed, save in the line of the drain.—6th: Sensation seems equal on both sides. No apparent delay in the transmission of impressions. She can now flex the thigh more strongly and rapidly, and can raise it a few inches from the bed. Her general condition has much improved since the operation. She is more cheerful, and eats and sleeps well.—By April 25th the patient was able not only with slight assistance to walk about the ward, but she could sit easily in a chair, which she had not been able to do for many months. There had been absolutely no pain, and the motor power had increased; the right limb, however, was not so strong as the left.

When the patient was examined in February, 1883, nearly two years after the nerve-stretching, the chorea was found to be rather more severe than at the last report, though not nearly so much so as before the operation. She was still able to lie in bed or to sit upon a chair. Power in the right limb was found diminished, both in flexing the thigh and in pushing against obstacles. Her walking was also worse, and more support was required to be given. She had had no return of the pain. Fourteen months later she stated that the old pain had returned, and, though not nearly so severe as prior to the operation, her sleep was a good deal disturbed by it. The choreic movements appeared to be in much the same state as in February, 1883. Sensation was apparently equal in both thighs, and there was no delay in the transmission of impressions. When the spine was percussed the first and second lumbar vertebræ were found to be more tender than the others, and here also the hot sponge was more clearly felt. When measured two inches below the great trochanter, the right thigh was found to be 13½ in.; the left, at the same level, 14½ in. As the limbs were not measured before the operation, no importance can be attached to this difference in the circumference. The muscles of the right thigh seemed not only smaller, but felt softer than those of the left.

So far as I know, no case of chorea has been recorded in which nerve-stretching has been tried. Nor would one, considering the pathology of the disease, expect much good to follow such a procedure. Few, however, will doubt that in this case the operation, undertaken for another condition, was followed by marked improvement in the chorea. Three years had elapsed when I last saw the patient, and even then the benefit had not entirely passed away. Signs, however, were not wanting to show that the disease, though slowly, was steadily resuming its old characters.

Chesterfield.

IS ALCOHOL A FOOD?

BY T. W. THOMPSON, M.R.C.S.,

LATE SURGEON 1ST LIFE GUARDS.

IT is perhaps a little surprising that in this age of scientific energy a subject of such intrinsic importance and universal interest as the one I now propose to reopen should remain in the region of uncertainty. The importance of the subject becomes evident when we remember that the position occupied by alcohol in the civilised world, both as a staple article of diet and as a therapeutic agent, rests to a great extent on its supposed nutritive properties. The uncertainty with which the matter is still surrounded is sufficiently evidenced by the opposite opinions that continue to prevail, not alone among the general public, but even in the ranks of the scientific. These differences of opinion are often attributed to individual prejudice; I cannot but think, however, that, among the scientific at least, prejudice would ere this have succumbed to demonstration had this been forthcoming.

Without for a moment under-estimating the importance of the experimental researches of Anstie, Parkes, Dupré, Thudichum, and others, my contention is that, though the facts accumulated by those distinguished observers furnish a strong presumption in favour of the view that alcohol is a food, they nevertheless fall short of the requirements of proof. So much was admitted by Parkes himself, who said "the experimental evidence is incomplete (chiefly on account of the difficulty of collecting the amount given off by the lungs and skin)." In this sentence Parkes certainly points out the proximate cause of the failure of previous investigators to reduce the matter to demonstration, but as the difficulty of collecting all the alcohol given off by the lungs and skin (and we may add, bowels) amounts practically to an impossibility, I venture to suggest that the ultimate cause of their failure was that the logical arrangement of their experiments was unsuited to the peculiar conditions of the inquiry.

To explain my meaning more fully I must call attention to the plan upon which they proceeded, which was as follows:—Having administered a measured dose of alcohol to a subject, they endeavoured to collect the absolute amount eliminated by all the possible channels, with the view of comparing the amount administered with that eliminated, the difference between the two being assumed to represent the quantity that had been split up in the system and utilised as food. Now, if this method were practicable it could hardly fail to be conclusive; but, as already said, the difficulty of estimating the amount eliminated by the lungs, skin, and bowels with any degree of accuracy is, and probably always will be, insurmountable. This method, then, is never likely to furnish more than presumptive evidence, which must ever remain a prey to the criticisms of the sceptic. If we would reduce the matter to anything like demonstration, it would seem evident that we must resort to a different method.

I now propose an alternative line of investigation, which, in my opinion, is capable, if properly worked out, of yielding a positive result. The problem being to ascertain whether alcohol is or is not a food, we should endeavour to ascertain whether it is to any extent capable of taking the place of other foods. We cannot, unfortunately, proceed upon the simple plan of trying whether it is possible to sustain life for an indefinite period on a diet of alcohol alone, for since alcohol contains no nitrogen we know such a result to be impossible; it may, however, be a food nevertheless. The simplest and most conclusive method would seem to be the following:—

Ascertain, by a series of experiments arranged strictly in accordance with the Method of Difference, whether, of measured doses of alcohol administered, the amount eliminated is or is not influenced by the amount of other food taken. For instance, supposing alcohol to be a food, then, other things being equal, we should anticipate that the amount eliminated when the demand of the body for nourishment had already been amply supplied from other sources would be greater than when the reverse was the case, as in starvation. This difference would be observable equally by all the channels of elimination; it would, therefore, be sufficiently conclusive of the connexion of cause and effect if the elimination by any one channel was carefully studied under these different conditions. The difficult and uncertain channels might thus be neglected, and the more workable one (the urinary) adopted for observation.

To bring out still more prominently the connexion of cause and effect, this line of investigation might be pushed further by proceeding to the nicer distinctions exhibited by the Method of Concomitant Variations. If we could show that, other things being equal, of measured doses of alcohol administered, the amount eliminated by the kidneys always varied *proportionately* with the amount of other food taken, the fact of alcohol being capable of taking the place of some of the other nutritive elements would be established by all the weight of evidence that the inductive methods are capable of affording.

Acting upon the views above expressed, I have, in conjunction with Dr. G. A. Hamerton, worked out a few experiments, which I record below, and which, as far as they go, point unequivocally to the conclusion that alcohol is a food. I say as far as they go, because, inasmuch as they are of limited extent, and were performed under considerable practical difficulties, I should not wish to attach too much importance to them in the absence of corroboration. When I first entertained the idea of working out this subject I hoped to be able to carry it through, but I soon found that the time and facilities for experimentation afforded by a straggling country practice were altogether inadequate to the requirements of the inquiry. I have therefore been obliged to abandon the notion of working it out more thoroughly myself, and I have come to the conclusion that under the circumstances the best course is to put my view of the matter (with such experiments as we have already made) before the profession, feeling sure that if that view is a sound one it will certainly be worked out by others who are fortunate enough to be possessed of the required opportunities. I must, however, point out that, while admitting the possibility of our results being modified by more extended observations, I have no want of faith whatever in the method I have suggested, but hold confidently the opinion that, if carefully worked out, it must settle the question of the food value of alcohol one way or the other.

Coming next to our experiments, I may say first that, with the view of avoiding unnecessary sources of error, they were worked out only upon ourselves and one friend, in whom we have the greatest confidence. The test employed was the chromic acid colour test used for a similar purpose by Anstie, Thudichum, and Dupré, and all the precautions suggested by those distinguished observers were carefully adopted. For the information of those who may not be conversant with the *rationale* of this test, I should perhaps explain that it depends on the power of alcohol to reduce free chromic acid, when well diluted with sulphuric acid, into sulphate or oxide of chromium, which reaction is evidenced by a change of colour from red to green, the intensity of the change corresponding to the amount of alcohol present in the suspected fluid. Our general plan was as follows:—

Two experiments were to be made on the same individual. In Experiment 1 a demand for nourishment was to be created by exercise and starvation; in Experiment 2 the demand for nourishment was to be reduced to a minimum by rest and feeding. All the other circumstances were to be, as far as possible, identical in the two observations. On each occasion the same quantity of alcohol was to be taken, in the same doses and at the same hours. The relative amount of alcohol eliminated by the kidneys in the two cases was then to be compared. In anticipation of the possible criticism that in the first observation the skin elimination would be favoured by the exercise, I must point out that the first dose of alcohol was not taken till an hour after the exercise was completed, and that every precaution was taken to reduce the skin elimination to a minimum. Still, should this objection be seriously pressed, it would be easy, and perhaps more strictly in accordance with the Method of Difference, in any repetition of these experiments to vary the circumstance of food alone.

Experiment 1.—A. having abstained from alcohol for one week, the urine was examined on the evening of July 7th, 1884, and proved to be free from alcohol. The only food taken from 7 P.M. on the 7th till 9 A.M. on the 9th—an interval of thirty-eight hours—was, on July 8th, for breakfast, one egg, one small piece of toast (less than an ounce), and one cup of tea without sugar and milk; for lunch (1.30 P.M.), two ounces of beefsteak and one ounce of toast. On this day A. did an ordinary day's work, and, in addition, played two sets of tennis. At 7 P.M. he had a cold bath, put on cool comfortable clothes, and sat out of doors for the remainder of the evening. At 7.15 P.M. he passed urine, and at 7.30, feeling considerably exhausted, took the first dose of alcohol, which consisted of one-fourth part of a mixture consisting of an ounce and a half of Scotch whisky and two ounces and a half of water. The remaining three doses were taken at intervals of an hour. At eleven o'clock he retired to bed. All the urine passed between 7.15 P.M. on the 8th and 9 A.M. on the morning of the 9th was collected. Of this, 50 c.c. were put into a retort, with a little tannic acid to prevent frothing, and distilled to one-half through an air-tight Liebig's condenser into a receiver fitted with a mercurial valve. The distillate, to which was added a little caustic potash, was then redistilled. This second distillate was next distilled to one half with a little sulphuric acid. By these means the fluid was concentrated to one-eighth, and all the volatile alkalies and acids were removed. The final distillate was then put into a large test-tube which was connected by glass tubing on the one side to a continuously acting bellows, and on the other to a U-shaped tube containing a mixture of one part of dichromate of potash to three hundred parts of sulphuric acid. The U-shaped tube was again connected with a second test-tube containing the same acid mixture. Air was now pumped through the apparatus in a continuous stream for half an hour, and no change of colour occurred in the test solution either at the time or after standing.

Experiment 2.—After an interval of a fortnight, during which time A. had of course abstained from alcohol, the experiment already described was repeated on him, the only difference in the conditions being that on this occasion he ate as much and as often as he could, and exerted himself as little as possible. The whisky (out of the same bottle as before) was taken in the same doses and at the same hours, and the remaining details of the experiment were identical with those of the previous one. This time, when air was pumped through the urine distillate, a slight change of colour was soon observed in the test solution, which at the expiration of half an hour was of an evident greenish hue, which deepened after standing.

These two experiments were then repeated on B. and C., special care being taken to ensure that the conditions were identical with those of the previous experiments. In both of these cases the results obtained were exactly the same as those just described in connexion with A. While the subjects were creating a demand for nourishment by exercise and starvation there was no ascertainable elimination of alcohol by the kidneys. When, on the other hand, the demand for nourishment was reduced to a minimum by rest and feeding the elimination of alcohol by the kidneys was easily demonstrated, even after so small a dose as an ounce and a half of whisky, or probably about six drachms of absolute alcohol.

It will be seen that we only carried our experiments to the Method of Difference, and did not extend them in accordance with the Method of Concomitant Variations. The obvious reason was that, apart from want of time &c., a colour test is not sufficiently accurate for the nicer distinctions of the latter method, while the quantitative tests for alcohol are extremely difficult, and could hardly be worked out of a regular laboratory. Admitting that the case would be very much strengthened if corroborated by the Method of Concomitant Variations, I must at the same time express my belief that unless our results have been rendered fallacious by errors of practical manipulation, which I can hardly think probable, our experiments certainly indicate in the clearest manner that alcohol in small doses, at all events, is a source of nourishment—i.e., a food.

In conclusion, I must express my indebtedness to Dr. Hamerton for his valuable help in the practical working out of the experiments, without which, indeed, it would have been impossible for me, situated as I was, to have undertaken the inquiry at all.

Potter's Bar.

CASE OF

CARIES OF THE SPINE, WITH PARTIAL PARAPLEGIA, TREATED BY THE APPLICATION OF SAYRE'S JACKET;

RECOVERY OF POWER OF LOCOMOTION IN TWENTY-FOUR HOURS.

BY MARTIN OXLEY, M.D.,
CONSULTING PHYSICIAN TO THE LIVERPOOL INFIRMARY FOR CHILDREN.

MARY D——, aged ten years, came under notice on June 1st, 1883. There was disease of the fourth, fifth, and sixth dorsal, also last dorsal and first lumbar vertebræ, there being two distinct angular curves, the upper the more marked. She had been four months in the Aberystwith Infirmary under treatment. When discharged she had lost the use of her legs, and could not stand or walk. When seen by me she was unable to walk, although she could stand with assistance. She cried out suddenly with pain, caused by spasmodic jerking of her right leg. I applied a Sayre's jacket and a jury-mast while she was suspended, putting on extension enough to straighten the body, but without attempting to open out the two angular curves. The feet were flat on the ground, and she grasped the cross bar with her hands, an assistant giving her support and steadying her during the application of the jacket. She was then placed in bed. The next day, on my visiting her, I was told that she had been out of bed,[1] and had walked without difficulty. On hearing this I tested her walking powers, and found that they were quite restored. She went to her friends in Liverpool until November 10th, 1883, when she returned to have a new jacket. She was then in excellent health, and I exhibited her at a meeting of the Medical Institute. In June, 1884, she had a new jacket applied, and was able to walk about without any support. Now (April, 1885) the patient is again in Liverpool,[2] and has had a new jacket and jury-mast applied. She is able to go about quite comfortably without the support; but having seen bad results follow when the corset has been given up too soon, I intend to keep a light jacket on for some years.

Remarks.—The relation of this case will, I hope, convince those who doubt the efficacy of Sayre's mode of treating spinal caries—viz., by the application of a well-fitting plaster corset, which allows the patient at once to walk about and behave like a healthy individual. I consider the above as good an instance for testing Sayre's method as one could have. 1. The patient is old enough to speak for herself, and is highly intelligent. 2. She had previously been under treatment in hospital, under a skilful surgeon, by rest in the recumbent position. 3. She had disease of two separate portions of her spine—viz., the fourth, fifth, and sixth dorsal and the twelfth dorsal and first lumbar vertebræ. 4. She was unable to walk when she came under treatment. Further, a few days after the application of the jacket she was sent out into what we know too well as squalid Liverpool; and when she came to see me again, six months after the first application of the jacket, her dirty condition told very plainly how little care had been bestowed upon her.

Liverpool.

A NEW REMEDY IN GOUTY OBESITY AND DYSPEPSIA.

BY J. MORTIMER GRANVILLE, M.D.

I HAVE been obtaining some very good results of late in cases of gouty obesity and dyspepsia with a remedy which, although familiar and based on the simplest physiological principles, is, so far as I am aware, new as I use it. It occurred to me some time ago, as indicated by the physiological state in gout, chronic and irregular; and having now had ample opportunities of trying it, I venture to suggest it to practitioners generally, to whom I think it will at once commend itself as essentially *likely* to be of service.

One of the earliest, if not a primary, error of function in gout, whatever may be the real *cause* of that malady, is failure of the liver to secrete sufficient, or normally constituted, bile. The product of liver function is, as we know, excremento-recrementitial, the greater part of the bile being re-absorbed in the intestines; and among other uses in the economy, such as helping to hold the cholesterin, *and perhaps the uric acid*, in solution, it is destined to facilitate the proper digestion and assimilation of fats. If fat be not duly assimilated, it will be deposited crudely, as in the omentum and elsewhere, with the result of obesity, coupled with deficiency of heat production and maintenance; which is a very different thing from obesity with full or even excessive powers of calorification. I think it is important to make this discrimination between two distinct and totally different classes of cases. In the former class—common in persons with an inheritance of gout, in which there is obesity with a low grade of heat-force,—I am giving the biliary salts, extracted from ox bile, in the form of a pill, to be taken as pepsine is taken, with food. The results are very striking. The stools are rendered characteristically rich in bile without purging, the food is readily digested, and the accumulations of fat seem to melt slowly away. The taurocholate of soda with the glycocholate of soda are readily obtained from ox bile by evaporating to dryness and pulverising, making an alcoholic extract, filtering, and precipitating by small successive additions of ether. The deposit is non-crystallisable so far as the taurocholate of soda is concerned, while the glycocholate of soda appears, if the deposit be left to stand, in acicular crystals, forming themselves into rosettes. With any suitable excipient the mass may be readily made into pills, each containing about four grains of the taurocholate, and coated *so as not to dissolve in the stomach*. One should be given with each meal or immediately after food. The effect of this new remedy, both for defective digestion and assimilation, and for obesity in cases in which fat is accumulated instead of being burnt off in the system as nutritive fuel, will, I think, be found highly satisfactory.

Hanover-square, W.

AN INSTRUMENT FOR THE TRANSFUSION OF DEFIBRINATED BLOOD.[1]

BY T. W. CARMALT JONES.

THIS instrument is intended to be used for transfusing defibrinated blood. It could be equally well used for injecting milk or any other fluid into a vein. It consists of a holder (A), into which the defibrinated blood is to be poured; a tight-fitting metal cap (L), in the centre of which is a hole, a pipe leading from this hole communicates by means of an indiarubber tube with a valved handball (T). When the cap is in position on A, air can pass easily to A, but pressure on the handball will force air into A and compress it on the surface of the fluid in A. At the lower end of A is a piece of indiarubber tubing (B), which can be compressed by the clip D, and at the other end of the tubing is a hollow coned metal plug (C), which fits into the silver nozzle (M). The instrument with its accessories, as supplied in the case, provides all that is required for the performance of the operation of transfusion of defibrinated blood, with the exception of a clean ordinary tumbler, or, preferably, a small milk-jug and a basin of hot water. The steps of the operation are as follows. 1. Bleed the donor, in an adjoining room if possible, to five or six ounces into the measured vessel (H). 2. Whip the blood with the whip (P), and strain through the strainer into the tumbler or milk-jug. 3. See that the indiarubber tube (B), plug (C), and clip (D) are in place. Pour the defibrinated fluid into the holder (A), and put the cap (L) on firmly, then place the holder in the basin of water at 100° F. 4. Open a vein in the patient's arm, and insert the silver nozzle (M, K, or I)—three sizes of nozzles are provided—and block up the open end of the nozzle with the finger. 5. Have the holder brought to you; ease the clip until the fluid flows out of the plug, then tighten the clip again, take the finger away from the end of the nozzle, and insert the plug and remove the clip. Note the height of the fluid in A. The fluid in the holder is now in free and direct communication with the blood in the patient's vein. If any force is required, squeeze the handball gently. 6. After the operation is over again note the height of the fluid in A, remove the short piece of indiarubber tubing (B) and burn it. The other parts can then be easily and thoroughly cleaned.

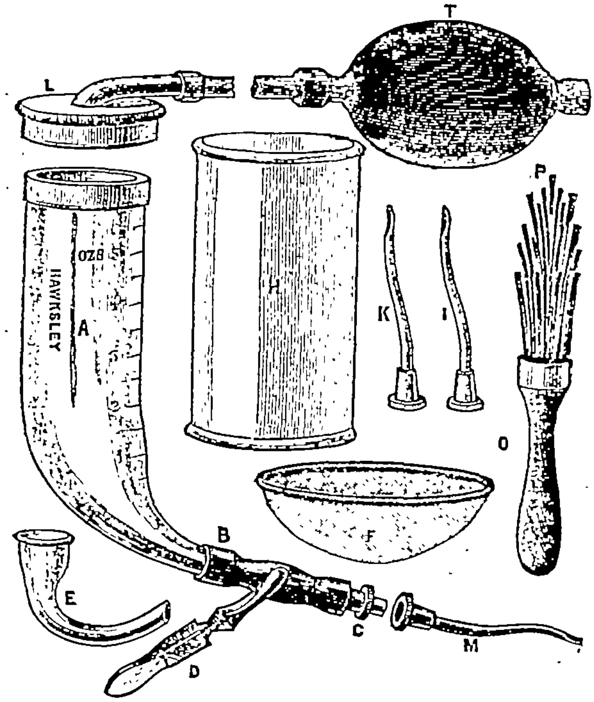
---

[1] This was contrary to my orders, as I always keep my Sayre's cases in bed between the blankets for three days after the application.

[2] I again showed her to the members of the Medical Institute at one of their meetings, this time without the jacket.

[1] A paper read before the Harveian Society of London, March 5th, 1885.

The instrument is very simple in action, has no delicate or complicated parts that can get out of order so as to cripple it, has no taps to puzzle the operator, and can be thoroughly cleaned and inspected. Supposing anything were to happen to the handball, an assistant could supply all the force required by blowing, though not so conveniently as by the handball. The piece of indiarubber tubing at B is to be a clean new piece each time the instrument is used, and is to be burnt directly after use, so that no danger may arise from dried blood not removed after previous use. The inside of indiarubber tubing is rough and not easily cleaned, and cannot be inspected to see if it is clean. This piece of tubing allows sufficient play and breaks the rigidity, but is purposely kept short. The amount of blood taken from the donor and the exact amount injected into the patient will be known. The instrument is made for me by Mr. Hawksley of Oxford-street, to whom I am indebted for several practical suggestions.



H, Vessel marked in ounces for donor to be bled into. P, Whip to be used in H. F, Strainer of lawn muslin on wire frame. A, Holder to receive defibrinated fluid. B, Indiarubber tube about three inches long. C, Coned plug (hollow). D, Clip. L, Metal cap for A. T, Handball. M, Nozzle. K, I, Additional nozzles. E, Blood director.

ANTHROPOLOGICAL INSTITUTE.—At a meeting held on April 14th (Professor Flower, F.R.S., Vice-President in the chair), Dr. J. G. Garson read a paper on the "Inhabitants of Tierra del Fuego." Three tribes inhabit the Archipelago of Tierra del Fuego: they are called the Onas, who occupy the north and east shores, and resemble the Patagonians in being a tall race, chiefly living by hunting, but supplementing their food with shellfish and other marine animals; the Yahgans, who live on the shores of the Beagle Channel and Southern Islands—a short, stunted race, subsisting almost entirely on the products of the sea and birds; the Alaculoofs, who dwell in the Western Islands, and are closely similar to the Yahgans. These last two tribes lead a very degraded life, wandering from place to place; they possess no houses, but construct shelters out of the branches of trees; they build canoes of bark, and wear very little clothing. In stature they are short, the men averaging about 5 ft. 3 in., and the women about 5 ft. In cranial and osseous development they resemble the other wild native tribes of America, but by isolation have assumed certain characters peculiar to themselves. The population of the Fuegoan Islands appears to be about 3000.

OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

MIDDLESEX HOSPITAL.

THE following two cases of hernia are of considerable interest. In the first, where hæmorrhage from a deeply-seated vessel complicated the operation for strangulated femoral hernia, we have an example of a condition which is very uncommon, and which, when it does occur, is usually due to an abnormal position of the obturator artery, the hæmorrhage arising from a wound of which is apt to be very troublesome. The second case is one in which the removal of the sac was carried out as an essential part of the treatment, and Mr. Hulke pointed out to his class the importance of closing the peritoneal cavity, and so preventing drainage backwards of discharges from the wound into the abdomen, a frequent cause of fatal peritonitis.

For the reports of the cases we are indebted to Mr. Ernest E. King, house-surgeon.

STRANGULATED FEMORAL HERNIA; OPERATION; RECOVERY.

(Under the care of Mr. J. W. HULKE.)

M. R—, aged forty-five, a washerwoman, was admitted on Jan. 29th, 1885, complaining of swelling in the upper part of the right thigh, accompanied with pain in the abdomen and retching. The patient states she has had a swelling in the right thigh since her last confinement, eight years ago, but it has never given her any inconvenience, and she has never worn a truss. Five days ago she got a "chill" and began retching, and, the retching continuing, she noticed the swelling in her thigh was larger than usual, and somewhat tender. Thirty hours before admission the symptoms became aggravated; bowels not open for three days. She describes the vomited matter as "clear, watery, and frothy."

The patient's state on admission was as follows. In the upper part of the right thigh, external to and below the spine of the pubes, was a swelling about four inches long by two and a half wide, its long axis being from below upwards and outwards. On palpation the swelling was fluctuating, and a thrill of fluid could be distinctly felt. The lower border was much better defined than the other. It extended beyond Poupart's ligament, and was superficial to it. No impulse on coughing; dull on percussion, except on a very small area close to the spine of the pubis. It was irreducible. She had also an umbilical hernia. The disease was diagnosed to be strangulated femoral hernia, probably both gut and omentum.

☞Two hours after admission the patient was placed under ether, and an incision was made over the inner border of the swelling until the sac was reached. On opening the sac a large quantity of bloody serous fluid escaped (roughly estimated at two ounces). The finger was then passed in, and the gut was found to be surrounded by adherent omentum in places; consequently the wound was enlarged upwards and downwards; one or two vessels were divided, but easily controlled. The finger was then passed to Gimbernat's ligament, which was divided. As the hernia was still irreducible, the omentum was isolated as far as possible, and the pedicle transfixed with an aneurysm needle and double ligature, and the omentum carefully snipped away with scissors. There was no further hæmorrhage at this stage. The gut was then returned, and two or three little oozing points ligatured. After they had been stopped it was noticed that there was still bleeding from the bottom of the wound, and a ligature was passed with an aneurysm needle beneath it and tied, and the hæmorrhage being apparently checked, the closing of the wound was proceeded with; but again blood welled up, and the wound was freely opened and large retractors introduced, and at once a comparatively large atheromatous artery was seen spouting away freely. From its position it was evident that this was a large communicating artery between the deep epigastric and the obturator, lying just behind Gimbernat's ligament; it gave very great difficulty in securing, which was only accomplished by making a still freer incision and picking up both ends and tying. The wound was then washed with a strong solution of chloride of zinc, dusted with iodoform, a long drainage-tube inserted, closed with sutures, and dressed with antiseptic gauze. The portion of omentum removed, when spread out, was as large as the palm of the hand.

Jan. 30th.—The patient passed a fairly good night, although troubled by cough at times, which was treated with an occasional dose of linctus morphiæ. She had some little pain in the wound, and took three half-grain opium pills during the night and a little milk and lime-water.—9 A.M.: Pulse 104; temperature 101·4°. Some slight abdominal tenderness.—2 P.M.: Wound dressed; looking well; a little blood-coloured inodorous discharge.

31st.—9 A.M.: Pulse 96; temperature 100·2°; the temperature during the night had reached 102·2°; has a little bronchial catarrh. Ordered an ounce of compound draught of senega every four hours. Wound again dressed; looking well, but had some slight tenderness over abdomen.

Feb. 2nd.—9 A.M.: Pulse 100; temperature 100·8°.

3rd.—Pulse 100; temperature 100°. From this date the patient improved, the wound granulating well. The drainage-tubes were removed, and on March 17th she was walking about the ward wearing a truss and in good health.

STRANGULATED UMBILICAL HERNIA; OPERATION; REMOVAL OF THE SAC AFTER LIGATURE OF THE NECK; RECOVERY.

(*Under the care of* Mr. J. W. HULKE.)

E. O——, a man aged sixty-one years, was admitted at 9 P.M. on March 3rd, 1885, complaining of some vomiting and constipation, and a large swelling about the umbilicus. He stated that for five years he had suffered from hernia, but that he could always reduce it easily; for the last two years he had worn a belt, and there had always been more or less swelling. On March 1st, without any apparent cause, he experienced pain in the abdomen, and noticed that the swelling was larger; he vomited after taking any food. On the 2nd he placed himself under medical treatment. Ice was tried, and an attempt at reduction made, but this failed, and, the vomiting and constipation continuing, he was advised to come to the hospital; but twelve hours previous to admission he took a large dose of castor oil and fomented the rupture on his own responsibility. This failing to act, he sought admission.

On admission there was a large swelling about the size of the clenched fist in the umbilical region. Its upper surface was almost entirely denuded of epithelium from the application of poultices, ice, &c. On palpation the swelling was found to extend some distance beneath the skin, more than was apparent to the eye. It was very hard, gave no impulse on coughing, was irreducible, but only very slightly tender on manipulation. It was diagnosed to be strangulated umbilical hernia.

Mr. Hulke, being in the hospital, decided to place the patient under ether at once, and if taxis failed—which it did—to operate at once. The parts were first washed out with carbolic solution, and iodoform dusted into the umbilicus. A semicircular incision was made at the upper and left outer margin of the swelling, with the intention of dissecting down to the constriction, and reducing, if possible, without opening the sac; but after carrying the dissection down a considerable distance, it was found impossible to do this, and another incision was made, running outwards and upwards from the centre of the umbilicus, and cutting the previous one at right angles. The strictures were then very carefully divided until a deep red and congested tissue, which looked and felt exactly like the bowel, came into view, but the finger could not be passed round the swelling; and the incision was further increased by two diverging ones, and then beneath this thickened membrane a bubble of air and fluid could be seen, showing evidently that this was the sac, and it was consequently picked up and pricked, and a large quantity of blood-coloured watery fluid escaped, showing the sac had been opened. It was freely divided, and a large piece of omentum deeply congested came into view; this was pulled forward, and numerous double ligatures passed through and firmly tied; the mass was then cut away (it weighed twelve ounces). The finger was next passed down to the constriction, which was found to be very tight and fibrous, and was divided with a hernia knife; a few bleeding points were ligatured. The whole surface was then thoroughly washed with carbolic solution (1 in 20), and there being no bleeding whatever, the stump was pocketed. The sac was next dealt with, and was found to be adherent nearly throughout its entire outer surface to the abdominal wall; it was freed by stripping it away, pulled well forwards, and the finger introduced to its own base inside; a ligature was tied round at this point as the finger was withdrawn, and the upper portion entirely cut away. Drainage-tubes were inserted, the edges of the wound brought together with waxed silk sutures, iodoform dusted over, and gauze dressing and a binder applied. The operation lasted one hour and a quarter. Temperature at 12 (midnight) 97°; pulse 84.

March 4th.—9 A.M.: Pulse 90; temperature 96°. The patient has not been sick; expresses himself as feeling quite comfortable. Has had a few teaspoonfuls of wine, water, and milk. Fifteen ounces of urine were drawn off; sp. gr. 1025, acid, no albumen.—3 P.M.: Bowels acted, a copious semi-solid motion being passed.—8 P.M.: Bowels acted again.

5th.—12.30 A.M.: Pulse 96; temperature 99° in mouth. He complains of great thirst; liquids increased, and to take a little barley-water as well.—8.30 P.M.: Temperature 98·8°. Slept several hours. Pulse 100. He has some bronchial catarrh, probably due to ether. Ordered steam inhalations.

6th.—Wound dressed. Total absence of inflammatory swelling; slight serous, inodorous discharge; no tenderness. Evening temperature 100°.

15th.—The patient since last note has steadily improved; temperature normal; pulse 84; bowels acted well, and wound granulating freely. Drainage-tubes have been considerably shortened, and the patient is sitting up in bed, going on remarkably well.

CITY OF LONDON INFIRMARY.

CARCINOMA OF THE LIVER WITH GREAT CONTRACTION OF THE STOMACH, PRODUCING NO SYMPTOMS; NECROPSY; REMARKS.

(Under the care of Mr. W. GEM.)

GEORGE K——, aged fifty-six, a porter, was admitted into the infirmary on October 29th, 1884, suffering from fistula in ano. His condition on admission was pale and anæmic, with great debility and weakness, although no emaciation was apparent; there was a rather copious discharge from the fistula, which was situated an inch and a half up the bowel. He had faint dulness on deep percussion over the left apex of the lung, but no complaint as regards the abdomen, which was enlarged. The liver dulness somewhat exceeded the normal, and was slightly irregular on the surface, but with no pain or uneasiness. He had a little diarrhœa, which was soon stopped by an astringent mixture. He was placed on a nutritious diet and got slightly better of the discharge and debility, but still complained of lassitude. Operation on the fistula was deferred until his condition became more favourable. Not having improved after being under treatment for a month, he was again thoroughly examined, and on percussion over the liver complained of pain over the right hypochondrium, with irregular masses slightly increased. All through there was no vomiting or jaundice. The bowels again became free, but were stopped by lead and opium pills. His history, by the way, indicated no hereditary cancer; he was of temperate and regular habits, and had always done his work as a porter without any feeling of illness except the fistula, which troubled him at times. About a month before his death he complained of pain over the right hypochondriac region, increasing slightly, but not to any extent, and a sense of weight and fulness over the epigastrum, but still no vomiting or jaundice occurred. It was only a few days before death that he showed the unmistakable cachexia of cancer, and emaciation became very great, though he still took his food up to the last, without any trouble or vomiting. He gradually got worse, and sank on January 14th last.

The autopsy was made twenty-four hours after death, and revealed the following. The liver appeared double the size of normal in outline, weighed nine pounds, was nodulated on the surface, with flat tuberous masses of cancer of the encephaloid type, and was soft in consistence. The gall-bladder was normal in appearance, and contained four drachms of bile. There was, of course, great displacement of the neighbouring viscera. The stomach was contracted so as to be a mere tube of half an inch in diameter. The kidneys were slightly atrophied and granular. The left apex of the lung contained some tuberculous masses. The heart was normal, likewise the other organs and viscera. The abdominal cavity contained a small amount of bile-stained fluid; the fistula was slightly cartilaginous half an inch above the anus, and there was a small cancerous nodule of the head of the pancreas of the same type as the liver.

Remarks by Mr. Gem.—The above is interesting inasmuch as cancer of the liver usually gives rise to pain, jaundice, and gastric disturbance, or symptoms of various import, which were conspicuous by their absence here, and usually causing a patient to seek relief before they have caused such great destruction and reached such a stage as in this case. There were nominally no symptoms suggestive of cancer until two or three weeks before death, although it was suspected all through, and no jaundice or vomiting, although the stomach was so contracted and the liver substance so destroyed. The case also shows that it is not incompatible with life for the organs to be in this state. The query arises, How were the functions of the liver and stomach carried on under such conditions?

LEICESTER INFIRMARY AND FEVER-HOUSE.

ACUTE HYDROCELE; PLEURISY AND PERICARDITIS; DEATH; NECROPSY; REMARKS.

For the following case we are indebted to Mr. C. J. Bond, house-surgeon.

George W——, aged sixty-five, a hedge-cutter, first felt sharp pain in the right tunica vaginalis five days before admission; this was followed in a few hours by rapid swelling, so sudden indeed that the patient thought he was ruptured. Two days later he complained of pain in his chest, with some shortness of breath, and gave up work. On his admission, three days later, there were loud friction-sounds over both sides of the chest, with signs of consolidation of the lower part of the left lung. The right tunica vaginalis was distended with fluid, and very tender. No enlargement of the testicle could be detected. The patient died three days later from the pneumonia and rapid pericarditis.

At the autopsy both pleuræ were found covered with thick layers of recent lymph, but containing very little fluid. The left lung showed consolidation of the lower lobe in the stage of red, passing in parts into that of grey, hepatisation. The pericardium contained two ounces of semi-turbid serum, and both surfaces were covered with recent lymph. The right tunica vaginalis contained about two ounces of clear serum, and the surfaces were coated with a layer of recent lymph, a quarter of an inch thick, and having the same naked-eye characters as that on the pleuræ—tough, white, and adherent. The testicle itself was neither swollen nor altered in colour or consistence, and the cord appeared normal. The other organs were healthy, as were also the serous membranes of the peritoneum and arachnoid, and the synovial membranes.

In this case a healthy man (his only previous illness had been an attack of rheumatism one year previously) suddenly suffered, without any blow, inflammation of the testicle, or apparent exciting cause, from a rapid and acute inflammation of the right tunica vaginalis. In forty-eight hours the pleuræ had commenced to take on inflammation of a like nature, and in eight days from the onset of the symptoms the man died from acute pericarditis. No record can be found of inflammation of the tunica vaginalis arising thus in cases of this kind; neither Bransby Cooper, Velpeau, nor Syme mention it in their comprehensive lectures on the subject in the years 1852, 1854, and 1855; so that it would seem to be a rare complication, and the etiology and exact pathology of the hydrocele in this case seems obscure. We are of course familiar with the ordinary hydroceles of children and adults, with the hydrocele arising after inflammation or disease of the testis called by Velpeau acute, but really secondary, and the cases of hydrocele following injury without the testicular implication. But in this case there was a general inflammation of the serous membranes of the body, and in this inflammation the tunica vaginalis takes part. The naked-eye characters, too, of the products of the inflammation, the thick white lymph, and the scanty, almost clear, fluid are alike. Moreover, the somewhat large round organisms described by Friedländer as characteristic of pneumonia were found not only in the pneumonic lung, but also in the pleural fluid, and, what is noteworthy, in that of the hydrocele. Are we, then, to regard the inflammation of the tunica vaginalis as a part of the general inflammation having a common cause with it, a view rendered probable by the absence of any other cause, by similarity of appearance, and the presence of the organisms? If so, in what relation does the pneumonia stand to this inflammation? Was it really the primary affection, and the others secondary, due to an escape, as it were, of the organism? But, supposing this view of the hydrocele to be correct, is it not strange that, with so many cases of pleurisy, the tunica vaginalis is so rarely, in fact never, affected. It might be supposed that the man was suffering from some form of septic poisoning, and that the hydrocele was really a secondary process or pyæmic abscess; but this is unlikely, because there were no symptoms of septicæmia, the temperature was the continuously high temperature of pneumonia, there were no rigors, and especially because the fluid in all the cavities was clear serum, and the lymph white and tough, quite unlike the appearance of any septically-inflamed serous membrane or pyæmic abscess.

PATHOLOGICAL SOCIETY OF LONDON.

Displacement of Lumbar Vertebræ.—Cerebral Arteries in States of Congestion.—Hypospadias.—Destructive Disease of the Lung.—Acute Ulceration of Colon.—Cyst growing from the Wall of the Intestine.—Cases of Gastrostomy.

An ordinary meeting of this Society took place on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair. The number of card specimens exhibited was very large.

Mr. Arbuthnot Lane read a paper on the Modifications which the Lumbo-sacral Articulation undergo as the result of transmission of superjacent weights through it to the pelvis in labourers. He found that the changes varied within broad limits, having at one extreme those cases in which the centre of pressure fell behind the body of the fifth lumbar vertebra; in the other extreme the centre of pressure fell somewhat in front of the body of the last lumbar vertebra, so that there was a marked tendency to forward displacement of it, which was opposed by the articular processes of the vertebra. In this case the spinous processes did not share as they did in the first set of cases in supporting or transmitting the weight to those of the sacrum, which were proportionately to the bodies but slightly developed. Mr. Lane has now found two remarkable modifications of the lower part of the spinal column resulting from pressure. The first of these presented most of the changes characteristic of the first group referred to above. The spinous processes and laminæ of the sacrum were enormously enlarged and were very dense. The bodies were small and cancellous in structure. The body of the fifth lumbar vertebra was displaced backwards, producing a condition diametrically opposite to that called spondylolisthesis. The second specimen, although appearing to belong to the second class of pressure changes, was perceived on vertical median section to belong to the first class. The subject from whom it was taken was a man who had carried heavy burdens on the left shoulder, back, and neck. The lumbar spine was very convex and presented the appearance of spondylolisthesis. On section the last fibro-cartilage was seen to be increased in depth, so that the weight had been transmitted to the sacrum chiefly through the spinous and articular processes, which were very much thickened and increased in strength. The sacrum had yielded transversely about its centre, the upper part going forwards and downwards, so much so that if the plane of the upper surface of the sacrum were continued forward it would pass one inch below the lower margin of the symphysis. The diameters between the angle of the sacrum and the upper and lower margins of the symphysis were three inches and a half. The spinous processes of the sacrum were much enlarged, as were the laminæ. The sacrum had during the later period of life been acted upon by an upward pressure, probably due to a continuous sedentary position. This position had served to increase the anterior concavity of the sacrum still further.

Dr. Handfield Jones showed specimens of Cerebral

Vessels in states of Congestion. Some of the specimens were taken from cases of meningo-cerebritis, but others came from subjects who died from no special disease. He described capillaries obstructed by large leucocytes which were not nuclei of the capillary wall, for they were more numerous and rounded, and changed shape under pressure and stained better than these. The leucocytes probably collected during the last hours of life, and this appearance was well seen in a specimen of omentum; the red corpuscles were not to be seen in the area of aggregated leucocytes. He also described specimens in which there were many more and bulkier corpuscles than those above referred to. Growth of pre-existing cells or accumulation of white corpuscles might explain the appearances. In some specimens cells $\frac{1}{2000}$th of an inch long were to be seen elongated, with their long diameter placed parallel to, across, or obliquely with the vessel; some were free in the channel of the vessel; these might occur in large groups. He did not think that they were endothelial particles, but looked on them as proliferating muscular nuclei. Other corpuscles which appeared to be quitting small arteries, capillaries, and veins were described, and the amœboid qualities of corpuscles were referred to as having been manifested in tissues outside the vessels of the pia mater. Again, rounded or short ovoid corpuscles which were probably overgrowths of portions of muscle nuclei were described. Dr. Jones thought we should distinguish between the muscle fibre and the muscle nuclei; the former may disappear whilst the latter hypertrophy. He then made some remarks on these states of corpusculation, and gave the different views which might be held to explain the occurrence of masses of similar corpuscles. In some of the specimens the capillary walls were sometimes very indistinct. These changes could be witnessed in inflamed areas, where the capillaries appeared fluffy and granulous at times. It seemed as though the vessels were converted into soft granulous matter. Mention was made of small films of unstained protoplasm which could be detected in the neighbourhood of the vessels. Other appearances of a wide meshed plexus of fibrin were described as to be seen in arteries and veins of the cerebral tissues. He considered that many of the appearances were best explained as overgrowths of muscle nuclei with detachment and escape owing to denudation of the vessel wall. There might be a formation and accumulation of corpuscles within the vessels as well as overgrowth of corpuscles. These changes had been met with in cases of meningitis and typhoid fever and other states of cerebral congestion, but they were not necessarily morbid, as they might be found in subjects dead from any cause.

Dr. WILLCOCKS exhibited a specimen of Hypospadias in a seven months' child. The sex of the child was supposed at first to be feminine, and she was christened "Rebecca." There was a slight depression, which was a sort of a rudiment of a vagina, situate between the urethra and the anus. Nodules, which were obviously testes, were felt in the apparent labia. Mr. Symonds drew back the central preputial fold and exposed a minute glans penis. The penis gradually increased in size. The patient died at the age of ten months from the sequelæ of measles. At the autopsy, the male organs of generation were readily recognised, and there was no uterus or vagina. The left obliterated hypogastric artery could not be found. This was a case of mistaken sex. Another was mentioned as having been under Mr. E. Owen's care at the Hospital for Sick Children, Great Ormond-street; this child up to the age of sixteen months was regarded as a girl. Another case of Dr. George Buchanan's was referred to.—Mr. R. J. GODLEE said that he had seen an almost similar case at the North-Eastern Hospital, but there were no testicles on the apparent labia, and there did appear to be a rudimentary vagina.—Mr. J. H. MORGAN had seen cases of the kind under discussion. Sometimes the external organs were those of the female and the internal organs those of the male. Otto had described in the sheep a case of genuine combination of male and female parts, but he was uncertain whether this mixture had ever been observed in man.—Dr. WILKS believed John Hunter had pointed out that when the testes did not descend the physical frame had a feminine configuration.—Dr. BRISTOWE narrated the case of a supposed Welshwoman who became a nurse at St. Thomas's Hospital. She had a beard and moustache, and walked and talked like a man; the parts concerned were preserved in St. Thomas's museum. He doubted whether any genuine combination of sexes ever existed.

Dr. PERCY KIDD exhibited two specimens of Destructive Disease of the Lung from Obstruction of the Main Bronchus, and gave the following history of the patients. In Case 1, a man, aged thirty-eight, who had had syphilis twenty-three years previously, came into the hospital with signs of aneurysm of the aorta and consolidation and excavation of the left lung; the left radial pulse was smaller than the right. He had a paroxysmal cough, and expectorated nummular purulent sputum. His left arm was noticed to become œdematous. At the post-mortem examination a large aneurysm was found involving the descending aorta and compressing the left bronchus and, to some extent, the trachea. The aneurysm was very thin-walled, and contained a small thrombus at the posterior aspect, where it was attached to the spine. The right lung was healthy. The left lung was large and of equal size with the right, riddled throughout with cavities situated in pigmented fibroid tissue, and intersected by numerous bands of a similar tissue. The cavities had a bronchiectatic appearance in some instances, and all contained reddish puriform liquid and some soft caseous material. The liver, spleen, and intestine were slightly amyloid. In Case 2, a married woman, aged twenty-five, had cough, pain in the chest, dyspnœa, night sweats, and wasting; she had no kind of sore-throat or skin eruption; her fingers were clubbed; there was a large circular ulcer on the left thigh, with scarring and pigmentation over the leg. The left chest was dull and almost motionless, vocal fremitus weak, and bronchial breathing and pectoriloquy were noted. There was a paroxysmal cough, and the sputa were nummular. Puncture gave a negative result. She died from albuminuria and general dropsy. At the autopsy there was extensive scarring of the trachea involving the left bronchus, which was much constricted. The left lung was riddled throughout with trabeculated cavities, separated by fibroid lung; the lung was bronchiectatic in some parts. The contents of the cavities consisted of a reddish fluid and some putty-like material. There was recent tuberculosis in the other lung. The other viscera showed amyloid changes. In both cases the sputum was examined for tubercle bacilli without success. He referred to Dr. Pearson Irvine's cases, and thought the specimens shown supported the views put forward by that gentleman, that the breaking down of the lung was due to the pressure on the bronchus, and stagnation of air and secretion in the bronchi.—Dr. CREIGHTON inquired for a history of syphilis in either case, and suggested this agency as a cause of the pulmonary disease.—Dr. GOODHART spoke of the ulceration of the bronchus at the seat of pressure. He thought there were stages in the disease of the lung from fibrous and solid down to caseation and destruction. He suggested that the presence of ulceration might have led to some infection of the pulmonary tissues.—Dr. EWART said that in cases of collapsed lung as the result of pressure on a bronchus he had found no trace of ulceration. Causes might act from within and produce destruction, for inside the air-tubes there might be retention of secretion followed by decomposition and ulterior changes.—Dr. F. SEMON said that Pearson Irvine, as well as he himself, had always found ulceration of the bronchus opposite the seat of pressure of an aneurysm.—Dr. EWART said that was true, but he referred to ulceration from pressure of the pulmonary tissues, and thought that Dr. Goodhart spoke of these tissues, but the last-named gentleman said that he had spoken of the bronchus.—Mr. GODLEE asked whether there was any analogy between the changes and those observed after "cut throat" where it was probable that the accumulation of secretions was the efficient cause of the pulmonary disease.—Dr. HALE WHITE considered that the amount of pressure on the bronchus might explain the differences observed in different cases.—Dr. BRISTOWE did not feel certain that the destructive changes were not antecedent conditions to the pressure on the bronchus. In a case of meningitis in an adult supposed to be tubercular there were signs of cavities in one lung; the autopsy showed no tubercle, but the cavities in the lungs, smooth lined as they were, had no doubt originated early in life. Again we must be sure that no pressure existed on the vessels before attributing the destructive changes to pressure simply on the bronchial tubes for these might communicate later on with cavities formed as the result of vascular obstruction.—Dr. PERCY KIDD, in reply, said that the aneurysm was probably of four years' duration in the first case, and the stricture had lasted one year and a half in the second case. Pressure on the vessels could not be excluded in the first case, but could be in the second. He did not think there was primary syphilitic disease of the lung though, as he had stated, syphilis was mentioned in the history of each case. The mechanical effects of obstruction of the tubes he believed should be charged with the chief part of the causation; there was no collapse of the lung in either case.

Dr. ALLCHIN showed a specimen of Acute Ulceration of the Colon. The patient was a middle-aged woman, admitted into Westminster Hospital on Jan. 4th. 1885, where she died eleven days later. She had been married nine years, and had had five children; had worked hard as an ironer. She had suffered much from constipation, and had passed blood occasionally. Acute symptoms began on Dec. 27th, 1884, about six weeks after confinement; there were pains and diarrhœa of distressing character. On admission she looked very ill and was emaciated. There was a white furred moist tongue. The pulse was 112, soft and dicrotous; the temperature was 101°. There was total suppression of urine, with anorexia and thirst. The pulse gradually became more rapid, and the excessive diarrhœa continued; the temperature varied between 99° and 102°. There was much pain and tenderness about the colon and some tympanites; the urine was not albuminous. The motions varied much in appearance; the colour of them was grey and yellow, and mixed with blood, and sometimes they looked like dark fluid blood, but small globules of mucus were always present. At the necropsy, made twenty-six hours after death, Dr. Allchin found the colon to be the only part diseased; it was slightly congested externally, but there was no peritonitis. There were numerous large ulcers with their long diameters transverse to the axis of the bowel; they had a clean base which was not thickened; the edges were thick and vascular, and in places undermined. The ulcers varied in size from an inch and a quarter to one line in length, and were extensively distributed over the large intestine. The subjacent muscular tissue was laid bare in many of them. No dilatation or hypertrophy of the intestine existed. The case belonged to that class which had been described as "follicular ulceration of the colon." Reference was made to many points of clinical and pathological importance. The symptoms may be very slight in such cases, and the only symptom present may be great irregularity of the bowels. He considered that the cases were not quite like those of acute dysentery. The question as to why the solitary glands were the primary seat of inflammation was broached; as the same structures exist in the small intestine, it is difficult to see why they should not be affected also.—Dr. WILKS made reference to the medico-legal aspect of such cases, and said that Dr. Copeland and others had expressed the opinion that such cases could not occur in this country, and so, when such changes were seen, an irritant poisoning would be diagnosed. He did not share that opinion.

Mr. BATTLE exhibited a Cyst removed from the wall of the Small Intestine. The patient was a married woman, aged thirty-five. Eight years before admission to St. Thomas's Hospital under the care of Dr. Bristowe she had had an attack of jaundice, accompanied by ascites and swelling of the legs; the jaundice disappeared in two years, but the dropsy endured five or six years. The swelling of the left side of the abdomen was observed when the dropsy subsided. She had suffered for eight years from periodical bilious attacks. The tumour was tender at the menstrual periods. The patient was anæmic and well nourished. There was a rounded swelling in the left hypochondrium, immediately below the costal arch, the size of a large egg, movable, but not with respiration; it was tender and painful. In the hypogastrium was another swelling, hard, also tender and somewhat movable, smooth, and extending from the left side of the middle line into the right iliac fossa. Three months after admission Mr. Sydney Jones removed the cyst by abdominal section; it was found to be attached to the small intestine, being sessile, and occupying a considerable section of the intestinal wall, to which it was firmly attached, and from which it was carefully peeled. A few vessels required ligature, but the thermo-cautery was required to arrest the general oozing from the intestine. There was a varicose and dilated condition of the lymphatics on the surface of the intestinal folds. The pelvic tumour was a uterine fibroid. The operation was performed antiseptically, and the patient made a good recovery, leaving the hospital thirty-seven days later free from pain and in improved health. The tumour was smooth on the surface and the size of a small orange, white and glistening. It had a laminated wall, but there was no evidence of glandular structure nor of epithelial lining. The fluid was thick and looked like yellow paint. Cholesterine crystals, fat, and molecular matter were found by the microscope, and fat and albumen by chemical examination. —Dr. BRISTOWE did not think it was a hydatid tumour.

Mr. BRUCE CLARK showed two specimens removed from two cases of Gastrostomy. In one case the obstruction was situate low down at the cardiac end of the œsophagus, and in the other it was situate high up in the gullet. A successful operation had been performed in both. In the first case the stricture was pervious and the stomach was not contracted. This contrasted with the other case, where the stomach was greatly contracted and the stricture was impervious. In the latter case bile was discharged from the gastrostoma. This proved to be due to the opening having been made to the duodenal side of the pyloric orifice; the incision was made well to the left of the rectus, but the contraction of the stomach no doubt caused the awkward position of the opening. One patient lived seven weeks and the other six weeks; both died from asthenia.

The following card specimens were shown:—Mr. Godlee: a recent specimen of Acute Necrosis with Pericarditis and Large Patches of Softening of the Left Ventricle. Dr. Norman Dalton: Multiple Angiomata of the Liver. Dr. C. Turner: (1) Tumours in Adrenals; (2) Suppuration of Simple Fracture of the Hyoid Bone. Dr. Silcock: Enterocolitis. Dr. Goodhart: Specimens of Enteritis and Colitis. Mr. J. Hutchinson, jun.: Hydrocele of the Cord. Dr. Hebb: Aortic Valvulitis with Embolism of a Coronary artery and Middle Cerebral Artery. Mr. Shattock: Fracture of Superior Cornua of Thyroid Cartilage. Dr. Chaffey: Solitary Kidney (congenital). Dr. Hale White: (1) Enormous Hypertrophy of Heart; (2) Large Triple Phosphate Renal Calculus. Dr. G. N. Pitt: Syphilitic Ulceration of Larynx and Trachea. Dr. Hadden: (1) Broad Ligament Cyst containing Coagulated Albumen; (2) Ulceration of Intestine originating in hæmorrhage. The patient was leucocythæmic.

MEDICAL SOCIETY OF LONDON.

Treatment of Gangrenous Intestine in Strangulated Hernia.

AN ordinary meeting of this Society was held on Monday last, Dr. W. Miller Ord, F.R.C.P., President, in the chair. A well sustained discussion followed the reading of the paper.

Mr. MITCHELL BANKS read a paper on the Treatment of Gangrenous Intestine in Strangulated Hernia. The author dealt with two main propositions. The first was the consideration of the question whether the surgeon should leave the gangrenous gut where it was, merely incising it and awaiting the formation of an artificial anus. The second was the consideration of the question of excision of the sloughing bowel and restoring the continuity of the intestine. A case illustrative of this second method of procedure was narrated. On Nov. 7th, 1883, a cook on board ship, aged twenty-five, was admitted into the Liverpool Royal Infirmary for strangulated inguinal hernia of the right side, which came on three days before as the result of exertion; the strangulated bowel could not be returned, and when admitted all the symptoms of strangulation were well marked. Previous attempts at reduction had been made and the hernial tumour had been aspirated, but without avail. On the third day of strangulation the pulse was 80, and there was no fever; the scrotum was livid, swollen, and tense, with bullæ under the skin; the penis was œdematous, and the parts had the appearance rather of rupture of the urethra than of strangulated hernia. An incision was made and the sac dissected out. The hernia was found to be a congenital one. A great deal of dark bloody fluid and a long loop of the *small intestine*, which was swollen and black, with a few flakes of lymph thereon, were found in the sac; the peritoneal coat was dull, and an offensive sanguineous fluid drained away. The removal of the dead intestine was decided upon, and division of the stricture was practised. An ulcerated aperture, due to a stricture higher up, was found, but no blood was extravasated into the peritoneal cavity. In the operation a wedge-shaped piece of mesentery was removed, and gave rise to profuse bleeding, which was controlled by the application of a score of fine catgut ligatures. The peritoneum of the mesentery was united by a continuous suture of catgut, first on one side and then on the other.

Then the edges of the gut were turned inwards for a third of an inch, so that peritoneum should come against peritoneum; the mucous coats were united by interrupted sutures, and continuous sutures were used outside these and through the peritoneum only. The method was that of Czerny-Lambert. The inguinal canal was freely divided to allow of the reduction of the intestine. Then the sac was secured by two catgut ligatures and divided between and excised, the lowest part being left to form a tunica vaginalis. The operation lasted altogether two hours, and antiseptics, with drainage-tubes, were used. The collapse passed away in a few hours, and the patient passed flatus ten hours after the operation. The temperature seldom rose one degree above normal, and was for some time after the operation several degrees below normal; a temperature of 100° was the highest reached; the tongue was moist throughout, and the abdomen flat. The portion of the sac left became slightly sloughy, where it formed the tunica vaginalis, but this soon healed. Sponge dressings were used. The man was of placid temper, and showed great fortitude, lying quietly on his back without restlessness for one week. For four days only ice was sucked by the mouth; then some twenty minims of meat-juice were allowed, and the dose of this was increased slowly. Nothing more was given by the mouth until the twelfth day, except a little opium. Absolute rest and warm clothing were insisted upon, and served to prevent waste of tissue. On the twenty-third day the bowels acted after an enema. At the end of six weeks the man was well, and ate plain food. He was in robust health some months later, and seventeen months after the operation he was in a situation in Canada, and there was no reasonable fear of stricture of the intestine supervening. The author then gave an account of statistics, and quoted especially a paper of Mr. Makins, in which 55 cases of gangrenous intestine were tabulated; 45 of these were resected, and gave a mortality of 29 deaths, or about 52 per cent. Death was generally attributed to septic peritonitis. Most of the cases were operated on by German surgeons. A few had been recorded by English and American surgeons. Of 40 cases of resection of the bowel for the relief of artificial anus, there was a mortality of 38 per cent., as against 52 per cent. above mentioned. With regard to the first question, he narrated 6 cases of gangrene which had been under his care, and in which the gangrenous gut was simply laid open, the stricture being left untouched. Of these 3 lived and 3 died; two of the latter were moribund when operated on, and the third died as the result of rupture above the stricture. He thought that there could be no doubt as to the propriety of slitting up the bowel, but it was another question whether the surgeon should interfere with the stricture. Sir Astley Cooper and others advised division of the stricture, but he believed that the best method was to leave the stricture alone. He said the cases did not die from general septic peritonitis, but from absorption of septic material from the peritoneal cavity. He likened the stricture to a rigid ring on the finger, and thought the methods of treatment should be the same in the two cases. As to drawing down a fresh piece of intestine into the abdominal opening, he thought it could be done without dividing the stricture, but would wait for practical experience to say whether the drawing down of fresh intestine was a good mode of procedure. He concluded by asserting his belief that the number of cases in which primary resection of the gangrenous gut could advantageously be performed would be found to be comparatively few.

Mr. FREDERICK TREVES thought that primary resection should be performed in a large series of cases, and he failed to see what great surgical difference there was between excision and incision of the gangrenous gut. There were two methods of dealing with the case after excision had been performed. The surgeon might leave the case till an artificial anus had formed, and then attempt to close the false anus or resect the bowel later on, or he might restore the continuity of the bowel immediately after the excision of the gangrenous portion. The length of time required for the latter operation was a serious element in the case. From a series of experiments on resection of the intestines in dogs, he had come to the conclusion that there was great risk of the parts sloughing if the mesentery were cut so that the main arteries going to the loops of vessels in the mesentery were divided. He preferred Chinese twist to catgut for sutures. In Littré's hernia the stricture ought not to be divided.

Sir WM. MAC CORMAC agreed with Mr. Banks that immediate excision of the gut was not likely to be performed in a large series of cases. He also concurred in the view that the stricture should not be divided.

Mr. MORRANT BAKER also thought that excision and immediate union of cases of gangrenous gut could be but rarely carried out. He narrated a case of acute gangrenous strangulated hernia. He had not yet made up his mind as to the question of division of the stricture, although, following the teaching of his seniors, he had usually carefully divided the stricture. He did not regard with favour the pulling down of fresh bowel.

Mr. JOHN H. MORGAN referred to the difficulty of being sure of removing all the gangrenous gut, for the parts around the actual slough might be in a state of incipient gangrene. He considered that the best practice was the ordinary one of leaving the gangrenous gut *in situ*. An artificial anus could be dealt with later on.

Mr. MAKINS still held to the conclusions at which he had arrived in his paper to which reference had been made. He still thought that a clamp was an advantage in resecting the intestine, which should, however, be a secondary and not the primary operation.

Mr. A. PEARCE GOULD was of opinion that any further drawing down of the intestinal loop would, by increasing the thickness of the stalk of mesentery, lead to a further spread of the gangrene to the fresh bowel drawn down unless the stricture were divided.

Mr. BERNARD PITTS considered that the duration of the strangulation was an important element in deciding on primary or secondary resection; where the strangulation had lasted a long time resection at the time would be most unfavourable.

Mr. WALTER PYE spoke of an increased strain on the mesentery due to a further drawing out of bowel. He referred to a case of gangrenous intestine in which he had established an artificial anus. During exertion the open bowel slipped into the abdomen and caused the death of the patient from peritonitis.

Dr. ORD spoke of the valuable practical discussion which the excellent paper had brought forth.

Mr. M. BANKS, in reply, said that Mr. Treves' recommendation of cutting off the sloughing part, dividing the stricture, and pulling down fresh bowel was practically what Mr. Spence used to advise.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of the above Society was held on Wednesday, April 1st, Dr. J. B. Potter, President, in the chair.

The following specimens were shown:—Dr. Galabin: Fibro-sarcoma of the Chorion; Dr. John Williams: Papilloma of the Peritoneum; Preparations of the Injected Uterus, showing the Circulation; Microscopic sections.

The following papers were read:—

Sequel to a Case of Ovariotomy.—Dr. MURPHY removed a large cystoma of the left ovary from a multipara on January 16th, 1882, and, finding the right ovary enlarged and the seat of cystic disease, he passed a double ligature underneath it, and, having firmly secured the ligatures, punctured the cysts and removed portions of the ovary. The patient made an excellent recovery, menstruated on the third day after the operation, and was regular for nine months, when she became pregnant and gave birth to a healthy male child on June 9th, 1883. The possibilities of a third ovary and the slipping of ligatures were considered and rejected. Attention was directed to the erroneous drawings of the relative positions of tubes and ovaries usually given in the text-books. The author believed that the ovary was usually found superior and posterior to the tube, and hence the tube escaped being ligatured, and the ovary survived (as does the distal portion of the stump) and was able to perform its functions in that diseased and mutilated condition. At the date of the report there is no appearance of a cystoma of the *right* ovary.—Dr. HERMAN said that there were two points of interest in Dr. Murphy's paper. One was the position of the ovary in relation to the Fallopian tube. The arrangement described by Dr. Murphy had been also described by Mr. Doran in his recent book, and Dr. Herman had himself seen this arrangement. The other point was the effect on the blood-supply of the ovary produced by ligature without removal of the ovary. Professor Simpson had done this in a case recorded in vol. ix. of the Edinburgh Obstetrical Transactions, but as this was followed by an attack of peritonitis three months later, it was less instructive than Dr. Murphy's case, which seemed to prove that simple ligature could not be depended on to arrest the function of the ovary.

On the Circulation in the Uterus, with some of its Anatomical and Pathological Bearings, by Dr. John Williams.—The author remarked that although the blood-supply to the uterus is well known, the circulation in the uterus has been less minutely studied, though its importance, both physiologically and pathologically, is great. After briefly sketching the course of the ovarian and uterine arteries as they approach the uterus, the author remarked that all the primary branches enter the uterus on the side; they do not enter deeply into its tissue, but run a somewhat superficial course, being separated from the peritoneum by only a thin layer of muscular fibres. They run in a distinct and even a considerable layer of connective tissue, which is more distinct in the fœtus and infant than in the adult. The muscular stratum between it and the peritoneum is thin, while that between it and the canal forms the greater part of the thickness of the uterine wall. The branches run towards the mucous surface in a perpendicular direction to that surface, anastomosing freely, and ending under the mucous surface in capillary loops, which are often visible even in organs which have not been injected. The veins in the organ are arranged in a similar manner, and convey the blood into the venous plexuses which lie with the arteries in the layer of connective tissue already mentioned, and which communicate freely with the venous trunks outside. The return of blood is said to be effected principally through the ovarian veins; but both these veins can be (as is well known) tied without appearing to materially affect the return of blood from the uterus; indeed, the whole of the pelvic venous system can be injected through any one of its larger trunks. The following conclusions were drawn:—1. The layer of connective tissue in which the arterial circles run, and in which the venous plexus lies, is the submucous tissue of the uterus. 2. The whole thickness of the wall between the layer of connective tissue and the uterine cavity is the mucosa uteri, and the thin layer of tissue shed at the menstrual period and reproduced (the menstrual decidua) is only a very small portion of the uterine mucous membrane. 3. The vascular arrangements are such that the circulation in the uterus can hardly be disturbed by mechanical causes. The entrance and exit take place at numerous points at the sides of the uterus, and in the uterus the direction of the current is transverse to its length and perpendicular to its surfaces; so that a ligature might be placed around the uterus at any point above the vaginal insertion without affecting the circulation above or below. The only ligature which could materially interfere with the flow of blood into or out of the uterus is one surrounding each broad ligament, including their upper borders, together with a portion of the uterus. Conditions like these are found when the uterus forms a hernia in the inguinal canal or in Douglas's pouch in the condition usually, but inadequately, spoken of as retroflexion or retroversion. Both conditions are those of true hernia, and the symptoms are largely due to constriction at the neck of the sac, formed, in posterior hernia, by the sacro-uterine ligaments. In procidentia, again, stretching of the vessels may produce considerable narrowing of their calibre. These two conditions, hernia of the uterus and great procidentia, appear to be the only displacements of the uterus which can give rise to congestion of that organ. The author also described the following experiment to test the influence of flexions in causing congestion. He stitched the fundus of the uterus closely to the cervix, thus securing the acutest flexion possible, and then injected a coloured fluid into one of the veins of the broad ligament; immediately the veins of the other side of the uterus became distended with the injection. On making a section, the whole of the veins in the uterus were found injected. This proves what the arrangement of the vessels has already shown, that the acutest flexion does not interfere with the flow of blood from the uterus. The paper was largely illustrated by diagrams and specimens.—Dr. Graily Hewitt was not surprised at the elaborate arrangements existing in the uterus for providing for free circulation when the organ was flexed. Flexions were doubtless common, and the vascular arrangements were secure against temporary or slight flexions. But in severe or sudden flexions there would be much danger of congestion at the two ends of the uterus. Such congestion occurred in the limbs when bent. His experience was that congestion in cases of flexion was relieved by straightening the uterus, and hence the explanation suggested itself that compression at the central part produced the congestion. He believed incarceration of the fundus by the sacro-uterine ligaments to be extremely rare. Even if it were commoner, it had no bearing on anteflexion, in which there were no ligaments to cause incarceration. Swelling of one lip of the cervix often indicated flexion on the side of the swelling, and argued for the production of congestion by flexion.—Dr. Herman pointed out the great frequency of flexion without any symptoms. That flexion was often combined with congestion depended on the frequency of flexions, and must be the case unless flexions prevented congestion. There were cases of sudden backward displacement with acute symptoms, quickly relieved by replacement, which had no analogy in anteflexion. There were also cases of retroversion without flexion, attended by congestion, and relieved by elevation of the fundus. Such cases were not explained by any theory of flexion, while they were explained by the action of the sacro-uterine ligaments; they were not common, and incarceration in Douglas's pouch was rare, because the ligaments were seldom tense enough and close enough together to be capable of incarcerating the uterus; when they were, they were generally high up and hard to reach.—Dr. Galabin said that the author had proved that the vascular arrangements in the uterus were such as to prevent as much as possible congestion in cases of flexion. He thought the influence of the sacro-uterine ligaments was overrated by Dr. Williams. It was rare to find them constrict the fundus in retroflexion, and rare to find the uterus go up suddenly on reposition, as ought to occur in such cases. There is often evidence of congestion in excessive menstruation in cases of retroflexion, and the symptoms were often relieved by a pessary. In most cases the utero-sacral ligaments had only a minor effect; the stretching and twisting of the broad ligaments, and possibly the flexion itself, ought to be considered. The transverse arrangement of the vessels might be expected to prevent congestion everywhere except opposite the bend. He thought that in the section of the fœtal uterus shown by the author he saw some longitudinal as well as transverse vessels. In procidentia, as the cervix was extruded it became congested, even without any apparent constriction at the vulva. He did not agree with Dr. Herman that the frequent occurrence of anteflexion without congestion proved that flexion could have nothing to do with congestion. Acquired flexion might possibly produce congestion for a time, but the circulation would soon re-establish itself.—Dr. Champneys pointed out that the arrangement of the vessels in the uterus was very similar to that in the intestines, which the uteri of many animals greatly resembled. The intestines were marked by acute flexions every few inches, but no harm to the circulation resulted from them in the case of the intestines, and it was unlikely that the result would be different in the case of the uterus. He thought that congestion was often diagnosed on insufficient grounds, and, indeed, in most cases congestion of the fundus was impossible of verification. Careful examinations made him think that the influence of the sacro-uterine ligaments was rare. In cases of retroflexion with profuse menstruation the influence of descent had to be remembered; it had repeatedly happened to him to lift up the fundus with a pessary, to find the symptoms relieved, and the uterus, high up, indeed, but as much flexed as ever.—Dr. Aust Lawrence (Clifton) said that very few cases of displacement were uncomplicated. He could only remember three such cases of retroflexion of this nature; all these went to prove that the displacement was competent to produce profuse menstruation, and therefore congestion. The first case was that of a single woman aged twenty-two, who was thrown from a cart; the next period was excessive, and he found acute retroflexion and incarceration by the sacro-uterine ligaments. It was replaced, and the bleeding ceased, the next period being normal. The other two cases were similar, with the exception of incarceration.—Dr. Murray agreed with Dr. Williams; although there are cases of congestion with flexion, there are many flexions without congestion. Menorrhagia may occur without flexion. Prolapse of the uterus would tend to produce congestion by impeding the circulation.—Dr. W. Duncan thought that congestion of a retroflexed uterus was not un-commonly due to incarceration by the sacro-uterine ligaments, especially when thickened and shortened by inflammation. Thickening of the posterior cervical lip did not prove an impediment to circulation by flexion, as it was common without any flexion. Many cases of congestion in flexed uteri can be cured without treating the flexion.—Dr. WILLIAMS regretted that there had been no discussion on the doctrine enunciated in the paper that the whole thickness of the uterus within the connective tissue in which the vessels ramify (described above), should be considered to be mucous membrane, this connective tissue being the submucous coat. The muscular layers inside this, therefore, are really the "muscularis mucosæ," into which the uterine glands penetrate. The submucous coat is plainly seen in the fœtus, and also in some conditions in the adult, as the specimens shown illustrate. Dr. Hewitt's illustration from a flexed limb presents no analogy; a flexed finger would have been more apposite, and a finger is often permanently flexed, but no congestion results. Dr. Hewitt believes that congestion will not result from a temporary but from a permanent flexion; Dr. Galabin believes exactly the opposite. Dr. Hewitt's argument from clinical observation requires careful examination of crucial cases, disturbing influences being excluded, such as pregnancy, which is itself capable of producing congestion. Only cases where no pregnancy or disease has ever occurred will serve as arguments. In such cases Dr. Williams had never found congestion follow flexion. Dr. Aust Lawrence's first case confirmed the views stated in the paper; the other cases were not related in sufficient detail to use as arguments. In some cases replacement of the uterus arrests, in others it produces, hæmorrhage; indeed, as Dr. Robert Lee pointed out, a simple vaginal examination in a healthy woman may produce hæmorrhage.

Note on a Case of Absence of the Uterus and Occlusion of the Vagina, by Dr. BOUSQUET (Marseilles).—The patient, aged twenty, had never menstruated, but had suffered from hæmorrhages at the usual periods, sometimes from the rectum, sometimes from the gums, lasting four or five days. When seen, the hæmorrhage had lasted two days; the gums were swollen, painful, and bled on touch. The hymen was very hard; from a small hole in its centre flowed whitish mucus. The hole was enlarged upwards and the finger inserted, but only penetrated two centimetres, where it met a second membrane, tympanitic on percussion. This was incised and the finger penetrated three centimetres further, but no cervix could be felt. Combined examination by vagina and rectum discovered no uterus. The author then cited a very similar case of Dr. John Clarke's in St. George's Hospital, followed by an autopsy in which ecchymoses were found in the skin, pleuræ, and pericardium, together with old endocarditis. The author regarded these cases as proof that the ovarian nisus is sufficient to cause vicarious menstruation when the natural channel is absent.—Dr. JOHN WILLIAMS did not think either of the cases were examples of vicarious menstruation, but of purpura in women without uteri. Histories of periodical bleedings or periodical fits were to be received with much caution. He had watched several such cases in hospital for four or six weeks, and found either no bleeding or fits, or bleeding or fits at irregular intervals.—Dr. ROUTH related a case in which the vagina was too short, and the introduction of the whole hand into the rectum proved the absence of a uterus. This was the only certain way of making the diagnosis. He agreed with Dr. Williams that the case was one of purpura in a malformed woman, rather than one of vicarious menstruation.—Dr. CHAMPNEYS said that women were apt to attribute any unusual hæmorrhages, whether with amenorrhœa or not, to some menstrual influence. It was his habit to make such patients keep a diary of their hæmorrhages and monthly periods. Such an exercise was often sufficient to effect a cure, and in his experience it had invariably sufficed to explode the theory of vicarious menstruation. He agreed with the former speakers as to the nature of this case.—Dr. AMAND ROUTH related the case of three sisters, aged twenty-five, twenty-two, and twenty, who had never menstruated. In the two younger the vagina was only two inches long; in one, recto-abdominal examination proved the absence of uterus and ovaries, in the other the uterus was a nodule the size of a filbert. There was no vicarious menstruation. The breasts and pudenda were childlike. A younger sister, aged seventeen, was quite healthy and menstruated regularly. All the three sisters were very anæmic, and were said to be consumptive.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Pathological Section on February 13th, Mr. WHEELER read notes of a case of Gangrene of the Leg and Occlusion of the Popliteal and Tibial Veins in a man aged forty-six, of intemperate habits, who had twisted his leg whilst wrestling. When admitted to hospital the leg was swollen, hot, much discoloured, and with large sanguineous bullæ. He was quite free from pain. The specimen exhibited showed well-formed thrombi occluding the interior and posterior tibial veins, there being the several example of the "obliterating," the "valvular," and the "parietals thrombus; the wall of the vein in the first case being much thinned. Allusion was made to some of the recent theories of coagulation of blood.—The PRESIDENT remarked that the specimens being so dry, it was impossible to tell whether or not there had been any inflammation, but his intemperate habits and the bruise or twist went a long way to explained what occurred.—Dr. M'ARDLE said the twist would have sufficed to tear the inner coat of the vein, which would have led to the formation of a clot sufficient to cause occlusion.

Mr. BROOMFIELD exhibited and explained a specimen of Endocardial Concretion which was taken from an old woman aged seventy-eight. Being a dissecting-room specimen, he had no history of the case. The specimen was of a calcareous character and interesting from its exaggeration, extending round four-fifths of the mitral orifice and running three-quarters of an inch into the ventricular wall. At one point there was complete rigidity. The endothelial lining was perfectly healthy, and the valves were comparatively healthy. It was curious that such a calcareous zone should have formed round the valves without implicating them or causing incompetence. There was no appearance of any other cardiac lesion.

Dr. M. A. BOYD exhibited a Colon removed from a man aged thirty, who died in the Mater Misericordiæ Hospital with all the symptoms of tropical dysentery of a month's duration, having had the usual fetid stools, containing mucus, blood, and shreds of lymph and mucous membrane, with most distressing tenesmus; a dry, brown tongue, dryness of the throat and difficulty of swallowing, vomiting, and hiccough. The temperature throughout, except in the beginning, when the attack came on with shivering and hot skin, was either normal or subnormal. There was tenderness over the liver; no enlargement of spleen and no peritonitis. The descending colon could be felt through the abdominal wall, round, resisting, and tender. The autopsy revealed not ulceration of rectum and colon, but general thickening of the mucous coat of the colon throughout, with exudation upon it of an adventitious lymphy membrane. From the close resemblance of the symptoms to dysentery, many of the so-called cases of dysentery were in reality cases of croupy or diphtheritic disease of the colon.—The PRESIDENT regarded the specimen as a good example of diphtheritic enteritis. There was an absence from it of the fetor which was characteristic of dysentery. Sometimes casts of the entire bowel formed by the membrane were passed.—Dr. LENTAIGNE inquired if there was much superficial tenderness, and if any member of the man's family had similarly suffered.—Dr. HENRY KENNEDY, referring to his extensive opportunities of seeing cases of dysentery in 1847-48, said he had seen the whole bowel from the stomach to the rectum covered with croupy exudations, giving rise to symptoms analogous to those produced by ulceration. A physician to the Queen, who had published an account of a violent epidemic of dysentery in Millbank prison, had recommended mercury as a most effectual remedy.—Dr. BOYD, in reply, said tenderness of the abdomen was absent, except along the descending colon. The family history was good, all the patient's family being healthy.

Dr. LENTAIGNE exhibited an example of Aneurysm at the Base of the Brain, which was taken from a woman who, whilst putting a postage stamp which she had just bought on a letter, fell dead in the shop, as if struck by lightning. Up to the time of her death she had been apparently in perfect health. On post-mortem examination he found a large quantity of blood, effused at the base of the brain, which had come from an aneurysm about the size of a pea, formed in the middle cerebral artery at its junction with the posterior. The artery was split open with a large rent. There was no disease elsewhere, save that the kidneys were small and contracted. Almost all the vessels of the brain were atheromatous, but the aorta was perfectly free from atheroma. A great deal of blood was wedged in below the medulla and spinal cord. The stomach was full of tea and undigested potatoes.—The PRESIDENT observed that the compression of the medulla by the effused blood was no doubt the cause of death

Mr. ABRAHAM read a paper for Dr. NIXON on Pericarditis in a Horse, showing a specimen. The principal features were enormous hypertrophy and an extraordinarily extensive fibrinous exudation covering the whole pericardial surface. The usual weight of the horse's heart was 6 or 7 lb., but this specimen weighed 21 lb. The notes of the case were taken by Mr. J. Kenny, V.S., under whose care the horse had been for pleuro-pneumonia, which had yielded to treatment. A week after the animal was brought back with high pulse and friction-sounds over the heart, subsequently becoming dull. At the post-mortem examination four gallons of yellow fluid were obtained from the pericardium. The hypertrophy of the heart was of long standing, and caused chiefly by the heavy work which the animal had to perform. The pericarditis appeared to be secondary to the pleuro-pneumonia. The immediate cause of death was the enormous pericardial effusion.

After a short discussion the section adjourned.

The opening meeting of the Sub-section of Anatomy and Physiology was held on February 19th, when the President, Dr. D. J. Cunningham, expressed his sense of the honour done him in electing him to the chair for the session; an honour which he prized highly, not only in being considered worthy of succeeding such men as Dr. Macalister and Dr. Purser, but also on account of the great interest which he had all along taken in this department of the Academy.

Mr. BROOMFIELD exhibited his patent Eustachian valve, also a model for showing to a class the changes in the crystalline lens during accommodation.

Dr. BENNETT exhibited a facile method of demonstrating Alternation of the Sectors of the Crystalline Lens of the Eye to a class by injecting ether into the posterior side of the capsule of lens, or between the vitreous humour and retina, a small quantity of mercury which formed a bright reflecting surface, the shape of which depended on the surrounding tissues. The results obtained by the mirror posterior to the vitreous humour appeared to give the best results. He stated that for a successful demonstration an eye not too fresh and a top light are desirable.

Mr. M'ARDLE read a paper on a case of Anomaly of the Arch of the Aorta. The branches derived from the transverse portion from right to left were: right carotid, left carotid, left vertebral, left subclavian, and right subclavian. The only ones having a peculiar course were the right carotid and right subclavian. The former at its origin was somewhat to the left of the trachea. After ascending for half an inch it passed directly to the right, in front of the sixth and seventh rings of the trachea, and then upwards on the right side of that structure. The subclavian came off from the posterior aspect of the arch on a level with the remains of the ductus arteriosus; thence it passed in from off the second and third dorsal vertebræ, and behind the trachea and œsophagus, so that these structures were compressed between it and the foregoing vessel. The only other peculiarity of this trunk was its cone-shaped origin, where it was at least half as large as the aorta. It diminished to the normal size before giving off a single branch.—The PRESIDENT said the case which Mr. M'Ardle had so well described was one of the commoner varieties met with in the dissecting-room of the anomalous arrangement of the aortic branches. It was one of the most interesting of all the anomalies, because at first sight it appeared to be very difficult of explanation. The difficulty, however, at once disappeared on close examination. It had been shown lately that the anomaly was associated with the transference or transposition to the right side of the thoracic duct. This was explained by supposing that the thoracic duct, like the aorta, was laid down in the form of two lateral tubes, which afterwards fuse. It was interesting to notice the relation of the laryngeal nerve, because the fourth arch, counting from above, was obliterated, and therefore it was not recurrent at all, having nothing to hook round. There were about five cases on record of the transference of the thoracic duct to the right side. These were given by Drs. Crookshank, M'Donnell, Brown, and Arthur Thomson of Edinburgh.

Dr. BROOKS gave a description of an Anomalous Coronary Branch arising from the Pulmonary Artery. The case occurred in an old female subject in the dissecting-room of Trinity College, Dublin. The abnormal branch arose from the left anterior sinus of Valsalva of the pulmonary artery; it was rather under an eighth of an inch in diameter, and its branches ramified chiefly on the infundibulum of the right ventricle, a few small ones supplying the coats of the pulmonary artery. Both the normal coronary arteries were present, and were rather large.—Dr. PURSER observed that as there was free anastomosis it must have carried arterial blood, and must have acted as a vein. The blood must have flowed from the point of high to the point of low pressure.—Dr. BROOKS, in reply, said the anastomosis was tolerably defined in one part. He had no doubt some of the arterial blood must have travelled on account of the high pressure. Still the communication did not seem to be sufficiently free for the whole of the blood to go that way.

The PRESIDENT communicated a paper which he received from Professor SHEPHERD, of Gill College, Montreal, on Musculus Sternalis in an Anencephalous Fœtus. In six such specimens Professor Shepherd had found the anomalous muscle, and in five of these he had been able to make out its nervous supply to be the same as that of the pectoral group of muscles.

Dr. BROOKS related a case of the Vena Azygos Major ascending on the Left Side, and discussed the bearing of this Anomaly on the Develepment of the Azygos Bloodvessels. It occurred in a male subject, and appeared to be a transposition from right to left of the normal arrangement. The vein ascended on the left side of the bodies of the dorsal vertebræ, receiving the left intercostal veins, with the exception of the first and second, and also a branch from the right side, which entered it at the level of the eighth dorsal vertebra, and was formed by the confluence of two veins, which lay on the right side of the bodies of the vertebræ; the superior of these two received the sixth, seventh, and eighth intercostal veins; the inferior collected the blood from the ninth, tenth, and eleventh intercostal spaces. The left azygos thus formed attained to the size of an ordinary azygos major; it crossed the junction of the transverse and descending portions of the aortic arch, and opened into the left innominate vein. A small vein opened in the ordinary position of the (right) azygos major; it was formed by the confluence of four intercostal veins, but the trunk lay not in the ordinary position of the azygos major on the bodies of the vertebræ, but on the ribs external to the gangliated cord of the sympathetic. This peculiar position was interpreted as representing a larger portion of the posterior cardinal vein persisting than usual. A remarkable bend in the course of the left azygos, whereby a portion crossed the necks of the tenth and eleventh ribs, was explained in the same way. Reference was made to the symmetrical condition of the venæ azygos in the embryo as affording a ready explanation of the transposition—the right, instead of the left, azygos system having been broken up.—The PRESIDENT remarked that this anomaly was also of interest from a comparative anatomy point of view, because in some of the lower animals it was the normal arrangement for the vena azygos major to pass up the left side, the opposite to that in the human subject. In the sheep this was the case. In marsupials it sometimes chooses the one side and sometimes the other. The Tasmanian wolf was an example of its passing up the right side, as with ourselves.

The PRESIDENT gave a description of an Andaman Skeleton, and compared it with those of other races. He referred to the two elaborate papers which had been communicated by Professor Flower to the Anthropological Institute upon the osteology and affinities of the Andaman islanders, and showed how closely the skeleton in his possession bore out the many remarkable facts described by that author. He especially directed attention to the lower jaw, vertebral column, and the sternum. He compared the lower jaw with that of a European child of five years old, and showed how closely they resembled each other. In both the feebly marked chin, the poor development of the basal or subdental part of the body, the low ascending ramus, and shallow coronoid notch were very manifest. The cervical vertebræ were distinguished by their spinous processes exhibiting very little tendency to bifidity. The bodies of the lumbar vertebræ were not moulded in such a fashion as to give any assistance in the formation of the lumbar curve; in fact, the sum of their anterior measurements was considerably less than the sum of their posterior measurements. The sternum was remarkable for its extreme narrowness, but this is a feature which the author considered might possibly be an individual peculiarity, as he had had no opportunity of examining this bone in other Andaman skeletons, and Professor Flower had not mentioned it in either of his papers. The author concluded by stating that Professor Flower had unquestionably put his finger upon the salient point in connexion with the Andaman skeleton when he called attention to the many infantile characters which it exhibited.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on March 12th.

Leucocythæmia.—Dr. DYSON introduced a patient with Splenic Leukæmia. He was about forty years of age, married, and a blade-forger. He says he was healthy up to his present illness. There was no history of alcoholism, syphilis, or ague. The illness commenced five months ago, with wasting, loss of strength and appetite. There was no pain, and no history of hæmorrhage. He lost 2 st. in weight. Since his admission to the public hospital there has been pyrexia, the temperature ranging from 99° to 102° F., and quick pulse. The abdomen is half filled with the enlarged spleen, which presents the usual characteristics. Bronchitis was present on admission, and there were profound anæmia and œdema of the legs. Systolic hæmic murmurs were heard at the base of the heart, and white corpuscles were greatly in excess in the blood; red, paler, and forming rouleaux imperfectly; also smaller corpuscles, very highly refractive and spheroidal. One observation of the urine gave in twenty-four hours 62 oz. and 446·4 grs. of urea; no albumen or sugar. The treatment pursued had been quinine, iron, and arsenic, internally, and the constant galvanic current externally.

Aortic Stenosis.—Dr. BANHAM introduced a boy aged eleven years, suffering from aortic stenosis. There was some hypertrophy of the left ventricle, and indeed the compensatory changes in the heart were complete, so that no cardiac symptoms were complained of. The chief peculiarity in the case was the exaggerated character of the systolic murmur and thrill, both of which had been noticed by the child's parents. The murmur could be heard not only all over the chest, but throughout the whole length of the spine and over the occipital bones, and also when the ear was withdrawn an inch or two from the front of the chest wall. The thrill, which was excessive over the upper part of the chest and in the large vessels, was recognised the moment the hand was placed on the boy's shoulder. There was no evidence of aortic dilatation, the second sound of the heart was not generally audible.

Epilepsy.—Dr. PORTER read a paper on Epilepsy. After reviewing briefly the theories which had been put forward to explain the phenomena of an epileptic fit, he quoted from notes of twenty cases which had come under his treatment among a total of 841 out-patients at the Sheffield Public Hospital and Dispensary last year. Of these, eleven were males and nine females; in three cases there was a family history of epilepsy, in two of insanity, and in four of other nervous disorders, making a total of nine out of twenty cases in which there might be inferred hereditary tendency to brain affections. The fits occurred for the first time, in a very large proportion of these cases, either between ten and twenty years of age, or after thirty. As the exciting cause, two cases were attributed to head injuries, four to sudden shock or mental troubles, one to onanism; two originated with pregnancy, one at the commencement of menstruation, and one at the menopause. In reference to the connexion between epilepsy and uterine neuroses, Dr. Porter referred to Prof. Charcot's description of so-called hystero-epilepsy, and contended that in those cases at all events in which the hysterical and epileptiform paroxysms occurred together, the epileptic characters were *more* simulated than real; he deprecated the use of the term "epilepsy" in the nomenclature of this class of affection. In six cases out of twenty Dr. Porter met with a distinct aura, and in four more there were distinct premonitory symptoms. In enumerating the drugs he had found most serviceable, he laid special stress on hydrobromic acid in drachm doses; sodium nitrite he considered a very dangerous drug, from what he had seen of it in epilepsy. Dr. Porter considered that the proposal to introduce such an operation as the ligature of the vertebral artery in epilepsy should be received with the greatest caution.

Reviews and Notices of Books.

The Local Government and Public Health Orders relating to Urban and Port Sanitary Authorities, &c. By R. CUNNINGHAM GLEN, Barrister-at-Law. London: Shaw and Sons.—It is well known that the Local Government Board have, in their Poor-law and sanitary capacity, issued a considerable number of orders, circulars, memoranda, and sets of instructions, and that a number of the former have the force of law; some also have been repealed or cancelled; and as regards others, it is not always easy to decide whether they are or are not the ones which remain in force. Under these circumstances, the issue by Mr. R. C. Glen of a volume containing all such valid documents, arranged in proper order and carefully indexed, supplies a real want, and the work cannot fail to be of considerable service. Every subject as to which orders have been issued will be found to be included, and some of the orders, such as those relating to the constitution, &c., of joint hospital boards, cannot, without a great deal of trouble to those seeking them, be found elsewhere than in such a volume. In short, as a work of reference Mr. Glen's book will doubtless find a place in the libraries of many who are engaged in administering sanitary and Poor-law matters in this country.

Eczema and its Management: a Practical Treatise based on the Study of Three Thousand Cases of the Disease. By L. DUNCAN BULKLEY, A.M., M.D., Physician to the New York Skin and Cancer Hospital, &c. Second Edition. New York: G. P. Putnam's Sons. London: J. and A. Churchill.—The perusal of the second edition of Dr. Bulkley's considerable work on Eczema shows that he has spared no pains to make his views quite clear, and the work generally a thoroughly practical one. The previous edition was received with much favour, and in this second issue the author, whilst not altering in any way the principles of theory or practice, has made considerable additions and revisions with excellent judgment. General practitioners, for whom the work is more especially intended, will find in it a clear and trustworthy guide in the treatment of a very common and often embarrassing disorder. We may mention that Dr. Bulkley's views closely correspond with those held by Wilson and Fox in this country.

The Hunterian Oration delivered at the Royal College of Surgeons of England, Feb. 14th, 1885. By JOHN MARSHALL, F.R.C.S., F.R.S., LL.D., Past President of the College. London: Smith, Elder, and Co. 1885.—Our readers are already familiar with Mr. Marshall's excellent Hunterian Oration, for it was published in full in our columns immediately after its delivery; but we are confident that they will welcome this reprint, especially as it is enriched by some useful references and notes. The Hunterian orator has a difficult task, for he addresses a critical audience familiar with the many excellent deliverances of past orators; but Mr. Marshall undoubtedly succeeded in imparting freshness to the theme in his discussion of the connexion between recent advances in surgical and histological knowledge and the views of John Hunter. Often as the Hunterian festival comes round, we feel afresh that the life and labours of this great father of scientific surgery are worthy of far more attention than they have yet received, and we welcome any addition to our knowledge of the man and his work.

The Asclepiad. No. 6, Vol. II.—Readers of the *Asclepiad* are now familiar with the general construction of this periodical, and we believe that not the least welcome feature is the account, always interesting and faithful, of some man of mark. The current number is rich in illustrations, and a portrait is introduced with the object of adorning the biographical notice of the anatomist, Vesalius. In the Opuscula Practica Dr. Richardson brings forward a new remedial agent which he believes will play as useful a part in surgery as the ethylates and colloids have already done. This agent is oxalic ether, which is too heavy to be administered by inhalation, though it may be applied hypodermically. It coagulates the albuminoid structures and produces a "free and dry eschar," without any marked constitutional disturbance. It promises to be of service in the removal of morbid vascular growths. The other contents of this number are—the Hygienic Treatment of Pulmonary Consumption; Measures of Vital Tenacity; the Prescription for Alcohol in Disease, a chapter in which we find ourselves almost in complete accord with Dr. Richardson; Researches on Resuscitation from States of Suspended Life. Altogether the present number is a very good one.

Nature's Hygiene: a Systematic Manual of Natural Hygiene. Containing also an account of the Chemistry and Hygiene of the Eucalyptus and the Pine. By C. T. KINGZETT, F.I.C., F.C.S., late Member of Council, Institute of Chemistry of Great Britain and Ireland, &c. Second Edition. London: Baillière, Tindall, and Cox.—Mr. Kingzett, in his second edition, has revised and enlarged his interesting and useful book. He has now divided it into two parts, of which the first deals with general considerations, such as the chemistry of natural oxidation, theories of disease, water-supply, sewage-disposal, antiseptics, and the like; while the second is devoted to the branch of chemistry which the author has made peculiarly his own—namely, the oxidation of the essential oils, particularly those of the pine and the eucalyptus, and the efficacy of their products of oxidation as antiseptic agents. Naturally a considerable portion of this part of the book is given to the consideration of the "Sanitas" preparations invented, or we might more properly say discovered, by Mr. Kingzett, but the treatment throughout is strictly scientific, and there is no trace of the trade puff. There is, indeed, great scientific importance in the facts which Mr. Kingzett has brought to light in regard to the development of peroxide of hydrogen during the oxidation of essential oils. It explains the hygienic value of pine and eucalyptus forests, and, we may add, of "Sanitas," which now enjoys general favour as a disinfectant, safe, pleasant, and useful, although, perhaps, not very powerful.

Syllabus of Lectures on Physiology delivered at Guy's Hospital. By P. H. PYE-SMITH, B.A., M.D. Pp. 110. London: Churchill. 1885.—This little work contains a large amount of information admirably adapted for the students of Guy's Hospital in attendance on Dr. Pye-Smith's lectures, but of less value to those who are taught elsewhere; nevertheless, there is much that is suggestive not only to students, but to teachers. The text consists of a series of short notes such as a lecturer might bring into the lecture-room with him, or which an intelligent student might jot down, when studying his text-book, for the purpose of refreshing his memory. The notes do not, and are not intended to, give details, but simply supply headings which the student might advantageously think and write out at length. The diagrams, of which there are many, are quite original and well worthy of study.

Zigzag Ramblings. By R. T. MANSON, M.R.C.S.—This little volume consists of a republication of a series of papers contributed to the *Darlington Times*, and they well deserve the wider circulation they are likely to enjoy by being issued in a separate form. The book reminds one of Gilbert White's "Natural History of Selborne," containing as it does descriptive sketches of the physical aspects and features of Darlington and its vicinity, given in an easy and attractive style. To the residents of the locality, especially, the *brochure* cannot but prove an agreeable coompanion during a stroll along the hedgerows and through the lanes and copses of that part of the north of England. Familiar lessons in botany and geology, interspersed with entomological and meteorological facts and references, with the introduction here and there of quaint axioms and moral reflections, make up a very readable little book, which is worthy of a somewhat better dress than that in which it is presented to the public.

SUPPOSED POWER OF ACCOMMODATION IN AN APHAKIC EYE.

To the Editor of THE LANCET.

SIR,—I think that the facts reported in Mr. Bickerton's case, published in your issue of March 21st, can be explained without supposing that the eye possesses any power of accommodation. It is well known that the retinal images need not be formed with absolutely mathematical accuracy in order that vision may reach the standard which is usually accepted as the normal one; it is also an accepted fact that the larger the retinal image, the less do the circles of diffusion interfere with vision. A difficulty in choosing between lenses differing from each other by less than 1 D is, I should say, rather the rule in testing the distant vision of cataract patients after operation. In testing the near vision, also, there is always a range extending on either side of the point for which the glass employed adapts the eye, which extends, I believe, further on the proximal than on the distal side of that point. I have no precise data as to its extent, but am convinced that it usually comprises several inches. In the present instance, the refraction, being 10·5 D + 14 D, would adapt the eye for a point 11·3 in. from the glass; the range, therefore, was slight on the distal side, but reached 4·8 in. on the proximal.

I fail to understand Mr. Bickerton's meaning when he says that "on either side of our strictly mathematical focus for near objects (p.p.) there is a small range of space in which we can see." The *punctum proximum* (p.p.) is the point for which the eye is adapted when using its maximum accommodation; the range, therefore, on the distal side of this extends to the "far point" (p. r.)—i.e., in the normal eye to infinity. The range on the proximal side of p.p. is greater when, as in Mr. Bickerton's case, there is a lens before the eye, because the images are then somewhat larger. As long as the distance of the lens from the eye is insignificant as compared with the distance of the object, as is the case in distant vision, the difference in the size of the retinal images is inappreciable, but when the object is brought within a few inches it becomes considerable. I think that Mr. Bickerton fails to appreciate the fact that the power of reading 1 Jaeger at 9 in. does not indicate a very high degree of visual acuity. The height of the letters being 0·75 mm., they would have to be held at a distance of 16 in. to give the same size to the retinal image that occurs in seeing $\frac{20}{30}$. The really extraordinary point in Mr. Bickerton's case, as reported, is that his patient had a visual acuity which was double the normal standard. I have not referred to this earlier because I suspected the statement that vision was $\frac{20}{10}$ to be a misprint. If Mr. Bickerton really intended to convey this, the case is, as far as I know, unique; and it is to be hoped that he will publish further particulars in reference to it, stating particularly the exact height of the letters used, their exact distance from the eye, the number employed, and the number read correctly.

I am, Sir, yours truly,

W. ADAMS FROST.

Wimpole-street, March 23rd, 1885.

P.S.—Since writing the above I have examined a patient, aged thirteen, on whom I operated, in January for lamellar cataract in one eye. With + 11 D the visual acuity is $\frac{20}{70}$. With + 15 D he reads 1 Jaeger over a range extending from 11·4 in. to 5·75 in. (measuring from the lens). Of course he reads best at the distance for which the glass adapts the eye—viz., 10 in. This, for some unexplained reason, was not the case with Mr. Bickerton's patient. I do not think that this range is in the least usual; were it so, many patients would in some respects be better off before the operation than after the most brilliant result.

THE LANCET.

LONDON: SATURDAY, APRIL 25, 1885.

A VERY important financial experiment is at this moment threatening, the effect of which, if it were successfully carried out, would materially tell upon the profession of medicine. It is said that a Life Assurance Company is about to be formed the leading feature of which is to be that all necessity for a medical examination of the insured shall be dispensed with. The statement of the person about to insure will be put to a severe test. He or she will have to affirm the state of health, at the moment of commencing the contract, on a form so explicit and binding that anyone who intentionally deceives will inevitably have to forfeit all benefit. It is thought, we must assume, that each insurer will himself take care, by a medical examination, that he is certain before he insures; and that in this way the usual fee paid by the companies for a private medical report, as well as the fee paid to the medical officers of companies, will be entirely saved.

There is about this proposed experiment just sufficient plausibility to induce many men to give it a trial. There is no part of human action so truly and so rashly experimental as the financial. Men of business, as they are called—those who pride themselves on being called men of business, and who chide everybody who does not come up to their rigid standard of business ability and punctuality,—are often amongst the first to enter on a speculation which to them seems certain, because, on the surface, it presents no irregularities which they care for. It is well known, too, that on all insurance boards there are directors who are ready to accept every case that comes before them, and who would, on the doctrine of chances, accept every case, barring those which were self-condemned, if their more cautious colleagues did not keep them in check. It is therefore anticipated that a sufficient number of capitalists may be found to embark on the new project, and, "throwing physic to the dogs" in the most open fashion, take the risks of life against money into their own hands.

There is yet another reason for supposing that this scheme may for a time float. It is well known that of late years the existing companies have one and all, *as if by unconscious* unity of action, become more and more particular in their selection of lives. There exists, as a consequence, at the present time an enormous uninsured community, the members of which have tried to insure and have failed to carry out their wishes. These still wish to insure, and a new company starting, as it were for their benefit, would find a constituency ready to its hand. At first, too, the scheme might seem to be financially sound, and for one or two years a fair balance of profits might reward the enterprise.

It is well to take a calm survey of all these matters, and so, from its very inception, look the project fairly in the face. It is well, also, on the principle "forewarned, forearmed," to endeavour to detect what fallacies lie at the root of the new proposal. There are so many fallacies that we have no space in one article of this kind to bring even a moiety of them forward; but one or two should be named at once. It would, then, be a fallacy to assume that the design could be possibly successful with any capital that is at present represented by even the richest of the existing assurance offices. If all the companies were to club together into one great society, we think it doubtful if the plan would or could, in the long run, succeed. The value of medical examinations and of medical services does not rest on rough-and-ready statements as to the general health of would-be insurers, but on those refinements of examination which the people in general do not even think of. On the one hand, there are numbers of nervous people who imagine they are about to die, or, at best, will not live long, though they have little organically wrong with them, but who, if they were left to themselves, would never insure in any company to which they had to make a solemn declaration of health. On the other hand, there are multitudes who are ready at any moment to insure, and, disbelieving all statement as to their danger, would insure at once, if they had the power to do so, with nothing but their own evidence to help them into the insurance. Broadly we might divide all who insure into these two classes, and it is in regard to them both in this broad or general sense that the profession comes in most usefully for the protection of certain of them, and for the protection and advantage of all the companies. The doctor, in fact, as things now are, is the man who insures the mere nervous insurer, while he is the man who does not insure the bad reckless insurer, who at all risks would offer himself if he knew that he must be accepted. This point in favour of the present system carries with it in practice the greatest confidence in those offices which maintain the principle of selection of the fittest most determinately. An office that has the credit, or discredit, of accepting all fish that comes into its net is the office most distrusted. Such an office has been, as a general rule, the office that has most frequently failed; and where it has tried the plan and found it wanting, it has been the one which has had most trouble in disposing of its policies and in freeing itself from its troubles.

We content ourselves at this stage with what we have said above. We have given the profession the earliest intimation of a project which affects its honour, its integrity, and its interests. We have indicated the conditions under which the project may find means to offer itself for trial upon the public, and we have noticed the first grounds on which the project is likely to fail. For whatever else may come of the design we shall watch and wait.

◆

"WHAT is the meaning of this mysterious dispute between the coroner and the doctors? It has been going on, as occasional indications have shown, for a long time—a sort of smouldering fire, sparks glowing here and there in a heap of wood ashes. Yesterday it broke out in a blaze in the coroner's court, and flamed so fiercely that we almost wonder nobody sent for the fire-engines. What does it all mean? There is something about post-mortem examinations—so much we know; and something about fees; and something, too, about hospital doctors, between whom and the coroner there appears to be a deadly feud of some unexplained character." With these words the *Birmingham*

Daily Post, one of the best conducted and most influential provincial journals, commences one of its leading articles on the 18th inst.

The mere fact that in so populous and important a community as Birmingham the relations of Her Majesty's coroner and the medical profession are, on good authority, said to be in a state of chronic conflict, points to a condition of things deeply affecting the public interest. So grave is the actual and possible issue, that we have instituted careful inquiries on the subject.

The office of coroner in Birmingham has a remarkable history, only one vacancy having occurred in it in something more than half a century. For upwards of forty years Dr. John Birt Davies, then senior physician to the Queen's Hospital, was the Birmingham coroner; leaving a record of enlightened and laborious industry almost unparalleled. He only retired on reaching fourscore years; and his merits were somewhat lightly passed over, in the heat of the discussion which attended the appointment of his successor. The relative claims of medical and legal coroners were not seriously discussed, and the Town Council of Birmingham, with whom the appointment rested, decided to bestow it on a distinguished member of their own body, Mr. Alderman Hawkes, a solicitor in leading practice, who had twenty years previously filled the office of Mayor, and had given abundant proof of intellectual attainment and public spirit. He had not long been in office before he instituted two most important and beneficial reforms—the establishment of public mortuaries, and of a central coroner's court, where inquests have ever since been held, instead of at public-houses, as was previously the practice. Unfortunately, at a very early stage in his new career, matters did not run smoothly between the coroner and some of the members of the medical profession, especially so in the case of juniors on the resident staffs of the local hospitals. The sore has not healed with friction; and the contest of the other day appears to have been a test battle between the coroner and a junior of exceptionally high qualification, so placed as to give him apparently some technical advantage over paid residents, who, one after the other, have had to succumb. Dr. William Arthur Foxwell, the gentleman in question, having held the offices of pathologist and resident physician to the General Hospital, was recently raised by the committee of governors to the position of assistant physician, and is now in practice as a physician in Birmingham. Under these circumstances he seems to have been under the impression that, in appearing before the coroner, he was no longer compelled to give unpaid evidence, as he was, by law, during his residence in the hospital. When called by the coroner to state the cause of death, Dr. Foxwell asked for his fee, whereupon an altercation ensued, which we summarise from *Aris's Birmingham Gazette* of the 18th inst., the report in which is in substantial agreement with those of the other local papers:—

"Dr. Foxwell asked for his fee, and said he was not now on the resident staff.—Mr. Hawkes: Do you decline to give evidence?—Dr. Foxwell: I am not resident in the hospital. —Mr. Hawkes: I ask you again, do you decline to give evidence?—Dr. Foxwell: I am not now resident in the hospital. I have travelled all the way from Alvechurch to give evidence at this inquest, and think my expenses should be paid."

If in expressing this opinion the physician was in error, it was open to the coroner to correct him; and everyone who frequents the superior courts knows with how much kindliness and suavity judges always direct professional juniors, whether in their own or the medical profession. But this seems to have been an occasion for severity and not suavity.

"The coroner then called upon Inspector Willis to prove that he served a summons upon Dr. Foxwell at the General Hospital to give evidence at the inquest.—Mr. Hawkes (handing Inspector Willis a paper): Is that my precept?—Inspector Willis: It is, sir.—Mr. Hawkes: Does it include the name of Arthur Foxwell, assistant-physician at the General Hospital.—Inspector Willis: It does, sir.—Did you serve a summons on the doctor?—I did, sir. On Wednesday afternoon last I received the precept, and I served the summons personally.—What did he say?—He said he was resigning his office the following day, but he would attend."

It was surely rather early to call in the police inspector; but Dr. Foxwell preserved his equanimity, and requested to be allowed to make a remark. So reasonable a request, if met in the same spirit, might have put an end to the difficulty, but the coroner seems to have considered that his court was not the place for explanations.

"Mr. Hawkes: You may make any remark you like before the Queen's Bench.—Dr. Foxwell: The statement is not correct.—Mr. Hawkes then asked Inspector Willis to call upon 'Arthur Foxwell to come forth and save his peril.'—Inspector Willis did so in a loud voice three times.—Dr. Foxwell: The officer did not serve me as stated."

Apart altogether from the merits of the question immediately at issue, it surely was an extraordinary proceeding to meet a physician's request for permission to make a remark by threatening him with the Court of Queen's Bench, and directing a police inspector to call upon him in open court, while he stood there, "to come forth and save his peril." The coroner probably felt that the witness should have stated his objection before he was sworn, and that once he had taken the oath he was bound to answer to the best of his knowledge, protecting himself if he chose by submitting under protest; but the fee question having become the subject of a long altercation, this point was reached.

"Mr. Hawkes: Is your objection to state the cause of death because you have not had a fee for the post-mortem examination?—Witness; I have no authority to do so.—Mr. Hawkes: I must commit you for wilful contempt of the authority of the Queen and this court.—Dr. Foxwell: I am sorry you take things in this way.—Mr. Hawkes (sternly): Officer, take this man in charge.—Dr. Foxwell (wavering): Am I to be detained?—Mr. Hawkes: Certainly. You will be sent to Winson Green [the common gaol].—Dr. Foxwell: Have I no right to speak to anyone outside?—Mr. Hawkes: You can speak to whom you like, so long as you remain in the custody of these officers.—Dr. Foxwell: Can I not obtain legal advice on the matter?—Mr. Hawkes: You can send for a lawyer if you like. I shall be most happy to see him. You must not begin to make extortions in Birmingham merely because you have been practising in London. [To the jury:] If I owed him a guinea he could sue me in the County Court for the money. Did you (the jury) ever see such a miserable exhibition as this on the part of an educated man in a struggle after a guinea. Thank heaven, he is not a Birmingham man."

Dr. Foxwell interposed—"I beg your pardon, sir"; and, after a few more questions and answers, these followed:—

"Mr. Hawkes: Can you tell the jury the probable cause of death?—Dr. Foxwell: Yes; shock. I did not understand what you meant; I could have told you that at any time.—Mr. Hawkes: The cause of death was shock?—Dr. Foxwell: No, sir; I did not say that. The "probable" cause of death was shock.—Mr. Hawkes (sarcastically): After half an hour's trouble we have got this much from the witness—that the probable cause of death was shock.—Dr. Foxwell: That is not——Mr. Hawkes: Pray don't interrupt, sir; don't interrupt me again.—Mr. Hawkes was proceeding in his remarks when Dr. Foxwell again interrupted.—Mr. Hawkes (to Sergeant Gosling): Remove this man from the court.—Dr. Foxwell: That evidence is worth nothing. Shock might be caused by anything.—Mr. Hawkes: Remove him; take him away. We will not be bothered with him any longer. I must resent these insults to the court from members of hospital staffs.—Dr. Foxwell: And I hope that the hospital staffs will resent the insults of the court.—Sergeant Gosling and Police-constable Twigg then escorted Dr. Foxwell to the door."

This is certainly one of the least creditable altercations we ever remember as having occurred in a coroner's court. Conceding that the Birmingham coroner may have been annoyed by the demeanour of the juniors at a particular hospital, it can scarcely be doubted that, on proper representations being made to its managing committee, they would have assisted Her Majesty's officer in the discharge of his highly important duties. But it is not easy to see how such an altercation as that above recorded can conduce to the protection of life or to the dignified administration of justice. An old legal practitioner may naturally have little sympathy with the aspirations and worldly inexperience of a distinguished young scientist, who, even if injudicious (we do not say he was so), yet did not deserve to be treated as a *quasi*-felon. Above all, it behoves legal coroners, if not exceptionally informed on medical matters, to be very careful to obtain accurate medical evidence, and to avoid anything approaching to a conflict with medical witnesses.

◆

Mr. Mitchell Banks read an important and valuable paper at the Medical Society on Monday last on the Treatment of Gangrenous Gut in the operation for Strangulated Hernia; and it was successful in initiating a good discussion. Many months ago Mr. Banks was called upon to operate for a scrotal hernia which had been subjected to considerable violence by the patient's efforts to reduce it. The coverings were greatly swollen and livid in colour, and on opening the sac there was an escape of clot and bloody fluid, and a coil of gangrenous intestine was exposed. In view of the absence of putrid suppuration in the sac and of the good general condition of the patient, Mr. Banks drew down the intestine until he exposed healthy bowel, and then proceeded to excise several inches of the gangrenous intestine with a wedge-shaped piece of mesentery, and to unite the cut ends of the bowel, which he finally returned within the abdomen. The man made a good recovery, and is now well and able to follow his occupation as a cook. This appears to be the first recorded case in which this operation has been successfully performed, and Mr. Banks is to be warmly congratulated upon the success which rewarded his skill and care. This case formed an excellent text for a consideration of the line of treatment to be carried out in similar cases.

The patients who present themselves with gangrene of the strangulated bowel may be roughly grouped into three classes. There are, first of all, those who are in a moribund condition, dying from exhaustion consequent upon the unrelieved strangulation, the vomiting, &c. In these all the surgeon can do is to afford the relief that is to be obtained by a free incision into the bowel and an evacuation of its contents, with the removal of obstruction. In such cases no further treatment can for a moment be considered. Then there is the small class of cases, of which Mr. Banks's is an instance, in which both the local and the general conditions are favourable, where the coverings of the hernia and the sac are not infiltrated with putrid serum or pus, and where the patient's strength is not exhausted by incessant vomiting. The conditions are favourable for recovery, and where assistants and the necessary appliances are at hand, the operation performed by Mr. Banks is indicated. This procedure requires considerable time, and no little skill and care in the complete arrest of hæmorrhage from the divided vessels in the mesentery and in the bowel, and in the careful adjustment and closure of the bowel. A septic condition of the wound will also with almost absolute certainty be attended with a fatal result. The after-treatment requires to be conducted with the greatest care and judgment. Even under the most favourable circumstances, this operation will always involve considerable risk, and it is only the fact that it affords the quickest means of restoring the patient to the best possible condition that justifies the procedure. Between these extremes of cases are others in which the general condition is such as to admit of recovery if the obstruction be relieved, but in which both it and the local condition are such as not to admit of the resection and union of the bowel and its return within the abdomen. In these cases the practice of surgeons has varied, and it was Mr. Banks's object to elicit opinion in such a manner as to make the practice more uniform. One course open—and it was strongly advocated by Mr. Treves—is to excise the gangrenous bowel, and, gently drawing down the ends of the bowel, to unite them to the skin wound and make an artificial anus. Subsequently, when the conditions are all favourable to the operation, this anus can be excised, the ends of the bowel united, and the parts replaced within the abdomen. The argument in favour of this plan is that it at once removes the sphacelus and securely fixes the bowel to the skin, preventing its slipping back and causing fæcal extravasation. The subsequent resection of the anus is a much less dangerous operation than when performed primarily for the gangrene. On the other hand, it is alleged that when the dead bowel is freely incised the sphacelus very quickly melts down and separates; that the disturbances at the neck of the sac may be the means of allowing septic matter to pass into the peritoneal cavity; and, further, that the cutting off of the intestine, if done beyond the sphacelus, must be attended with hæmorrhage; while yet another objection to this plan arises in those cases where the extent of the gangrene is doubtful at the time of the operation.

The alternative plan is to make a free incision into the gangrenous bowel, to evacuate its contents and the fluids infiltrated in its walls, and to make a free passage for the contents of the bowel above, and, having done this, to leave the parts to nature. The slough is very quickly thrown off and a fæcal fistula remains. This may close spontaneously, or may be made to close by such a device as has been described and successfully practised by Mr. BANKS or by some similar means. Or the surgeon may subsequently resect this portion of bowel and restore the continuity of the bowel within the abdomen. The simplicity and success of this procedure will no doubt commend it to the majority of surgeons, and make it the usual course to be adopted in these cases. But in connexion with it the questions arise—whether the stricture should be divided, and whether it is well to draw down obviously healthy intestine into the neck of the sac. Each of these queries should, it would seem, be answered in the negative. The parts about the neck of the sac should be left as undisturbed as possible, for not only may the bowel be greatly thinned and weakened just where it has been nipped by the stricturing band, but the adhesions formed on its inner surface which shut out the peritoneal cavity from the wound may be broken through, and a path opened for the passage of septic matter into that serous sac. As Mr. BANKS rightly stated, septic poisoning, and not peritonitis, is *the* cause of death after operations for strangulated hernia; and in cases where the contents of the sac are septic, as they usually are in gangrene of the gut, no pains should be spared to preserve the adhesions which may have formed about the hernial ring. The surgeon will also, of course, take all the steps that seem to him advisable to cleanse the external wound, and to render the escape of the intestinal contents and effused fluids absolutely unimpeded. If the discussion of this subject result in rendering more certain and clear the lines of practice in this serious condition, which may arise suddenly in the practice of any surgeon, it will have been abundantly justified, and such we believe will be the case.

◆

IT is, we think, imperatively necessary that attention should be at once directed to one most urgent matter in connexion with the public provision for the care and cure—or cure and care, as it ought to be—of the insane. The need of small hospitals for the prompt and active treatment of mental disease is very plain and very pressing. In 1877 the following plan was suggested:—To provide in every district a hospital, properly so called, thoroughly furnished with all necessary appliances for the physical and moral treatment of insanity. Attached to this hospital, so far as the conduct of its general arrangements is concerned, to construct an institution—or if necessary more than one—to which patients not either requiring or likely to be benefited by active personal treatment, but still needing medical care, may be removed when in the course of each individual case it becomes apparent that this transfer will not prejudice the final chances of recovery. In connexion with the workhouse, or in some appropriate institution—for example, a "workhouse asylum"—to provide suitable wards for the senile and infirm, whose recovery is impossible, and who tarry only for death. It was contended that this threefold system being efficiently organised, the necessary circulation of cases might be readily maintained without either indefinitely multiplying costly buildings, or allowing the curative establishment to become blocked against recent and curable cases by the stagnation of chronic cases. There would, moreover be this great advantage in the plan suggested—the capacity of the hospitals required in any district could be determined, not on a vague conjecture as to the probable rate of increase in the total number of pauper lunatics, but upon the more definite, and though neglected not impracticable, basis of the number of persons *becoming insane.* This general scheme was then worked out in detail from the statistics available as follows:—In Middlesex the admissions to the asylums at Hanwell and Colney Hatch during the year 1875 amounted to 1054. The discharges and deaths in the same year were 1044. It was estimated that about 30 per cent. of these case-endings, as they may be called, either by removal or death, occurred *within six months of their admission.* This is a most important consideration. The average number resident in the Middlesex county asylums for the period was 3906, and it was calculated that the actual accommodation required for *new*—that is, recent—cases would not exceed 1000 beds for the whole county. The rest of the accommodation provided was, in fact, devoted to the *care* of the insane, as distinguished from their *cure.* In Surrey, the total admissions in 1875 at Wandsworth and Brookwood numbered 834. The discharges by death or recovery were 568, of which some 30 per cent. took place within six months. The average number resident in the two public asylums of Surrey at that time was 1699. A hospital with 600 beds would therefore, it was urged, suffice for the cure of insanity in that county. Some addition to these computations was made for the new cases sent direct to licensed houses, and then the general inference was drawn thus: One curative establishment—or, better still, two—in Middlesex and one in Surrey, not exceeding the manageable proportion of 600 beds, with an ample medical staff and a sufficiently large number of attendants, would do more to keep down insanity *by curing the highest proportion of curable cases* than the most energetic and skilful use of the machinery at present employed could accomplish. In these small curative establishments it would be possible to make the treatment of each patient an object of special care. The progress of the malady might be watched, the exhibition of appropriate remedies at specific periods would be possible, and *the same clinical observation and research might be brought to bear on the work of cure which are now practicable only in hospitals.*

We reproduce this proposal as meeting the full requirements of the case, and affording an opportunity for the solution of the great difficulty of the moment with regard to the temporary custody of those who are alleged to be insane, but whose actual condition is doubtful. At each of the hospitals provided there would be receiving wards, and to these magistrates might remand cases for observation Attached to such hospitals, also, there would be wards for sleeping purposes only, allowing patients who were sufficiently recovered to "work for their living" to remain under supervision for awhile, going to their homes by day and returning at night, until they were quite fit to be discharged. "Out-patient" departments also would be practicable. In short, there would be the nucleus of a complete development of the hospital system with facilities for the clinical pursuit of mental disease by students of medicine; the net results being to place disease of the mind, so-called, on a footing of equality with disease of the body. This would at once bring the light of day to bear strongly on the subject of insanity and on the care of the insane. We again commend the consideration of this scheme in its entirety to the attention of the Legislature and the profession.

◆

At a recent meeting of the Obstetrical Society of London Dr. John Williams related his researches on the circulation in the uterus. Briefly told, the arrangement of the vessels is the following: The ovarian and uterine arteries run along the sides of the uterus and give off numerous branches, which proceed horizontally inwards and form circles round the organ; from these vessels run towards the uterine cavity in a direction perpendicular to the surface. It results from this that each portion of the uterus has its blood supply secured to it at its own level, and is not dependent upon any segment above or below it. The paper was illustrated by numerous specimens of injected uteri, both fœtal and adult. The arrangement of the veins is similar, and secures a free return of blood; the venous anastomoses of the veins outside the uterus are numerous and free, and it is an almost everyday observation that the ovarian vessels may be tied without embarrassing the return of blood from the uterus in any serious or permanent manner. The paper enunciated new views as to the real nature of various layers in the uterus. According to Dr. Williams, the primary branches of the vessels run in a layer of connective tissue near the peritoneal surface, which is more plainly seen in the fœtus than in the adult, and is really the submucous layer, usually said to be absent. The muscular layer outside this, which is very thin, is the true muscular wall of the uterus, while the whole thickness within the submucous coat is the mucous coat, and the muscular layers in it, forming the chief thickness of the entire wall, constitute the "muscularis mucosæ," into which the glands dip. The "mucous membrane" affected by the menstrual cycle is the "decidua," and is only a very small portion of the mucous coat. These observations derive additional force from a study of the uteri of many of the lower animals, which are thin. The chief practical importance of the paper, however, lies in the assertion of the author that a ligature may be tied completely *round* the uterus at any point above the vaginal injection without affecting the supply of blood either above or below, and that therefore flexions of the uterus can have no effect upon the blood supply, in the way of causing congestion. The mechanical theory of uterine pathology has been subjected to a series of searching scrutinies of late. The researches of *Vedeler and Herman*, already quoted in these columns, have shown that displacements are extremely common, and that their effect on the production of dysmenorrhœa and allied disorders can no longer be maintained. They are now subjected to another ordeal; it is here contended that flexion pure and simple cannot conceivably produce congestion. In the discussion which followed the paper, Dr. Graily Hewitt, the champion of the mechanical system, acknowledged that the vascular arrangements were probably competent to secure an equable supply and return of blood in temporary and slight cases, while in severe and sudden cases congestion was very likely to ensue. Dr. Galabin subsequently took the exactly contrary view that although there might be some obstruction to the circulation at first, collateral circulation would probably soon equalise matters. Dr. Hewitt fell back on his personal experience of cases of anteflexion as well as retroflexion complicated by congestion. Associations of this sort require to be subjected to the most severe and sceptical criticism by the observers who make use of them as arguments. The sense of the meeting appeared to coincide with that of the writer of the paper, and to agree with him that it is still to be explained how a flexion of the uterus pure and simple can conceivably be a cause of congestion. Displacements appear to be getting at a discount. Judging from the results of debates on the subject, our rising teachers neither teach them nor believe in them. When the "spur at the angle of flexion" cannot be produced in the flesh when repeatedly asked for (though figured freely in text-books); when the idea of flexion has been divorced from that of dysmenorrhœa; when the circulation in the uterus is demonstrated, and a theory of the possibility of congestion being produced by flexion is not forthcoming in the face of actual specimens—what remains? We may at least hope that the rising generation will henceforth be fed with facts and allowed to judge for themselves.

Annotations.

"Ne quid nimis."

THE COUNCIL AND THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

We understand that a meeting of the Committee of the Association of Fellows was held on Wednesday last, to consider the latest decision of the Council respecting the alterations proposed to be made in the College Charters. Great disappointment—to euphemise—is felt at the continued rejection of several of the fundamental recommendations of the Association, and at the resolution of the Council not to submit the draft of the new Charter to a general meeting of the Fellows and Members. Indeed a rumour is current that the Committee of the Association regard this decision as directly contrary to a general understanding with the deputation of the Association that such a meeting would be held. Steps are, we believe, about to be taken to arrange a programme and a plan of action which will enlist the sympathy and receive the joint support of the two Associations of Fellows and Members. There should be little difficulty in discovering a *modus vivendi* for the two Associations. If this can be accomplished, the speedy defeat and overthrow of the anti-reform league in the Council is certain. It is important that a combined course of action should, if possible, be agreed upon without delay. The annual election is rapidly approaching, and the Fellows will have an opportunity of giving practical effect to their convictions by refusing to re-elect those who are known to have resisted every movement for the reform of the Council, and only by attacking the strongest cases will the Fellows be able to break through the compact body of obstructives.

TESTIMONIAL TO MR. SHIRLEY MURPHY.

It is with great pleasure we find that it has been decided to raise a testimonial to Mr. Shirley F. Murphy, late medical officer of health of St. Pancras. This gentleman has been compelled, out of self-respect and in the interest of the public, and particularly that portion of it most dependent on the conscientious and judicious discharge of duty by the sanitary authorities, to resign his office. Mr. Murphy has, during a period of nearly seven years, displayed a self-sacrificing devotion in prosecuting with unusual zeal very difficult problems of sanitary reform, and always with unvaried success. His investigations into the epidemic of typhoid fever in St. Pancras were carried out with rare acumen and scientific precision; and it is not too much to say that probably some, at least, of those members of the vestry who have earned an unenviable notoriety for obstructing his researches owe their continued existence to his disinterested services. There can be no doubt that the widespread feeling of sympathy for Mr. Murphy that has burst forth in so many quarters will do much to prevent a recurrence of what may justly be termed a grave social evil, and will serve to accentuate the wisdom of the saying, "out of evil good shall come." It is not enough, however, to affirm a principle in order to secure its adoption and practice; and for this reason we heartily join in the hope that the intended testimonial may meet with ready and substantial support from the public and the medical profession. The object is a worthy one, and deserving of recognition and support. Mr. Murphy's resignation represents a cause that should not be allowed to fail at the instigation and action of those who prefer personal advancement to the national weal. Subscriptions may be sent to the treasurer; the secretaries, Mr. J. W. Gandar, 157, Camden-road, and Mr. J. A. Heaton, 8, St. Bartholomew's-road, N.; or any member of the executive committee, which is at present constituted as follows:—His Honor Judge Chalmers, Hon. Sec., London Fever Hospital; the Hon. Lady Henry Somerset, 16, Albert Mansions, S.W.; Dr. J. G. Glover, 33, Compton-terrace, Highbury, N.; Rev. Mark Wilks, 12, St. Bartholomew's-road, N.; J. H. Badcock, Esq., M.R.C.S., 126, Gower-street, W.C.; John Hamer, Esq., Hon. Sec., Mansion House Council on Dwellings of the Poor.

PARASITES OF THE DOG.

As the seasons come round various ideas as well as things crop up, and of late we have had a plentiful supply of parasitic scares. Last year we had the entozoa of the mackerel wherewith to frighten poor and uninstructed people. Not long before that we were warned of the danger of eating pike and other fish, it having been alleged that trichinæ were found in a jack caught in the harbour at Ostend. This year the scare concerns the dog; and since a F.R.S. lends his name to the movement, let us see what he states. As an anatomist dealing with the vertebrata Mr. Mivart's reputation stands high, but we are not aware that he has made a single experiment or contributed a solitary new fact in relation to the parasites of the dog. He tells us that the "eggs" of the Tænia cœnurus "pass into the sheep's blood." That is ridiculous. The eggs do not pass; but their contents, in the form of six-hooked embryos, having been liberated in the true or fourth stomach, bore their way into the organs of circulation, and are at length carried to the brain. This was experimentally proved by Küchenmeister. Mr. Mivart next tells us that the hydatid, or "bladder-worm stage of existence" of the Tænia echinococcus "is passed, *not in the body of any domestic animal*, but in that of man himself." The italics are ours. This is too bad. One would think Mr. Mivart had never dissected a pig, a sheep, or an ox, in which animals these hydatids are remarkably prevalent, much more so certainly than they are in man. There is not a veterinary surgeon of experience living who has not encountered them. No doubt in Iceland, Australia, and India they are more abundant than in this country. At the Health Exhibition last year Dr. Cobbold showed drawings illustrating the pathological changes produced in the lungs and liver of English sheep and swine, and perhaps *it may interest* Mr. Mivart's friends to know that one liver of a pig there drawn displayed several hundred of the bladder-worms which, he says, do "not live in the body of any domestic animal." They will also be further interested to learn that "six pigs of the same litter, four months old, were similarly affected, all of them having been sent to market and sold as food." In the shilling pamphlet on the Parasites of Meats, "issued by authority," and published by Messrs. Clowes and Sons, the whole subject in relation to infection is fully explained. Another kind of evidence will perhaps better show the misleading nature of Mr. Mivart's dictum. We allude to the evidence to be derived from statistics. By a report received from the executive commissariat officer at Mooltan, it appears that so far back as 1868, during a period of fifteen months, commencing in October, 2109 animals were slaughtered in the district for the purpose of supplying rations to our troops. Of these cattle no less than 899 were affected with hydatids—that is to say, with those bladder-worms which Mr. Mivart has the temerity to inform the public do not pass this stage of their existence in the body of any domestic animal! Sanitarians are greatly indebted to Dr. Cleghorn for publishing these statistics; and, now that we are on the subject, it may be added that the majority of the animals were affected in both liver and lungs. The cysts occupied the liver in 829 instances, and the lungs in 726 instances. The kidneys and spleen were infested in a few cases. In regard to the questionable practice of fondling pet dogs and allowing them to lick the hands and face, we are inclined to agree generally with Mr. Mivart. The act of licking, however, would not be likely to communicate tapeworm, as the readers of the letter in question might be led to suppose, but such action would in certain cases readily convey the germs or eggs of a totally distinct kind of entozoon, which the late Professor Frerichs showed to be very common in the human liver in Germany. *We allude to the Pentastoma tænioides*, better known in its larval stage as P. denticulatum. It is a comparatively harmless entozoon, but, as Dr. Landor has shown (*Berliner Klin. Wochenschrift*, 1878), it may prove *fatal to man in the adult condition*. It has also been known to prove destructive to the dog itself.

INDUSTRIAL INSURANCE.

The abuse of what is known as industrial insurance, especially of infantile insurance, is effectively dealt with in a supplement to a Lecture on Life Assurance recently issued by Mr. Arthur J. Cook. The subject is one the importance of which can scarcely be insisted upon too often or too strongly, in order to secure the further legislative action which the recent notorious cases at Liverpool show to be imperatively necessary. The reckless competition among agents of rival companies and the manner of their remuneration have led to gambling in life policies, which obviously affords inducement and facility for the crimes brought home to the women Flannigan and Higgins. Mr. Cook, from knowledge personally acquired in many parts of the country, is assured "that tens of thousands of husbands have been insured by their wives for sums up to the limit for which a medical examination is not required." The proposal forms for membership of Industrial Companies and Burial Clubs contain certain questions which ought to be answered, and signed by the person whose life is to be insured. There is every reason to believe, however, that in a large proportion of cases the supposed signatures or marks of the husbands upon the proposal forms are those of the wives, when they have not been written by the agents themselves. However this may be, there is no disputing the fact that insuring lives without the knowledge of the insured is one cause of the recent great extension of industrial insurance business.

The system of industrial insurance, and the way it is worked by competing and often unscrupulous agents, calls for a Government inquiry, with a view to further legislation for the protection of the public. Although insurances made by persons having no interest in the life insured are null and void, it is evident that this enactment should be supplemented, as Mr. Cook suggests, by making the effecting of an insurance by an uninterested person a legal offence. The present competitive traffic in small policies constitutes a grave social danger, profitable as it unfortunately is to industrial companies and agents.

THE DIRECTOR OF PUBLIC PROSECUTIONS.

A DRAFT report has just been issued of *regulations under* the Prosecution of Offences Acts, 1879 and 1884. This is to be submitted to the Lord Chancellor and the Secretary of State for the Home Department for their approval. The codification of the regulations drawn up for the guidance of the Public Prosecutor will do much to remove the uncertainty that has hitherto prevailed with regard to that official's duties. We have several times had to call attention to the unsatisfactory way in which criminal investigations have been instituted and conducted, notably in the case of Messrs. Bower and Keates. It is to be hoped that the reforms now under consideration will entirely remove the opprobrium that has undeniably been thrown upon a very important judicial institution. The first clause of the draft regulations defines the cases in which it shall be the duty of the Director of Public Prosecutions to "institute, undertake, or carry on a criminal proceeding in respect of an offence. These are: (1) where the offence is punishable with death; (2) where the offence is of a class the prosecution of which has been undertaken by the Solicitor of the Treasury; (3) where an order is given to the Director by the Secretary of State or the Attorney-General; and (4) where it appears to the Director that the offence, or the circumstances of its commission, is or are of such a character that a prosecution in respect thereof is required in the public interest, and that owing to the importance or difficulty of the case, or to other circumstances, the action of the Director of Public Prosecutions is necessary to secure the due prosecution of the offender." It will be seen that, whilst the conditions under which the Public Prosecutor is to act are more or less closely defined, a very wide discretionary power will still be vested in him. The tenth and last clause, though a short one, will be received by the public and the profession with unqualified approval, seeing that it contains a guarantee against frivolous and vexatious actions, and neglect or misconstruction on the part of the Public Prosecutor. It runs as follows: "The action of the Director of Public Prosecutions shall in all matters, including the selection and instruction of counsel, be subject to the directions of the Attorney-General." So that in cases of difficulty or doubt the opinion and advice of the latter official can be sought, and he it is who will be to a great extent responsible for the proper carrying out of the regulations. Even where the interference of the Attorney-General is not required, the knowledge of the fact that the Public Prosecutor is subject to his directions and answerable to him for any action he may have taken on his own authority will serve as a wholesome check against irregular procedure. The second clause gives to the Public Prosecutor the power of directing investigations which in his opinion are necessary to secure the due prosecution of the offender. The third clause enables the Public Prosecutor, either on application or on his own initiative, to give such advice and assistance as he may deem requisite to clerks of justices of the peace, and to chief officers of police, &c. The fourth clause enacts that where a case has been reserved for the opinion of the High Court of Justice, and counsel has not been instructed for the prosecution, the Public Prosecutor *shall, at his discretion, or on the fiat* of the Attorney-General, issue such instruction. Clause 5 refers to the powers of the Public Prosecutor, as to authorising "the preparation of scientific evidence, the remuneration of scientific witnesses, the payment of extra fees to counsel, the preparation of plans and models, &c.," on the sanction of the Attorney-General. Clause 6 confers upon the Public Prosecutor the power to cause the chief officers of every police district to furnish him with such information as is required by the Prosecution of Offences Act, 1870 and 1884. Clause 7 relates to the production of documents and other things. Clause 8 provides the Public Prosecutor with the power of obtaining documents, &c., from clerks of justices of the peace, whenever he finds that actions or prosecutions which should have proceeded have been allowed to drop. Clause 9 bears on the employment and payment of solicitors engaged by the Director of Public Prosecutions. From a perusal of these proposed regulations, it will be found that an earnest endeavour has been made to put the appointment of Public Prosecutor on a creditable and well-defined basis, and to furnish the country with a judicial department worthy the name. It remains to be seen how far these principles will be exemplified in practice.

MULTIPLE XANTHOMA.

WE have been favoured by Dr. Hardaway with a reprint from the *St. Louis Courier of Medicine* of an account of an interesting case, in a man aged forty-four years, of multiple xanthoma, exhibiting the plane, tubercular, and tuberose varieties of the eruption. The lesions were perfectly symmetrical, except for a remarkable corymbose band on the right side of the trunk in the trajectory of some cutaneous nerves. Such an occurrence has been, hitherto, unrecorded, and was, possibly, determined by a zona. The eyelids, upper lip, chin, elbows, wrists, hands, nates, thighs, legs, feet, genitals, mouth, soft palate, and trachea were involved. The patient had an enlarged liver, and had been treated for chronic hepatitis. Jaundice of twelve years' standing had rendered the skin almost black, and the surface was much scratched and scarred from the intense pruritus ever present. The xanthoma had gradually evolved in the course of four years, and seems to have commenced in the gluteal region. There was a trace of sugar, but no albumen, in the urine. Dr. Hardaway suggests that xanthoma is a diathetic affection, and that jaundice, when it occurs, is secondary to an early xanthomatous implication of the liver.

SHORTCOMINGS OF THE FACTORIES ACT.

WHILE it is not to be expected that the business of factories and workshops will go on without a measure of danger from accident and illness, the last return presented to the Home Office on this subject shows that the minimum of avoidable mishap is still far from being attained. A large percentage of reported cases of accident are evidently due to carelessness on the part of employers and employed. Among these are such as arise from insufficient fencing of machinery, from hurry in piece-work, and from the regrettable practice of entrusting the cleaning of machinery to young boys or girls. A part of the report of special interest to the sanitarian is that which deals with the atmosphere of work-rooms. Interesting facts are communicated with respect to overcrowding, and the varieties of trade phthisis which are apt to follow the inhalation of many kinds of dust-laden air. Of equal or even greater public importance are the statements contained in this return with reference to the condition of the class known as "sweaters," who supply the market, particularly in the clothing trade, with work done in their own homes. Accounts of the destitution prevailing in this class have found their way into the press in many recent publications respecting the state of the London poor. A house-to-house visitation by the Factory Act inspectors during 1884 has further proved the powerlessness of that Act either in controlling working customs or in improving unhealthy domestic surroundings. The Act, indeed, was not meant to extend to the above-named body of operatives. We find, accordingly, that of 1478 such workrooms visited by the inspectors, 734 were exempt from their jurisdiction in all respects, while 367 were equally free from their sanitary control, though subject to that of the local authorities. Those who have visited among the poor, professionally or otherwise, can best appreciate the meaning of these assertions, which not only signify that much unjust overwork continues to press where it can least be borne, but also indicate a serious public danger, for the clothes which are stitched in slums where infectious disease is rife are found a day or two later exposed as the ready-made goods of some fashionable tailor; and the same is true in principle of other kinds of merchandise. There are many who wish to see the Factory Act so amended and extended as to cover the needs of shop *employés*. The returns before us show that the real limit of the influence of that measure is coextensive with paid labour in almost every kind and degree of trade and manufacture, and such an extended application need not, we think, imply a too particular official interference.

COLOUR-BLINDNESS.

AN interesting and important report upon the tests for colour-blindness used in examining candidates for masters' and mates' certificates of competency in the British mercantile marine has just been presented to both Houses of Parliament. It has been drawn up by Mr. Thomas Gray, of the marine department of the Board of Trade, and deserves careful consideration. The colour test in examinations for masters' and mates' competency in the British mercantile marine was established by the Board of Trade in May, 1877; and since then all candidates for these posts have been compelled to pass a test examination as to their ability to distinguish black, white, red, green, yellow, and blue, which are the chief colours that enter into the combination of signals by day or night used at sea. It is singular, however, considering the magnitude of the interests involved, the immense value of the property in jeopardy, to say nothing of the numerous lives that are yearly lost by collisions and by shipwrecks which might well be avoided, supposing them to be, as they unquestionably are, due in many instances to colour-blindness, that these tests have not been generally insisted on, not only for officers, but for men who are on the look-out; yet Mr. Gray states that he has never yet heard that a shipowner, or even a master of a ship, applies the colour test to men employed as A.B.'s. It may reasonably be asked to what end are the mates and captains of merchant ships tested for colour-blindness, when many others to whom the steering and course of the ship is constantly entrusted are never examined at all. In the locomotive service on land, whilst it is absolutely necessary that the engine-driver should have correct appreciation of colours, the signalman might be subject to defect of this sense without harm to the public, since his movements are guided by printed directions in respect of which there can be no mistake, and the coloured glass he turns on to the driver is turned away from himself; but in the case of a ship the movements of each of the steerers are guided by the same sense, and disastrous accidents are sure to happen if either steerer fails to accurately distinguish colour. It would hardly be credited that up to the present time pilots are not compelled to give evidence of their full possession of the colour sense. Mr. Gray points out that for the small sum of one shilling all sailors have an *opportunity of being* examined, and expresses his regret that the Board of Trade has not been supported by the shipowners. That numbers of officers who obtained certificates before the colour test was prescribed are still afloat and in charge of vessels there can be no doubt. These should all be subjected to examination without delay. To the report is attached a page with three cards coloured respectively red, light-green, and black, which are used by the examiners. To this test we should be inclined to take exception, and would suggest the substitution of a pink for the vermilion. It is not uncommon in cases of partial colour-blindness for a patient to indicate saturated colours correctly, whilst he is totally unable to distinguish pink from a light shade of green. It is precisely such colours which are the most important in practice. When the lights are bright and clear red and green, the loom of the vessel can almost always be seen, and no collision can occur but through intense stupidity; but when there is a light haze, a red light becomes pink and indistinct, and the partially colour-blind is then at the greatest disadvantage; the lights may be seen but the vessel is invisible, and the result of confusion of colour may be anticipated. An officer who not long ago was compelled to leave the service on account of colour-blindness had actually brought home several of Her Majesty's vessels as flag lieutenant from the Mediterranean; and in this instance, whilst saturated colours were easily recognised, pale greens and pinks were constantly confused. His defect was easily ascertained by placing coloured lamps at a distance of several hundred yards. Mr. Gray mentions, without recommending, Dr. Thompson's skeins, which are certainly very serviceable. One point in the report strikes us as remarkable. It is stated that in regulations still in force a candidate who fails to pass the colour test may be re-examined after the lapse of three months from the date of his failure; if he fails a second time, he is allowed a third trial at the expiration of three months from the date of his second failure. Does the Board of Trade think colour-blindness a defect that can be got over by study, and that by applying his mind a man can overcome the difficulty as he would the use of the sextant? Surely a competent ophthalmologist should revise the regulations.

AN APOLOGY FOR LONDON SMOKE.

THE debate at the Society of Arts on Wednesday week on the sewage question and on the removal of refuse other than sewage called forth two papers, one by Dr. Thomas Hawksley, the other by Dr. B. W. Richardson. Dr. Hawksley repeated the arguments he has so long and so skilfully used in favour of the earth-closet system, and the total abolition of water carriage of sewage matter. Dr. Richardson dealt almost entirely with the work of the dustman, an official whom all Londoners look upon with almost as much awe as they do on a Prime Minister, and who, indeed, is to many a household even a more important officer, taking him all the year round. There were a number of weighty matters of a practical kind in both essays, but the point which seemed to elicit the most attention, and which met with considerable approbation at the moment when it was announced, was Dr. Richardson's statement that London smoke, bad as it may be and is, is not an unqualified evil in the present state of the sanitation of the metropolis. The argument was that so long as householders are obliged to ventilate their house-drains by means of long tubes extending to or above the roofs of their houses, and so long as they pollute the air in those upper regions, so long also does the fine carbon of the smoke from the chimneys, poured out almost at the same level, exert a salutary influence over the drain emanations. In other words, if London air were entirely free of carbon and were systematically charged from houses with sewer gas, the clear air would become a noxious air, and it is better, therefore, to let the clarification of the heaven above be suspended until the purification of the earth beneath can at the same time be secured. This is, without doubt, a view of the subject in hand that deserves to be considered. That cases of disease have been engendered by the emanations from ventilators into bedrooms seems beyond question, and that carbon in a state of fine subdivision is a destroyer of organic poisons from decomposing materials is not less certain. We ought, therefore, to keep in view in all future sanitation the necessity for cleanliness from the drain of the dwelling as well as from the chimney-pot; sanitation, like all else, having its basis in mother earth.

UNIVERSITY COLLEGE HOSPITAL.

HIS Royal Highness the Prince of Wales has consented to preside at a festival dinner on behalf of the funds of this hospital, to take place on Wednesday, May 13th, at the Langham Hotel. The committee are naturally anxious that the efforts made by the friends and patrons of the hospital and medical school shall prove as successful as the occasion is auspicious. It will doubtless interest the past students at the College and Hospital to know that last year an "Old Students' Jubilee Fund" was initiated by the medical and surgical staff with a view to obtaining means for the ultimate rebuilding of the hospital. The Dean of the Medical Faculty will, no doubt, be happy to receive, in the shape of substantial contributions, appropriate assurances from former students that they are not unmindful of their indebtedness to their *alma mater*.

LORD BRAMWELL ON DRINK.

THERE is nothing so much spoken against nowadays as "drink," and nothing, consequently, in more need of apologists. Some very good judges, indeed, think, from the very severity of the vituperation, that it must be overdone. That vein of charity in the human mind which sees a soul of good in things evil has asserted itself, and both in the medical and legal professions great champions are on the ground to see that justice is done. It is well that it should be so. Lord Bramwell, as the able spokesman of the League for Defending Liberty and Property, has written a smart little defence of "drink." He admits the harm it does: "Disease is brought on, health is ruined, insanity and death are caused, by excessive drink. There is no doubt also that crime is caused by drink." He admits all the harm done, but claims that the good done is more. We must make clear what are Lord Bramwell's views of the good done by "drink." First, "it gives a vast deal of pleasure and enjoyment to those who take it with moderation." But his second, and perhaps chief, argument is that it is useful. With much skill he throws on other shoulders and on another profession the responsibility of stating this part of the case. He falls back on Sir James Paget's well-known argument that the best and the largest quantity of brain-work is being done by the nations in which the use of alcoholic drinks is and has been habitual; and further, that as regards the brain-work of different persons, "they have done the best and most who have habitually and temperately taken alcoholic drinks." It is exceedingly difficult to make comparisons of this kind of much value, as the nations and persons so compared differ in so many other respects besides the mere difference of alcohol-taking. It must be admitted that teetotalism has still its feats to achieve in war, in genius, in statesmanship; and with practical men such rough judgments as that of Sir James Paget will have much weight. But Sir James himself would be ready to admit that even some of those who have done the best brain-work took too much alcohol, and that the world might have got much more good work out of them had they taken less. With one of Lord Bramwell's positions we are not quite satisfied. Society's right to interfere with individual liberty being limited to securing person and property from external and internal attacks, he thinks the prohibition of "drink" not within the right of society. But if its prohibition be not within the right of society, certainly the prohibition of drunkenness is well within its right. Drunkenness is altogether an offence to society, and an injury as well. There is nothing more clear than that drunkenness tends to poverty, and that the family of the drunkard is apt to become a burden on the ratepayers. They have a perfect right to prevent the sale of that amount of drink which involves them in heavy taxation and their fellow-citizens in misery and disease.

EPIDEMIC OF MEASLES AT BUENOS AYRES.

LAST summer Buenos Ayres experienced an epidemic of measles, an account of which is published in the *Revista Argentina* by Dr. Penna. At the beginning of the year there had been a number of cases of very mild enteric fever; these were followed by a considerable increase in fatal puerperal affections, and in June the number of small-pox cases usually existing increased markedly. The first cases of measles which then appeared occurred in lodging-houses, families were then attacked in their residences, and finally the soldiers and gensdarmes of the garrison. The drainage of the city was at the time in an unsatisfactory state. Dr. Penna saw sixty-two cases, varying from two to forty years of age. The incubation period varied from eight to nine days. The symptoms of invasion were, as usual, chills, headache, prostration, languor, anorexia, insomnia, and elevation of temperature, followed by the characteristic oculo-nasal catarrh, photophobia, lacrymation, coryza, sneezing, &c., and afterwards by tracheo-bronchial symptoms, with sometimes violent cough simulating that of croup. Moist and dry râles were heard frequently in the chest, sometimes arousing suspicions of phthisis. Several cases of epistaxis occurred; none of them were severe. In two children considerable subconjunctival hæmorrhage took place, encircling the cornea with a sanguineous ring. There were no cases of convulsions, but delirium was frequent where the temperature was very high. The course of the fever in no instance gave cause for alarm, except where complications existed. The remission on the third day, as described by Jaccoud, and which Kaposi states appears on the second or third, and which by its constancy serves to distinguish the catarrhal inflammation preceding the eruption, was only observed in adults, who could state exactly when the symptoms commenced, and in some doubtful cases which came under observation from the beginning. The temperature remained high for two or three days, sometimes for four, six, or eight days, until the eruption appeared. These latter cases cannot unfortunately be well explained, and sometimes lead to a doubtful diagnosis. Generally the eruption appeared from the fourth to the sixth day, preceded in some cases by a marked rash on the soft palate and pharynx. It invariably commenced on the nose, chin, forehead, and cheeks, never on the trunk or limbs. The eruption consisted of irregular spots, not always of uniform redness, sometimes slightly raised, and occasionally with papules on the edges. The duration of the eruption varied from one and a half to three days. In one child it lasted six days, the colour being very deep. In a girl of three years the eruption appeared and faded at short intervals several times till the third day, from which time it ran its ordinary course. This child had just recovered from a severe attack of broncho-pneumonia. The fever accompanying the eruption frequently rose to 40° or 41° C., especially in children, and the pulse rose and fell with the fever. The complications were capillary bronchitis, which carried off two children, two cases of croup, and two deaths from lobar pneumonia in Indians. In four cases the disease assumed a typhoid character, in two there was tuberculosis, and in some others suspicions of that affection. No active medication was employed, excepting in cases where complications existed.

MR. COMBER ON THE CONGO.

WE have taken frequent occasion to note the good done in the world by medical missionaries. It is very pleasant to see in other and authoritative quarters a similar recognition. At the Geographical Society last week a very just tribute was paid by Sir Henry Rawlinson to the scientific value of the work of Mr. Comber, who is connected with the Baptist Missionary Society, and in that capacity has explored the Congo to a higher point than any previous traveller except Mr. Stanley. He succeeded in getting up 400 miles beyond Stanley Pool, and by his observations giving scientific clearness and definition to the geography of the river and some of its chief affluents. Speaking of the healthiness of the river, he said that on the coast and the delta of the river Europeans seemed to have good health; also on the Upper Congo between Stanley Port and Stanley Falls they did well. Only one had died. But in the Cataract Region of the Congo, between Vivi and Stanley Pool, about 200 Europeans had been located for the last six years, and about 25 per cent. of these had died. Mr. Comber attributed this high mortality to the fatigue and exposure undergone in building, travelling, &c., and anticipates much less sickness when locomotion is facilitated by the railway, and life by the introduction of skilled labour. It is very gratifying to see our missionaries adding to their beneficent work that of observations of the highest scientific and human interest. Much gratitude was expressed by Mr. Comber and others to Mr. Stanley and to the King of the Belgians.

PREVENTION OF THE SPREAD OF SCARLET FEVER.

THE *Medical Record* of New York, March 14th, contains the report of a discussion, in the Practitioners' Society of New York, on the subject of Practical Considerations on the Propagation of Acute Infectious Fevers, especially Scarlet Fever. The first question raised was the contagiousness of scarlet fever during the stage of incubation. Some speakers believed in the possibility of this, but the chief evidence went to show that the disease was very feebly infective at this stage, if so at all. As to measures deemed necessary during the sickness of the patient to prevent the spread of the disease, nothing very new was suggested, and the chief reliance was on isolation and plenty of air, the disinfection of clothes, and the hanging of a sheet wetted with a disinfectant solution before the door. One gentleman thought the room, and not the child, was the chief source of danger. Some speakers were disposed to think that the whole of the desquamative period was not infectious—only the earlier weeks; but Dr. Kinnicall very properly demurred to this, and said that careful thermometric observations showed that a slight elevation of temperature persisted in the third and fourth weeks in a large number of uncomplicated cases. He pointed out, too, that cases had occurred in which desquamation had lasted until the seventy-seventh day. The fourth question discussed was whether physicians should attend both scarlet fever cases and obstetric cases at the same time. Several speakers thought it undesirable. The President thought the risk much exaggerated. We think so oo, if such precautions as those taken with visitors at the London Fever Hospital and by most careful practitioners are duly observed. The chief of these are, after doffing the outer clothing, to put on a surplice over the remaining dress of the physician in going into the patient's room; to wash the hands and, if possible, the mouth carefully on leaving the patient's room, of course prescribing and enforcing all due precautions for limiting the diffusion of the scales from the skin and securing their being burnt. With such precautions as these there will be little risk of the spread of infection by means of the medical attendant.

"AN OFFICIAL FIB."

A MADRID medical journal just to hand thus expresses its views on the subject of the epidemic in the province of Jativa, which was announced in certain newspapers as cholera:—

"What is taking place in Jativa? A malady prevails which has in an unlooked for manner become epidemic, whose symptoms make us suspicious of Asiatic cholera, a disease which has had several victims, which is communicated from one to another, and about the diagnosis of which there is disagreement amongst skilled observers; a disease, too, which has produced much alarm amongst the inhabitants, and has required preventive measures, sanitation, and a hospital service, and, indeed, all the measures which are adopted in dealing with true cholera. In official circles it is called gastro enteritis—an official fib,—which will become incorporated in statistics, reflecting but little credit on the exactitude of science or on the truthfulness of those who write such fraudulent reports. What purpose can be served by this bold attempt to hoodwink public opinion, giving rise to the most dangerous uncertainties, and the result of which it is impossible to foresee? What teaching can efface the occurrences last year in Toledo, Tarragona, Alicante, Novelda, and other places where politicians gave vent to their complaints? The Cortes have now been open three months, and no one has thought it necessary to demand from the Government a satisfactory answer to a question as to their behaviour in this matter, thus leaving the country in a sad state of uncertainty as to the course to be pursued. We shall not be surprised if, as the recent statements from Jativa and another town in Valencia makes us fear will be the case, similar untruths are promulgated on any repetition of these occurrences that may take place this year."

This would seem to be an excellent opportunity for Dr. Ferrán to demonstrate conclusively the practical value of his researches on "cholera vaccinia." His colleague, Dr. Pauli, stated at a banquet, lately given in honour of Ferrán, that he (Pauli) had just come from Jativa. We shall look with interest for an account of what results he has to report.

IMPRISONING AN UNDOUBTED LUNATIC.

NEXT to solemnly hanging a maniac who in his morbid frenzy has slain a fellow-creature, there is no more grotesquely absurd and humiliating proceeding than that of imprisoning a lunatic who declaims somewhat inconveniently in public. We confess our inability to understand how any magistrate with two ideas and time to think can have come to the conclusion that it was consistent with the dignity of a justice of the peace to commit an undoubted victim of insane delusions as is Herbert Freund—sometime an inmate of the City of London Asylum at Stone—for two months imprisonment. The procedure was not fair to Freund, and may be perilous to the community. We have no right, and it is not prudent, to irritate madmen. When this poor man comes out of prison to continue his labours as a prophet acting under "inspiration," he may conceive it to be his duty to do more dangerous work than simply disturbing a crowd or a congregation. Surely this is a matter in which the Secretary of State may be fairly asked to interfere. Freund should either be certified and sent to an asylum or allowed to go at large, and the police should be instructed to move him on gently, though effectually—not to treat him as a man responsible for his actions, which he unquestionably is not.

THE EXPLOSION AT THE ADMIRALTY.

ANOTHER explosion, this time at the Admiralty Offices, Whitehall, took place at about eleven o'clock on the morning of the 23rd. By it the assistant secretary, Mr. Swainson, was injured. The explosive compound, probably dynamite, and about two pounds in quantity, was placed in a cupboard above, somewhat behind and to the left of the secretary, who sustained serious injuries. When found he had evidently been blown from his chair, and was lying against the wall, huddled up, covered with dust, and quite insensible. The unconsciousness lasted for about two hours, and was followed by vomiting. Slight irregularity of the pupils was observed. There were several scalp wounds, one being about three inches in length; all were contused, and there was much dirt in them. The bone was not injured. There was also a contused wound of the left conjunctiva near the inner canthus. There was no deafness. The eyelashes, eyebrows, and hair had been burnt by the explosion.

SIR WILLIAM JENNER.

WE regret to say that Sir William Jenner is at the present time confined to his room by indisposition. About nine years ago Sir William had a short attack of plastic bronchitis, from which, however, he recovered completely. On Tuesday last, after seeing his patients, in the evening there was a recurrence of this affection, attended by slight hæmorrhage. There has been no febrile disturbance, and the malady is gradually, but certainly and steadily, disappearing. Dr. Russell Reynolds has been in constant attendance upon him, and has been in daily consultation with Sir William Gull.

SEPTICÆMIA.

Is septicæmia the result of the action of ptomaines or microbes? This is the question which M. Jeannel and of M. Laulanié have attempted to answer in a brief paper communicated to the French Congress of Surgery (*L'Union Médicale*, April 16th). Ptomaines, being in a state of solution, are able to penetrate the layer of granulations lining a wound. Microbes cannot enter the circulation unless a solution of continuity exists in the layer of granulations. As septicæmia is only observed when a break in the continuity of the living membrane of a wound exists, the authors conclude that the ptomaines play a subsidiary *rôle*, whilst the principal part in the pathogeny of septicæmia is left to the microbes. The arguments used are, in our opinion, not absolutely conclusive.

THE RABBETH MEMORIAL FUND.

THE subscriptions to this fund, which is now closed amounting to between £800 and £900, will be devoted to the maintenance of two cots, one at King's College Hospital, and the other at the Royal Free Hospital. The Senate of the University of London had £100 from the fund placed at its disposal for the founding of a Memorial Medal, but this has been declined with thanks, lest it should be considered a precedent for the authorities of the University. Mr. J. E. Rabbeth (Dr. Rabbeth's father) has offered a sum of money to the Council of King's College to found a Scholarship in memory of his son, who was educated first in the School and then in the medical department of the College. The offer has been gratefully accepted, and, at Mr. Rabbeth's desire, the money will be devoted to a special exhibition for boys passing from the school into the medical department. A final committee meeting will be held at King's College about the middle of May, probably on the 18th.

THE PUBLIC HEALTH (MEMBERS AND OFFICERS) BILL.

A MEDICAL officer of health, in adverting to our recent annotation on the "Public Health (Members and Officers) Bill," considers it very unfair that officers should not be allowed to have shares, or be interested in, waterworks or gasworks. In so far as the prohibition holds good, we are of opinion that it is very undesirable for medical officers of health to be pecuniarily interested in concerns the prospects of which it becomes their duty to promote for the purposes of health. It is only recently that a medical officer of health found himself seriously hampered in his endeavour, during an epidemic of enteric fever, to secure the closure of polluted wells, and the substitution of a water from the public mains, and this because the inhabitants had been given to understand that he was interested as a shareholder in the water company; and it was only as the result of a public announcement that this belief was incorrect that the needed action could be taken. There may be individual cases of hardship, but the principle involved in the prohibition referred to is sound.

THE ARMY MEDICAL STAFF: THE REVISED SCHEDULE.

THE revised schedule of qualifications of candidates desirous of obtaining commissions on the Army Medical Staff, with the conditions of service, has just been issued. The only change which has been made in it since it was withdrawn last month is that the position of the officers on the list will be determined "by the combined results of the competition and qualifying examinations," instead of the competitive examination only. We consider this change to be satisfactory, as holding out an inducement to, and reward for, good work done in the school at Netley.

UNHEALTHY HOUSES.

THE decision arrived at in the case of "Chichester *v.* Lance," which was tried last week before Mr. Justice Wills and a special jury, is another step in favour of tenants who seek to make their landlords responsible for the sanitary state of the houses which have been let to them. In this special case the defendant had effected some so-called improvements, but the work was so carried out as to be ineffectual; and typhoid fever having occurred in the house, the plaintiff has secured judgment and damages to the extent of £40. Landlords will have to understand that when they let premises as dwellings, it must be regarded as an essential part of the transaction that the premises are adapted to healthy occupation.

GUY'S HOSPITAL.

THE governors of Guy's Hospital have, we understand, made a new departure in the mode of election of assistant physicians. Hitherto the vacant posts have been closed to all but Guy's men. There is now a vacancy for an assistant physician at Guy's Hospital, and it is the expressed desire of the governors that applications should be sent in from any gentlemen who may choose to become candidates. This step cannot fail to be regarded with approval by the profession.

At a meeting of delegates from the metropolitan vestries and district boards of works on the 16th inst., resolutions were passed expressing the opinion that it is desirable in the interest of the inhabitants of the metropolis, and as a general principle, that all telephone and telegraph wires within the metropolitan area should be placed underground; that the control of the construction and maintenance of all such wires should vest in and be under the direction of the vestry or district board of the parish or district; and that a letter be sent asking, on behalf of the conference, that the Committee of the House of Commons should hear one witness from each vestry and district board of the metropolis.

From the report made by Messrs. Crookes, Odling, and Tidy, on the composition and quality of daily samples of the water supplied to London for the month ending March 31st, it appears that of the 188 samples examined the whole were found to be perfectly clear, bright, and well-filtered. The mean amount of organic carbon in the Thames-derived waters for March was practically identical with that for February—viz., 0.18 in 100,000 parts of the water. Considering the condition of the river during the month, and the additional care needful to effect good filtration, it is noteworthy that not one of the 188 samples contained so much as a trace of suspended matter.

At a meeting of the Vaccination Officers' Association, held at the Charing-cross Hospital Medical School on Saturday, April 18th, the members considered the best means of securing the vaccination of children born in public institutions, and it was resolved—"That the attention of the Local Government Board be called to the large number of children who are permitted to leave public and parochial institutions unvaccinated, and respectfully suggest that, if a special fee were paid to all medical officers of public and parochial institutions for successful cases of primary vaccition, the returns of vaccination would to a great extent be improved."

Consequent upon the cholera scare in Spain, the Local Boards of Health in many of the Spanish Mediterranean ports and in the Balearic Isles have, it appears, without even receiving orders from Madrid, established quarantine regulations for vessels from the province of Valencia, whilst several towns refuse to receive goods or passengers from the infected districts, which are nearly free from the epidemic. France, Portugal, Turkey, and Holland have already established a quarantine on arrivals from Spain.

The late Dr. Wells' funeral took place at Reading on Saturday, the 18th inst. Some ten thousand persons of all classes of society assembled in the streets and at the cemetery to pay respect to his memory, and a string of carriages more than a mile in length followed his remains. All the medical men in the neighbourhood attended, as well as large numbers of the clergy, the governors of the hospital, and nurses.

A motion by the Croydon Rural Sanitary Authority that the operation of the injunction granted by Mr. Justice Denman on Jan. 12th of the present year, restraining the authority from polluting a piece of water near Garratt, called the Western Pool, by illegally discharging sewage thereinto, might be suspended, was last week dismissed by Mr. Justice Chitty with costs.

Mr. E. Hurry Fenwick, F.R.C.S. Eng., has been appointed Examiner in Elementary Physiology at the Royal College of Surgeons.

On the 4th inst. the death occurred of Dr. James Lawrence Little of New York. He was Professor of Clinical and Operative Surgery in the New York Post-Graduate Medical School and Hospital, Professor of the Principles and Practice of Surgery in the medical department of the University of Vermont, and consulting surgeon to the Mary Fletcher Hospital at Burlington, Vt.

A Bill is before the Legislature of Ontario, and bids fair to become law, which provides that the bodies of persons found dead, also of those who die in public institutions (lunatic asylums excepted), and are not claimed by friends who are willing to pay the funeral expenses, shall be handed over to the medical schools for anatomical purposes.

A Civil List pension of £100 per annum has been awarded to Edward Scott Docker, Deputy Inspector-General of Hospitals, in recognition of his discovery of the uses of ipecacuanha in the treatment of dysentery, and of his services towards Her Majesty's forces.

A deputation of the Parliamentary Committee of the Medico-Psychological Association waited on the chief secretary of the Lord Chancellor, at the House of Lords, on Monday, the 21st, to express their views on the proposed Lunacy Law Amendment Bill.

The Senate of the University of Glasgow, at their meeting on Thursday, the 16th inst., resolved to confer the degree of LL.D. on Professor Struthers of Aberdeen.

We regret to record the death, on the 18th inst., from enteric fever, of Surgeon Paul Bennett Conolly, who was attached to the right camp, Dongola, as surgeon of the Light Division, Camel Corps. He was in his thirty-first year.

The Bill to amend the Medical Act, 1858, has been just issued.

INDIAN HEALTH STATISTICS.

No. II.

The gaol population in 1883 shows, like the army, a marked improvement in health. The average number of prisoners was 88,174, among whom the admissions into hospital were 996, the deaths 31·37 per 1000, and the daily sick 36·5 per 1000. Intermittent fever was the most prevalent disease, and was the cause of more than one-third of the admissions; abscess and ulcer were next in frequency; dysentery and diarrhœa gave rise to the greatest number of deaths, amounting indeed to one-third of the whole; respiratory diseases were the cause of upwards of one-sixth; fevers and cholera rank next; the deaths from dysentery and diarrhœa were 10·64, from respiratory diseases 5·30, from fevers 2·52, and from cholera 2·28 per 1000. The prisoners, like the native troops, show very little susceptibility to enteric fever, only 15 cases with 8 deaths having been reported. The admissions ranged widely in the different gaols. In Bengal they averaged 949 per 1000; in Bombay, 734; in Madras, 861; in British Burmah, 1159; and in the Andamans and Nicobars, 1454. In Bengal some of the gaols yielded a very high death-rate: at Jalpaiguri, of 117 prisoners 35 died, being in the ratio of 299 per 1000; 19 of the deaths were from cholera, and 10 from dysentery and diarrhœa. Gorakhpur, with 607 prisoners, had a death-rate of 146 per 1000, chiefly from the same diseases; Ranchee, with 160, lost 187 per 1000; Dinágepore, with 184, lost 183 per 1000; and Raipur, with 788, lost 143 per 1000. In no less than ten gaols in this Presidency, including those just mentioned, *the mortality was above 10 per cent.* In Bombay, the only large gaol in which so high a rate occurred was at Shikárpur, where of 656 prisoners 66 died. In Madras the highest rate was 86 per 1000 among 93 prisoners in the Tanjore gaol. At Akyab and Kyaukpyu, in Burmah, the mortality in the gaols was as high as 133 and 169 per 1000; at the former from cholera and dysentery, and at the latter from cholera. In the convict establishment at the Andamans, although the admissions and mean sick were much above the average of the gaols in India, the death-rate was comparatively low, amounting to only 19·63 per 1,000; the sickness and mortality and mean sick were all very much lower than in any year on record.

The sanitary sheets received from the gaols, while recording a considerable amount of improvement, show clearly that there is still much to be done in preventing overcrowding, increasing the means of ventilation, improving drainage, water-supply, food and clothing. We trust that the steady work which has been going on of late years in the removal of insanitary conditions may be continued, as the result cannot fail to be well marked in a progressive diminution of the sickness and mortality among the prisoners.

The registration of births and deaths in the civil population of India is still so imperfect that we fear no reliance can be placed on the results. The returns, however, of the mortality by certain diseases, as cholera and small-pox, afford some interesting information when compared with the results for previous years. Cholera prevailed with great severity in the province of Berar, 27,897 deaths having been recorded in a population of a little over two millions and a half; the death-rate by it amounted to 10·61 per 1000. The disease began in April, but it was not till July that it assumed the proportions of a great epidemic; in July and August 25,198 deaths were recorded. In Assam it caused a mortality of 3·29 per 1000, the most fatal months being January and April to July inclusive. In the Bombay Presidency the death-rate from cholera was 2·31 per 1000, being considerably above the average, but its great prevalence and mortality took place in the Northern Deccan Division, 30,298 deaths having been recorded in it out of a total of 37,954 throughout the Presidency. There is a curious fact mentioned in connexion with the question of fairs as one of the supposed causes of the spread of cholera. In the Sholapur district, where it was prevalent, a fair was held in July, and "the disease appeared among the people with great severity"; while in the Kaira district, where it also prevailed, although to a less extent, the usual fair was held in September, and there the disease did not break out.

In the Report a number of examples are given in which the beneficial influence of removal from the place where the disease broke out was very marked. Among the European troops at Allahabad, the native troops at Kamptee, and the prisoners at Jalpaiguri, the disease seemed to be at once arrested by the movement into camp, and in only one instance—that of the prisoners in Gorakhpur gaol—did it continue to prevail after the change of locality. There is one statement in the report in connexion with the spread of cholera which appears to us to be at variance with the facts as shown by the returns. "No case is adduced which favours the idea that the disease was spread by contagion. The positive information regarding the experience of those who came in contact with the sick is, as usual, altogether opposed to this idea. The results are shown in the following statement, which has been so frequently made in previous reports, that attendance on cholera cases involves no danger greater than that to which all persons residing within a cholera-affected locality, and exposed to the causes which induce cholera, are subject." The table shows the proportion of attendants on cholera patients attacked by the disease to have been: among the European troops 1·57, native troops 2·22, and in the gaols 2·51 per cent. But if the statistics be taken of those stations and gaols only at which cases occurred during the year, the ratio among the troops and prisoners will be found to have been: for European troops 0·50, native troops 0·68, and prisoners 1·70 per cent.; so that the proportion attacked of the attendants was considerably above the average of the others. This does not necessarily prove the disease to be contagious, but it shows at least that the attendants are exposed to conditions which render them more liable to an attack. Small-pox prevailed to a great extent among the civil population in 1883, the recorded deaths having amounted to 22,223, or nearly three times as many as in the preceding year. Its greatest mortality occurred in the North-West Provinces and Oudh, where the death-rate was 3·14 per 1000. In Assam and Berar and in the Madras Presidency it was considerably above the average of past years. Vaccination continues to receive much attention in India, but is still very far from being general.

A brief summary is given at the end of the Report of the investigations made at Calcutta by the German Commission, consisting of Drs. Koch, Gaffky, and Fischer, and by the British Commissioners, Drs. Klein and Heneage Gibbes; but it is unnecessary to notice this, as the information contained in it is rendered of comparatively little value by the more extended reports which have since been published by the Commissioners themselves. In the appendix is a detailed medical history by Surgeon-Major Johnson of the Aka Expeditionary Field Force; and also a medical report of the Indian Division, Egypt Expeditionary Force, 1882, by Deputy Surgeon-General Colvin Smith, who accompanied it as Principal Medical Officer. The latter shows the force sent from India to Egypt to have consisted of 199 officers, 1713 European and 3961 native soldiers, and 6478 followers. The period from the date of arrival of each corps till it was struck off the force varied from thirty-four to sixty-three days. The admissions into hospital from the European troops amounted to 361 and the deaths to 9, and from the native troops to 485 and 6. These numbers, calculated on the strength in the usual manner, show the *annual* ratio of admissions to have been: of the Europeans 1597 and of the natives 919 per 1000, and the deaths to have been 39·82 and 11·36 in each class respectively. Of the 9 deaths among the European troops 3 were from gunshot wounds, 2 by drowning, 3 by sunstroke, and 1 by diarrhœa; of the 6 among the natives, 4 were by gunshot wounds, 1 by dysentery, and 1 by gangrene of foot following an accident on shipboard. The 3 deaths by sunstroke occurred in the Seaforth Highlanders, and were, we regret to say, a result of drinking at Suez and subsequent exposure to the sun; 10 cases occurred in the short march of three miles from Suez to the Victoria Hospital. There were 14 cases in the force during its service in Egypt, and all of them in this regiment. The most prevalent diseases among the Europeans were conjunctivitis and ague, and among the native troops dysentery, conjunctivitis, and ague; dysentery was the cause of one-fourth of the admissions among the latter. Considering the short period during which the Indian contingent was in Egypt and the arrangements which had been made for its reception, it must be obvious that no fair comparison could be instituted between the sickness and mortality in it and the rest of the force in Egypt. But the circumstances under which the Eastern Soudan expedition was undertaken so much more nearly resembled those under which the Indian force served as to permit of such a comparison. That campaign lasted fifty-one days, and was undertaken after due arrangements had been made.[1] The admissions into hospital were in the *annual* ratio of 912, and the deaths of 224·4 per 1000, all of them in action. The sickness, therefore, was almost identical with that of the Native Indian Contingent in Egypt; no deaths were caused by disease in the one force and only two in the other, and of the latter one was consequent upon an accident.

The history of the Aka Expedition by Surgeon-Major Johnson is very interesting. It consisted of 30 officers, 1028 men, and 1993 followers, and lasted two months. None of the officers died; four of the men were killed, and one died of pneumonia, and there were sixteen deaths of followers—ten from pneumonia and bronchitis, four from fever, and two from diarrhœa. Three of the deaths in action were caused by poisoned arrows, and an interesting account of the symptoms is given in the report: The poison is believed to be prepared from the root of the *aconitum ferox*. Great difficulty was experienced in some places in effecting the carriage of the sick in dandies, and some *thappas* were constructed, which are stated to be admirably adapted for the purpose over difficult ground. They are made of canes and split bamboos, and are carried on the back and shoulders of a coolie, and supported by a flat band of woven cane or bamboo, one end supporting the *thappa* below the seat and the other passing round the head and across the forehead of the carrier. "A strong coolie will in this way carry a man of ordinary weight up or down the steepest pathway, as both his hands and arms are free to assist him in difficult places." This appears closely to resemble the modification of the Tyrolean kraxe proposed by Staff-Surgeon Michaelis of the Austrian Army for the carriage of sick and wounded in mountainous districts, to which we called attention in THE LANCET of January 3rd last. We again recommend these proposed means of transport to the consideration of the military medical authorities.

---

[1] THE LANCET, Sept. 6th, 1884.

BRITISH DENTAL ASSOCIATION: MIDLAND BRANCH.

THE annual meeting of the Midland Branch of the British Dental Association was held on Friday the 17th inst., at the University College, Nottingham. Mr. H. Blandy presided. A number of specimens, appliances, &c., were shown, and several demonstrations given. The principal of these were—an operation performed illustrating Herbet's method of gold filling; a new method of vulcanite plates in steatite by the dry system, was shown by Mr. Brunton of Leeds; and demonstrations of taking models in plaster by Mr. W. Bowman Macleod.

A Council meeting was subsequently held, the retiring President (Mr. J. Harrison, Sheffield) in the chair. The report stated that in December last the Central Branch was inaugurated in Birmingham, and the Council rejoiced in this multiplication of centres, from which the influence of the British Dental Association must radiate. The membership of the Association was eighty-eight, which was far below what they desired to see. The Council nominated Mr. H. Blandy, of Nottingham, as President, and Mr. A. M. Mathews, of Bradford, President-elect; it is also recommended the holding of the next annual meeting at Bradford. The report was adopted.

In his address, the PRESIDENT (Mr. H. Blandy), after briefly sketching the history of the British Dental Association, alluded to the work of their venerable friend, Mr. John Tomes, whose name would be known over the whole scientific world for his valuable work as an anatomical and physiological investigator, and revered by his brother dentists as the champion and pioneer of dental reform. They sought to make the dentist an educated and scientific man, and they would have him pass an examination in arts identical with that formerly demanded of the student of medicine alone. They required an apprenticeship of three years to a registered and qualified practitioner, and a three years' course of hospital study in medicine and surgery, as well as courses on special dental subjects in a dental hospital. This was at last granted by the College of Surgeons, and a curriculum of study marked out. In 1878 they obtained the Dentists Act, which demanded registration of all persons practising dentistry. Another great evil of the dentistry of the past was the advertisements of the quacks. The College of Surgeons demanded of their licentiates a solemn undertaking that they would not advertise or associate their names with anyone who did. It was to be regretted that dental advertisements and show-cases still appeared to disgrace their profession. The objects of the British Dental Association included not only the study of dental and the allied sciences, the maintenance of the honour and interests of the profession, and the publication of a periodical journal, but the upholding of the spirit and provisions of the Dentists Act. It seemed to him that one great difficulty of the administration of that Act lay in the constitution of the General Medical Council, which had the supervision of registration and was the chief authority. It would not do for them to advocate the abolition of the House of Lords; but it was certainly open to grave consideration whether it would not be to their advantage if it were more representative—i.e., if taxation and representation were more proportionate. They had those amongst them who were earnest workers in the field of science. It was known that bacilli and micrococci had been found in the mouth and in the tissue of decayed teeth, as also in the alveolar abscesses; and when it was recognised how rapidly they multiplied, it would be seen how important a bearing they had on dental diseases. It had been held that the human race was deteriorating in physical, if not in mental power. Models were constantly exhibited which proved that jaws were becoming more and more contracted; that wisdom, bicuspid, and lateral teeth were often absent; and that even the teeth which were present were not nearly so good as they used to be. The President concluded by welcoming the members to Nottingham.

Dr. SMITH moved a vote of thanks to the President, which Mr. STORY (Hull) seconded. The motion was carried.

In the afternoon Mr. Marshall read a paper on "Nutrition in Early Life"; Mr. F. Harrison a paper on "The Preparation of Tissues for Microscopical Examination"; and Mr. L. Matheson one on "Artificial Separation of Teeth."

This concluded the meeting, and in the evening the members dined together at the George Hotel.

MAHOMED MEMORIAL FUND.

A MEETING of the subscribers to this fund was held in the Governors' Court Room, Guy's Hospital, on Thursday, April 16th. Dr. S. Wilks, F.R.S., took the chair, and explained the steps which the subcommittee had followed to carry out the resolutions of the meeting held at Guy's Hospital in December last. Mr. Durham, the treasurer to the fund, stated that the amount subscribed slightly exceeded £2500, of which sum all had been received except about £295. It was then proposed by Mr. Durham, seconded by Dr. F. Taylor, and carried unanimously, "That the fund subscribed be entrusted to three gentlemen, to be hereinafter elected, who shall have full and absolute power to invest, hold, and dispose of the money placed in their hands, both as regards capital and the interest that shall accrue upon it, at their discretion, in such way as may seem in their judgment best calculated to promote the interests of those left by Dr. Mahomed and to fulfil the objects for which the fund has been subscribed, subject to the following conditions:—(1) "That during the lifetime of Mrs. Mahomed, and while she remains unmarried, the interest upon the fund shall be regularly paid to her for her use; (2) that, if at any time it may seem good to them, the trustees may dispose of portions of the capital for the immediate use or benefit of Mrs. Mahomed or any one of the children, provided always that no larger sum than one-quarter of the capital be given to Mrs. Mahomed for her own use, nor any larger sum than one-fifth or three-quarters of the capital sum be expended upon any one of the five children, except in case of the death of any one or more of the children, under which circumstances a proportionately larger share may be appropriated to any one or more of the survivors."

Mr. Eastes proposed, Mr. Aiken seconded, and it was unanimously resolved, "That in accordance with the foregoing resolution, Dr. Cayley, Dr. Goodhart, and Mr. Field be requested to take charge and dispose of the money subscribed; and, in the event of the death or resignation of any one of these gentlemen. the remaining two shall appoint a new trustee." It was proposed by Mr. Lushington, and carried, "That the report of this meeting, and the resolutions adopted, be forwarded to the medical journals and also to each of the subscribers to the fund, with a complete list of the subscriptions." Votes of thanks to the subcommittee, to the treasurer of the hospital, and to the chairman of the meeting, brought the proceedings to a close.

The following additional subscriptions have been received:

	£	s.	d.		£	s.	d.
W. A. Alkin, Esq.	1	1	0	T. A. Ives-Howell, Esq.	3	3	0
R. W. Brogden, Esq. ...	2	2	0	Hugh R. Ker, Esq.	1	1	0
Percy H. Garner, Esq. ...	1	1	0	J. V. Salvage, Esq.	1	1	0
T. S. Howell, Esq.	5	5	0				

The Treasurer and Secretaries wish to express their cordial appreciation of the courtesy and kindness that have been shown by the Editor of THE LANCET in inserting notices relative to the fund, and in thereby much promoting its success.

ARTHUR E. DURHAM, Treasurer.
JAMES F. GOODHART, } Secretaries.
W. H. A. JACOBSON, }

SOUTH LONDON SCHOOL OF PHARMACY.—The following prizes were presented to the successful competitors at the school examinations (held from April 7th to 11th) on Wednesday last:—Senior Chemistry: David Kingan, medal; John G. Rowell, certificate. Junior Chemistry: Thomas C. Barkas, medal; Ernest A. Long, certificate. Botany: David Kingan, medal; Ernest Daintree, certificate. Materia Medica: Ernest Daintree, medal; Thomas C. Barkas, certificate. Pharmacy and Practical Dispensing: Ernest A. Long, medal; Jeremiah Burgess, certificate. Extra Certificates of Merit: Messrs. Carr, Fulcher, Moore, Pyle, Reedman, Robinson, and Tirrell.

WILLS OF MEDICAL MEN.

THE will of Mr. John Charles Parrott, late of Clapham-ommon, surgeon, who died on January 31st last, was proved n the 4th ult. by Mrs. Maria Parrott, the widow and sole xecutrix, the value of the personal estate amounting to pwards of £62,000. The testator bequeaths his household urniture and effects to his wife; £10,000 each to his son lfred Albert and his daughter Julia Isabel; £10,000 upon rust for his daughter Mrs. Annie Walter; £5000 to his son ohn Charles; and some other legacies. His freehold esidence, and the residue of his shares, bonds, insurance oney, and cash at his bankers, are to be held upon trust r his wife for life, and then for his two daughters and his on Alfred Albert.

The will and codicil of Thomas Derry Jones, M.D., late of , Loraine-place, Holloway, and 328, Upper-street, Islington, ho died on January 21st last, were proved on the 20th ult. y Ralph John Dent, J.P., and John Chalmers, M.D., the xecutors, the value of the personal estate amounting to ver £12,000. The testator bequeaths legacies to his xecutors, coachman, and others; £1000 each to Ada and ane Kipling, and £500 to Bessie Mitchell, the payment f these three latter legacies being postponed until the death f his mother. Subject to the foregoing bequests, the estator leaves all his property to his mother.

The will and codicil of Mr. William Coulthard, surgeon, ormerly of 42, Hertford-street, Mayfair, but late of 49, ueen's-gardens, Hyde-park, who died on January 27th last, ave been proved by Henry White and John Coulthard, the xecutors, the value of the personal estate amounting to ver £8500. The testator leaves £100 per annum for the enefit of his sister Mrs. Clara Ann Farmer; £100 to each of is executors; and the residue of his real and personal state to his three half-sisters, Phœbe, Jane, and Frances oulthard.

The will of John Collis Browne, M.D., late of Mount lbion House, Ramsgate, and of 11, Sandringham-gardens, aling, who died on August 30th last, has been proved by Mrs. Harriet Browne, the widow and sole executrix, the alue of the personal estate amounting to over £4700. The estator gives all his real and personal estate to his wife bsolutely.

The will of Mr. Forster Fowler Martin Maynard, physician nd surgeon, late of Kemendine House, Baldslow-road, Hastings, who died on January 1st last, was proved on the th ult. by Mrs. Charlotte Harriett Maynard the widow, Mr. Edward Garnet Man and Mr. Lionel Booth, the executors, he value of the personal estate exceeding £800. The estator gives his household furniture and effects to his wife, and confirms the assignment to her of his life ssurance policy; and complimentary legacies to Mr. Man and Mr. Booth. The residue of his real and personal estate s to be held upon trust for his wife, so long as she shall live without marrying again, and then to be equally divided etween his children.

The will of George Ridsdale, M.D., late of 26, Endsleigh-gardens, Euston-road, who died on November 11th last, was proved on the 20th ult. by Mr. Alexander Greaves, the acting executor. The testator leaves all his real and personal estate upon trust, the income to to paid to his wife for life, and then to his god-daughter, Ethel Fanny Graves.

The will of William MacOubrey, M.D., barrister-at-law, formerly of 50, Charlotte-street, Fitzroy-square, but late of Oulton, Suffolk, who died on August 24th last, was proved on the 13th ult. by Mrs. Henrietta Mary MacOubrey, the widow and sole executrix, to whom he leaves, devises, and bequeaths all his real and personal estate, to be at her own disposal.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Nathaniel James Powell, of Devonshire House, Beckenham, £250 to the Royal Hospital for Incurables, Putney; and £100 each to the London Hospital, Whitechapel-road, the London Hospital, Victoria-park, and the Eastern Dispensary, Leman-street.—Miss Sarah Ward, formerly of Leicester-place, Camberwell New-road, but late of Carshalton-grove, Sutton, £500 New Three per Cents. each to the Brompton Hospital for Consumption and Diseases of the Chest, and the Victoria-park Hospital for Consumption and Diseases of the Chest.—Mr. John Christopher Augustus Voelcker, of 39, Argyll-road, Kensington, analytical chemist and Doctor of Philosophy, £100 each to University College Hospital, and the German Hospital, Dalston.—Mr. William Danby Baker, of 385, Kennington-road, on the death of Miss Charlotte Clarke, one-third of £3000 Consols each to the British Home for Incurables, Clapham, and the Royal Hospital for Incurables, Putney.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6195 births and 3966 deaths were registered during the week ending the 18th inst. The annual death-rate in these towns, which had increased in the previous six weeks from 20·6 to 25·0, declined again to 23·2. During last quarter the death-rate in these towns averaged 21·9 per 1000, and was 2·3 below the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 16·2 in Hull, 16·3 in Derby, 17·8 in Nottingham, and 17·9 in Birkenhead. The rates in the other towns ranged upwards to 32·4 in Newcastle-upon-Tyne, 33·9 in Sunderland, 33·3 in Cardiff, 35·7 in Plymouth, and 35·9 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the preceding seven weeks from 377 to 478, further rose last week to 484; they included 190 from measles, 109 from whooping-cough, 46 from small-pox, 42 from "fever" (principally enteric), 38 from scarlet fever, 30 from diphtheria, and 29 from diarrhœa. No death from any of these diseases was recorded last week in Wolverhampton, whereas they caused the highest death-rates in Cardiff, Newcastle-upon-Tyne, and Sunderland. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Cardiff, and Sunderland; from whooping-cough in Preston and Sunderland; and from scarlet fever in Halifax and Sunderland. The 30 deaths from diphtheria in the twenty-eight towns included 21 in London, and 2 in Portsmouth. Small-pox caused 67 deaths in London and its outer ring of suburban districts, 2 in Liverpool, 2 in Manchester, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had risen in the preceding three weeks from 830 to 910, had further increased to 1062 on Saturday last; the admissions also further rose from 179, 141, and 185 in the previous three weeks to 307 last week, the largest number under treatment since June last. The Highgate Small-pox Hospital contained 92 patients on Saturday last, 23 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 448, 478, and 512 in the preceding three weeks, declined again last week to 449, and were 21 below the corrected weekly average. The causes of 101, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Sunderland, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Blackburn, Sheffield, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 25·0 and 23·4 per 1000 in the preceding two weeks, was 23·3 in the week ending the 18th inst. The rates in the Scotch towns last week ranged from 14·8 and 18·3 in Greenock and Perth, to 27·1 in Glasgow, and 29·0 in Paisley. The 569 deaths in the eight towns included 24 from measles, 23 from whooping-cough, 12 from diarrhœa, 7 from "fever," 7 from scarlet fever, 3 from diphtheria, and not one from small-pox; in all, 67 deaths resulted from these principal zymotic diseases, against 84 and 68 in the preceding two weeks. These 76 deaths were equal to an annual rate of 3·1 per 1000, which was 0·3 above the mean rate from the same diseases in the twenty-eight English towns. The 24 deaths from measles corresponded with the number in the previous week, and included 22 in Glasgow. The fatal cases of whooping-cough, which had been 34 and 17 in the preceding two weeks, rose again to 23 last week; 8 occurred in Edinburgh and 6 in Glasgow. The 7 deaths referred to "fever" showed a decline of 3 from the numbers in the previous week and included 3 in Glasgow and 2 in Dundee. Of the 7 fatal cases of scarlet fever 5 occurred in Glasgow and 2 in Paisley; and 2 of the 3 deaths from diphtheria were returned in Dundee. The 12 deaths attributed to diarrhœa included 6 in Glasgow, and were 3 below the number in the corresponding week of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 130 and 134 in the previous two weeks, were 131 last week, and exceeded the number in the corresponding week of last year by 3. The causes of 73, or nearly 13 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 40·4, 33·6 and 33·2 per 1000 in the preceding three weeks, was last week 33·7. During last quarter the death-rate in the city averaged no less than 34·0 per 1000; whereas in London and Edinburgh the rate did not exceed 20·8 and 20·0 respectively. The 228 deaths in Dublin last week showed an increase of 10 upon the number in the previous week, and included 29 which were referred to the principal zymotic diseases, against 32, 24, and 29 in the preceding three weeks; 15 resulted from measles, 8 from "fever" (typhus, enteric, or simple), 3 from scarlet fever, 2 from whooping-cough, 1 from diphtheria, and not one from either small-pox or diarrhœa. These 29 deaths were equal to an annual rate of 4·3 per 1000, the rates from the same diseases not exceeding 3·0 in London and 2·1 in Edinburgh. The fatal cases of measles in Dublin, which had been 13 and 19 in the previous two weeks, declined again to 15 last week. The 8 deaths from "fever," however, showed a marked increase upon recent weekly numbers. The fatal cases of scarlet fever were also more numerous. Five inquest cases and 5 deaths from violence were registered. The 80 deaths in public institutions were more than a third of the total deaths recorded. The deaths of infants showed a further decline, while those of elderly persons exceeded the numbers in the two previous weeks. The causes of 20, or nearly a tenth of the deaths registered, were not certified.

STRANGULATED OMENTAL HERNIA.

To the Editor of THE LANCET.

SIR,—The interesting letters by Mr. Timothy Holmes and Mr. Parker, published in your issue of April 11th, revive once more the question of the due appreciation of strangulated omental hernia. Mr. Parker denies a clinical being to this form of rupture, and contends that, so far as a symptomatic outline is concerned, it is without form and void. In spite of the undoubtedly strong arguments so ably advanced by Mr. Parker, I would still venture to place myself among those who adhere to the ancient surgical faith, and believe that a strangulated epiplocele will be attended with the same symptoms, in a modified form, that follow the strangulation of bowel in a rupture. The disposal of the question must rest at present upon individual experience and impression. It will be answered when Mr. Parker's arguments have been supported or opposed by more extended clinical data, and when they have met fully the test of the post-mortem room. So far, Mr. Parker has clearly demonstrated that a serious fallacy may exist in the diagnosis of strangulated epiploceles, and it would be at present difficult to maintain that this fallacy has not crept into all reputed cases of strangulated omentum with symptoms. The point, however, has rather a negative than a positive value; it shows that certain cases have been wrongly diagnosed, but it still does not dispose of the main question, nor touch the possibility that certain precise symptoms may follow the strangulation of a portion of omentum. It would appear that in the discussion too little notice has been taken of the important part the abdominal nerve centres play in the production of strangulation symptoms. It will, I presume, be allowed that the omentum contains nerves, and that these nerves are derived more or less directly from the great solar plexus. These nerves must obviously be damaged when the omentum is compressed, and as it can be shown that strangulation symptoms may follow upon a like lesion to other offshoots from the great plexus, it will not be unreasonable to expect that strangulation of omentum alone may be attended by the same clinical manifestations. The almost immediate pain, collapse, and vomiting that attend acute volvulus of the sigmoid flexure can hardly depend, in the first instance, upon the mechanical obstruction in the bowel, but are due rather to the impression conveyed to the solar plexus from the damaged nerves in the twisted gut. The earliest symptoms also in Littré's hernia must be explained by a reference to sudden nerve impressions rather than to a mechanical obstruction, since the lumen of the bowel is not entirely occluded, and an immediate paralysis of the ensnared part could hardly meet the manifestations produced. The collapse, deep abdominal pain, and copious vomiting that often attend crush of the testes would appear to depend upon damage to the spermatic plexus—a close derivative from the solar. The same applies to instances where in infants orchitis of an undescended testis has given rise to symptoms hardly to be distinguished from those of strangulation. In several instances, and notably one recorded by Dupuytren, an inflamed hydrocele has been mistaken for a strangulated rupture; and other cases may be mentioned where the leading symptoms of acute obstruction have followed a lesion of a limited part of the peritoneum. In the light of such instances, it may be expected that damage to the peritoneum forming the omentum would not improbably lead to such disturbances as slight shock, abdominal pain, vomiting, and constipation.

An important argument now comes to the front. "I continue," writes Mr. Parker, "unshaken in the firm conviction that strangulation alone, as strangulation, can have no symptoms, seeing that the tightest ligature never produces them." I venture to think that this ingenious argument involves a fallacy. The two forms of constriction alluded to are not identical. Mr. Parker will agree with me that certain lesions are measurable in a surgical sense. There is a lesion which when of light degree may cause severe irritation and widely diffused nerve disturbance, and which when of intenser character may cause more or less abrupt death of parts and lead to none but local manifestations. Many illustrations of this are afforded by surgery. In spontaneous strangulation of omentum the nerves are compressed, but not at once destroyed. They remain, as it were, alive under the keenly constricting band, and become the starting-point for widespread disturbance. In the case of the ligature, the parts enclosed within the thread are practically killed outright, the nerves are crushed, and their conducting power destroyed. The lesion would appear to be, and to remain, purely local. From a neighbouring part a nearly parallel example may be taken. A bunch of internal piles descend, and are nipped by the sphincter. The ensnared part is not killed outright, it may survive for days, and it becomes the seat of intense irritation leading to the most grave disorders. The same phenomena do not appear when the same piles are subjected to the surgical ligature, and I do not think that Mr. Parker would deny that symptoms attend strangulated piles because ligation of those piles is not followed by identical disturbances.

I am, Sir, yours truly,

Golden-square, April 17th, 1885. FREDERICK TREVES.

REFORM AT THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Your leader of this week calling attention to the general meeting of the Association of Members of the College of Surgeons must be very pleasing to Members of the College who already have joined together in large numbers, and are exerting themselves energetically to obtain from the College some sort of recognition. There is only one passage to which I wish to call attention. You say "There is difficulty in carrying out the programme drawn up by the Association, and the burden of showing how these difficulties may be overcome lies with the Association." Now, Sir, in my opinion, when any business firm, or even corporate body, is desirous of contributing to the interests of the public at large, and of removing a grievance known to exist, the public is not called upon to point out to the firm or corporate body how they are to conduct their own affairs in order to remedy the evil complained of. It may as well be argued that a medical man having a long round of visits before him may refuse to attend an urgent message unless and until this patient first points out how the day's work can be satisfactorily gone through. Surely such interference would be laughed at and treated as an act of impertinence. I am of opinion that this applies equally to the College of Surgeons, and that it rests with the Council to consider how to advance the interests of the members when once the latter have made known their grievances and desires.

I am, Sir, your obedient servant,
M. CLIFFORD, M.R.C.S. Eng.
Warrington-gardens, April 22nd, 1885.

The following letter has been addressed to the Honorary Secretaries of the Association of Members of the Royal College of Surgeons of England:—

Dulwich, April 21st, 1885.

DEAR SIRS,—In reply to your invitation to attend a meeting of the Association of Members of the Royal College of Surgeons of England on May 5th, I am afraid that, as I do not approve of the separation of Fellows and Members into hostile camps (for which, I am bound to say, your Association is not wholly responsible), my presence at your meeting would hardly help you, unless indeed you are prepared to take steps for co-operating with the Association of Fellows, in which case I would gladly assist. It appears to me, as I believe it does to others, that the resolutions passed at the meeting held at the College in March, 1884, afford a basis on which Fellows and Members *ought to be* able to work for the common good. Those resolutions asked, *inter alia*, for the following important reforms:—(1) That the Fellows and Members should be invested with a larger share in the management of the College; (2) that no important alteration should be made in the constitution or relations of the College without the consent of the Fellows and Members; (3) that there should be an annual meeting of Fellows and Members, at which the annual report of the Council should be presented, received, and adopted. Had the Fellows and Members, since the meeting unitedly adhered to this moderate programme, there can, I think, be no doubt that the Council would have been ere this forced to yield; but dividing into two Associations, each bent upon securing as much for its own order as possible, the interests of the profession fell an easy prey to those who believe in the ancient maxim, *divide et impera*, and the Council of the College has been able for a whole year to act as if it had never accepted any of these proposals, not even the third, in a modified form, or as if its acceptance of that proposal was one of those inoperative resolutions which Mr. Marshall told us the Council is in the habit of passing. As there may possibly be some both in your own Association and among the Fellows who will agree with me in thinking that our true policy, in view of the determined hostility of the Council and officials of the College to all reform, should be to seek union *rather than* to divide our powers, I shall send a copy of this letter to the medical papers.

I am, dear Sirs, faithfully yours,
H. NELSON HARDY.
The Hon. Secs., Association of Members, Royal Coll. Surg., Eng.

THE CHELTENHAM APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

To the Editor of THE LANCET.

SIR,—As one of the candidates for the above appointment. allow me to thank you for the paragraph in your last issue, In addition to the fact, which you lay stress upon, that Mr. Roch possessed only one qualification at the time of his appointment, there are other objections to the election, which it is well the thirty-four candidates should know.

1. The advertisement required that applications for the office should state age, residence, and *qualifications*. The gentleman elected did *not* state his qualification (M.R.C.S., [illegible]), but merely added to his name Deputy Surgeon-General.

2. The notification to the Local Government Board, instead of being made within seven days, was delayed by the Sanitary Authority (or rather, as it really was, the Mayor and Town Clerk) for three weeks, during which time the gentleman elected obtained, after *special* examination of an [illegible] character only, and for which no curriculum is required, a [illegible] in medicine from a college in Ireland, the value of which, as you rightly say, "can best be judged of by the circumstances under which it is procured."

3. One of the applications for the office was never opened or considered. There can be no doubt that this election was conducted in a slovenly manner. The Public Health Committee and the Town Clerk (to whom a selection of six candidates was delegated) appear never to have considered the qualifications of the several applicants, the Town Clerk ruling that this was only necessary in the case of the elected one, the consequence being that the majority of the Town Council, in voting for Mr. Roch, thought they were supporting a gentleman at least as well qualified as the other five candidates, and his want of legal qualification was *never discovered until after his election*; *further, if one* application was never opened, the inference is that others shared the same fate.

I am *pleased to find that several of the candidates* contemplate taking further action, and I shall be glad to join in any movement for testing the legality of the appointment. The best thing, however, in my opinion, would be—if I might venture to suggest such a course—for the gentleman elected to resign and submit his claims, now that he is fully qualified, for re-election.

I am, Sir, yours faithfully,
A GRADUATE.
April 20th, 1885.

THE MEDICAL BILL AND THE SCOTCH UNIVERSITIES.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to correct a mistake into which I fell in my letter of the 14th inst.? I find on reference to the journals of the House that the Medical Act Amendment Bill was exempted in the first instance from the general massacre of the innocents, and was only withdrawn at a later date, when it became evident that it would be hopeless to attempt to do anything beyond absolutely necessary work in an expiring session. I feel that this explanation is due to Sir William Jenner, whose knowledge of the detail of the question was really greater than mine, but from whose conclusions I still venture to dissent; and whilst thanking you, Sir, for your personal expressions of courtesy, I must, with all respect, continue to express my dissent from the views which you so ably advocate.

I am, Sir, yours faithfully,
R. FARQUHARSON.
Reform Club, April 22nd, 1885.

SMALL-POX AT SALVATION ARMY BARRACKS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of last week a correspondent states that small-pox is now, and has for some time past been, very prevalent among the persons residing in the barracks of the Salvation Army, Clapton, and that scarcely a day has passed without some patient being removed. This is absolutely untrue. Since the barracks have been opened at Clapton, three years ago, there have been in all twelve cases; seven this year, three in 1884, and two in 1883. Every care is taken to prevent infection spreading; on the slightest suspicious symptom the cadet is isolated (in a room kept on purpose for infectious cases), and as soon as small-pox is pronounced the patient is at once removed to the hospital at Highgate. Every precaution as regards disinfection is taken after a case has occurred. So far there has been no spread of the disease in the barracks, the cases being isolated ones. In one case the disease was evidently caught at Plymouth, as symptoms of small-pox appeared within a week of the patient's arrival at Clapton. A matron and a certificated hospital trained nurse have the cadets under their constant supervision, and are prompt in isolating any one showing the slightest suspicious symptom of any infectious disorder; and, *considering* the number of persons residing in the barracks (over 300), and how prevalent small-pox has been in the immediate neighbourhood, in my opinion the army is to be congratulated *that there have not* been more cases. Either the matron, the nurse, or the medical officer, will be very happy to show any qualified medical man over the barracks.

I am, Sir, yours faithfully,
FRED. H. [illegible], M.D.,
Lower Clapton, April 21st, 1885. Med. Off. [illegible] Salvation Army.

WITH THE TROOPS IN THE SOUDAN.

(From our Special Correspondent.)

Base Hospital, Camp near Suakim, March 27th, 1885.

Since yesterday week there have been constant skirmishes with the enemy, but that of Sunday last was by far the most severe, even critical, action that has taken place; for it was one in which the Soudanese made a most determined attack on our zereba and troops, and were not repulsed until they had managed to put some 250 of our men (killed and wounded) *hors de combat*. Conflicting as the reports are which are heard from all quarters as to how this loss was occasioned, the opinion of most of those I have seen and spoken to on the subject, and who were eye-witnesses of, participators in, and also sufferers by the fight, may be summed up in a single word—Surprised! That for a time it was a disaster is certain, and a palpable disaster into the bargain—a second Isandhlwana affair, averted only by the coolness and steady bearing of our English troops. It appears that the forces under the command of General McNeil had started on the morning of Sunday, the 23rd, to form a zereba and establish a position on the line of communications a few miles out for the general advance of the main body of our troops, which intended to move a few days afterwards for Tamai *en route* to Berber. The troops, consisting of the Berkshire Regiment, Marines, Sappers, Sikhs, 17th Bengal and 28th Bombay Native Infantry, with some mounted infantry and a small body of the 5th Lancers, and some thirty-two Blue-jackets, had reached a spot five miles and three-quarters S.S.W. from the camp, quite unmolested by the enemy, and were there halted, for the purpose of making a zereba out of the bushes growing in the immediate locality. At this time the camels and mules carrying water and provisions, with their Indian and Maltese drivers, had not yet reached the *locale* selected for the camping ground, but were coming up in detachments and groups, the line of their somewhat irregular formation extending a considerable distance in the rear. The mounted scouts were out searching for the rebels; and so much security from any sudden attack was felt by those in command, that the men's arms were piled and the ammunition placed outside the half-finished zereba in one spot, whilst many of the Sappers were unarmed, cutting brushwood, some 400 yards away in another. The greater number of the soldiers thus employed were in their shirt-sleeves, and possessed no weapons of defence save the spades and pickaxes they had in their hands. Working under the scorching rays of a vertical sun, they little dreamed their foe was so near them. At this juncture an alarm was raised, the mounted scouts giving notice of the enemy's presence and rapid approach upon our position and half-finished zereba; but the warning was not in sufficient time to avert the disaster that speedily followed; nor could any means be taken to check the on-rush of their impetuous charge before many of their brave fellows had not only reached, but gone clean through, the British half-formed square. Fleet of foot—their speed even exceeding that of our troopers' horses—and courageous as lions, on they came bounding, yelling horribly, and brandishing their spears and sharp-edged swords. Their onslaught was so unexpected and so determined that, for a few minutes at least, everything seemed to fall beneath their vigorous and well-timed attack. Amidst a scene of the wildest confusion, and enshrouded in a towering column of thick dust that arose on all sides, our men were rushing here, there, and everywhere but in the right place—of course, to search for and regain possession of the arms left far away from them at the commencement of their work. What followed will long be remembered by those who have been spared, but who were unfortunate enough to have taken part in this most calamitous affair. Camels, cut loose, and disembowelled by the fiends creeping beneath them and ripping open their abdomens with short curved swords, were racing in maddening agony over the plain; whilst riderless horses and mules, whose unarmed keepers and attendants had by this time all been shot or speared by the Arabs, were kicking up their heels and scampering away in all directions, making confusion worse confounded by their snorting and hideous noises. Half-dressed semi-armed men were (hotly pursued by the foe) making for points where rallying squares could be formed by their officers; whilst fugitives—press correspondents among them,—better mounted than the rest, and unable to get within the squares, were seeking the more congenial safety of strategical retreat in a racing dash for it across country in the direction of Suakim and the entrenched camp some five miles in the rear. The 17th Bengal Infantry, unable to withstand the impetus, commenced falling back in disorder, whilst officers, men, and camp-followers were on all sides trying to get within the shelter of the forming square. One officer, a member of the medical profession, unarmed, lost his horse under him, and at the same time saw his servant and also his orderly shot dead by his side. Seizing an axe, in the absence of sword, revolver, and ammunition, he laid it about him with such dexterity and effect that he kept his antagonists at bay, got within the square, and, happily unscathed, came into camp with the wounded next day. A small unfinished sand-bag redoubt occupied by the Naval Brigade, under the command of Lieutenant Seymour, suffered terribly. Out of the nine persons there, six were killed, one was wounded, and two escaped. Poor Seymour's body presented a shocking spectacle of spear and sword wounds. Pen cannot describe the doings of that momentous Sunday forenoon's work. To avert an overwhelming calamity something had to be done, and that very speedily too. The Berkshire Regiment, the Marines, as well as the brave Sikhs, were equal to the occasion, and proved true to the core. By their steadiness and bearing under most trying circumstances the enemy were for a few minutes held in check, and some order was restored. Our boys, rallying, fell into something like fighting position, and, standing shoulder to shoulder, poured in such a destructive and deadly hail of bullets upon the advancing line of these poor fanatical, yet withal bravest of the brave, savages, that the battle was saved and the day won, and the dark legions of Osman Digna were hurled back once more to the limited shelter of the mimosa-bush, whilst the withering fire of our marksmen strewed the yellow sand with corpses, and reddened its surface with the blood of the wounded and slain. Twenty minutes' action, and the fight was over. In that brief space of time what blood had been spilt and what treasure had been lost! Rifles, spears, and swords had done their murderous work so well and so effectively that the ground was strewn with the mangled and slain, whilst a death-roll of 118 and a list of wounded to the extent of 160 men on our own side testify to the impetuous and desperate character of this affray.

A camel train of about 1000 strong a few days ago is now a thing of the past, whilst it would commercially repay any man of energy and strong nerve—if utterly regardless of his own life—to make an excursion from here to the zereba, and collect the transport boxes, water barrels, &c., scattered along the line of retreat of our poor unarmed and scared camel and mule drivers, who, on the first rush and surprise, were forced to desert their charges, seek some protection, make for some place of safety, and leave their costly articles of commissariat to the tender mercies of a temporarily victorious foe.

Many are the gunshot wounds amongst the wounded, yet the enemy are supposed to have but few rifles (Remington's), and these were secured at the defeat of Hicks's army; but those they possessed must have been used with an accuracy of aim and precision of fire unprecedented in the records of target practice; whilst the extraction of some Martini-Henry bullets from our men cannot be explained except on the presumption that the enemy are already in possession of a fair supply of these more modern, invaluable, and long-range weapons. Sunday's fight has already taught one lesson—that our camel and mule drivers must no longer be permitted to go without weapons, for one can well understand the hesitation (begotten of no spirit or unmanly fear) shown by these unarmed followers to accompany the force again, unless better protected on their flanks and in their rear, with the prospect of provoking a conflict in which they are certain to find themselves worsted by so active, so well armed, and implacable a foe.

To the chivalry of our own men alone can be ascribed the success of Sunday's fight, at one time so doubtful. Soudanese mothers, wives, and relatives have now to mourn the loss of about 2000 warriors, lying bleached and decomposed on that gory, trampled plain. Such are the results of this horrible war, and such the outcome of that religious fanaticism which carries these poor creatures to their desperate fate, and urges them heedlessly on to their inevitable doom. But what of 'Christian chivalry, supposed to be so characteristic of our time and age? If it in any way influences men to do their duty whenever and wherever they may be sent, does it not also make them shudder at times, when called upon in the performance of that duty, to mow down in hundreds, nay in thousands, such brave misguided fanatics; because we are invading, they as-patriots (they are in reality such) are defending their own country and her most uninteresting cause? England's bravest deeds in this unhappy land were well unwritten indeed; the best results, the most brilliant achievements, will carry little weight with them hereafter; and when sufficient blood has been poured out and treasure lost, the *finale* will be discouraging enough to stamp with a big blot those pages of England's military history in this sun-scorched land. Besides the 118 killed amongst our naval and military officers and men, about 300 or more of our Indian coolies and European mule and camel drivers and attendants are missing since the disastrous Sunday's engagement. About the fate of these poor fellows there can be but one opinion—all slain to a man. The enemy gives no quarter whatever.

But enough of this: let me for a moment turn to the brighter and philanthropic side of this dismal and bloody picture, and say a word or two about the sick and wounded. Being an eye-witness of what took place (down at the excellently arranged Base Hospital) on the Monday after the fight, I am able to show you every possible contingency was provided for; how faithfully a small band of skilful surgeons, under the direction of Brigade-Surgeon Tanner, provided for the reception and comfort on arrival of those stricken down in yonder plain; how, though these poor wounded men came into camp late in the evening, they were received with humanity and every possible care; how each medical officer during the previous afternoon had received a notification to have ready a supply of hot coffee and beef-tea, brandy-and-water to be given to each patient after being placed in nice clean soft beds. Nothing could be better than the arrangements made by the medical staff on behalf of the poor sufferers.

Up to this date, March 27th, since the establishment of the Base hospital at H redoubt, there have been 137 admissions; of this number 64 have been transferred to the *Ganges*, and five have died, three from wounds received in action and two from sunstroke. The rest remain under treatment. Of amputations performed, there have been four arms, four fingers, one thigh, and one leg. Of these only one has died after operation. The previous admission list does not include marines and sailors; of these twenty-seven have been received, one of them dying from gunshot-wound in the thigh. Up to date there have been eight cases of severe sunstroke, and of these, as before mentioned, two have died.

Before closing this letter I may mention that several of the Sisters under the superintendence of Miss Ireland have arrived, and are severally located at the Base Hospital, *Ganges*, and auxiliary depot. They look remarkably well after their sea trip. Their presence seemed to quite cheer up the poor wounded and sick fellows. I sincerely trust they may stand this climate. Temperature in the shade 80°, in the sun 94°. The nights are cool and pleasant.

The following is the disposition of the medical staff:—

Surgeon-General O. Barnett, principal medical officer at Headquarters Camp.

Surgeon-General G. L. Hinde, superintendent at Base, H. Redoubt, and Quarantine Island.

Surgeon-Major J. Warren, sanitary officer, Headquarters Camp.

Surgeon-Major H. Tanner, sanitary officer, Base and H. Redoubt.

Surgeon-Major J. B. Hamilton, field inspector detailed for hospital organisation on line of communications.

Surgeon-Major H. Tobin, operating surgeon at Base and H. Redoubt.

Surgeon-Major A. Allan, registrar at Base and H. Redoubt.

Surgeon-Majors at Base Hosp., H. Redoubt: T. W. Patterson, J. G. Barrow, S. K. Cotter.

Surgeon-Majors at Stationary Field Hospital: H. H. Stokes, G. Carey, J. J. Cream.

Surgeon-Majors, Hospital Ship *Ganges*: H. Gribbon, E. P. [illegible].

Surgeon-Majors at Guards' Hospital (their own): H. J. [illegible], A. R. Meyers, C. C. Beal. 4th Guards' Field Hospital: S. G. Robinson.

Surgeon-Majors and Surgeons to 1st Field Hospital: J. H. [illegible], F. Kingston, W. J. Rourke.

Surgeon-Majors and Surgeons to 2nd Field Hospital: J. Flemming, H. L. Donovan, R. Smith, S. G. Freyer.

Surgeon-Majors and Surgeons to 3rd Field Hospital: H. J. Riordan, H. Bates, H. N. Johnston, N. Maunders.

Surgeon-Majors and Surgeons to No. 1 Bearer Company: H. J. Wilson, J. R. Collins, C. Bert.

Surgeon-Majors and Surgeons to 2nd Bearer Company: E. J. H. Evatt, W. Keys, R. J. D. Hackett.

Surgeon-Major Cream (sanitary), at Base.

Sixteen other surgeon-majors and surgeons attached to their various regiments; also two naval medical officers doing duty on shore. In addition, Professor Ogston and myself.

The following cases, which came under the care of Surgeon-Major Samuel Kyle Cotter, are worthy of record:—

Gunshot Wound; Fracture of Arm; Amputation.—Private E. C——, Royal Marines, was wounded on March 20th by a bullet which passed through the middle of his left arm, shattering the bone upwards and downwards for about the space of four inches. On the 21st, under ether, examination revealed the hopeless shattering of the bone, and amputation was performed by Surgeon-Major Tobin at the junction of the middle and upper thirds. The temperature before operation was 99·1°, and soon after it fell to 98°. The operation was by anterior and posterior flaps, and the bone was sawn at about three inches below the head, up to which point splintering existed. A drainage-tube was placed through the wound at the outer angle, and the whole dressed antiseptically. He was restless all day, but the pulse did not rise beyond 88. At 9.30 P.M. one-third of a grain of morphia was injected hypodermically, and he passed a very fair night. On the morning of the 22nd the temperature was 99·2°, the pulse 96. Since the operation there had been difficulty in passing urine, and the catheter was required. In the evening of the 22nd the temperature was 99·8° and the pulse 93. On the 23rd the dressings were renewed, and the wound showed a tendency to heal by first intention. Temperature 99·2°; pulse 80; bowels confined. To have an enema of sulphate of magnesia at once. Catheter still required. In the evening of the 23rd the temperature was 100·2°, and the pulse 84, with a tendency to hardness.—24th: Temperature 99·2°; pulse 79, and hard. Not a good night; but little pain in the stump now. Evening temperature 100°; pulse 78; urine passed freely.—26th: Dressings and drainage-tube removed, and the stump again dressed under carbolic spray. Union by first intention established almost throughout. On this day he was cheerful and able to sit up, and was transferred in the evening to the hospital ship *Ganges*.

Sunstroke.—No. 73, Corporal (name unknown), Royal Engineers, contracted sunstroke during the action of the 20th of March, and was brought to the Base Hospital at 6 P.M. on the 21st. He lay speechless and still; the eyeballs turned somewhat upwards, the upper lids immovably elevated, and the pupils dilated to their fullest extent. At about 6.30 P.M. a convulsive attack came on, and he voided a most profuse quantity of thin, dark, grumous fæces, with a fœtor of the most intolerable character, the sickening odour of which was beyond description. The muscles of the chest, abdomen, and arms were affected by the convulsions, but not those of the back and legs. Though he lay perfectly straight and rigid, there seemed to be no opisthotonos. The convulsive attacks soon began to recur at short intervals, and a slight touch, merely, of the skin sufficed to bring them on. The hands eagerly grasped any article, and on attempting to withdraw it the grasp became stronger and the shaking and convulsion increased, whilst at the same time it is believed that he remained entirely unconscious. The bowels continued to discharge, and nearly a gallon of this grumous matter must have passed. Urine was drawn off with a catheter in immense quantity. The temperature was 103·3°, and later on rose to 104·5°, the pulse being all along about 130, and intermittent every fifth or twelfth beat. During the convulsions he screamed loudly. The convulsive attacks getting more prolonged, and interfering so much with respiration, inhalation of chloroform was resorted to. Under the use of this the convulsions ceased or were controlled, the pupils contracted to nearly their natural size, and the pulse became fairly full, slower and intermittent, but at long intervals. Two ounces of brandy were given and swallowed well; also beef-tea. At 1 A.M. on March 22nd the pulse began again to flutter and intermit. A sinapism was applied to the præcordia and epigastrium, and an enema of beef-tea and brandy administered. He continued to moan, but had no convulsions to speak of. The pupils again became dilated, and most profuse sweat—not cold—bathed the whole body. He became unable to swallow, and sank at 3A.M. A case exactly similar occurred at the same time in the next tent, but the man died about two hours after admission.

LIVERPOOL.

(*From our own Correspondent.*)

THE PREVENTION OF CRUELTY TO CHILDREN.

Two years ago a Society was formed here for the prevention of cruelty to children, and its first annual meeting was held in March, 1884. Similar societies have since been formed in London, Manchester, Edinburgh, and Glasgow, all of which have adopted the rules of our local society. At the second annual meeeting of the latter, held on the 20th inst., it was stated in the report that, during the year, complaints had been dealt with by the Society involving the welfare of 844 children. Speaking generally, the cases were more those of gross neglect than of active and deliberate cruelty. In fourteen cases the parents were prosecuted and punished. The condition of the children in the streets of Liverpool has long been a reproach to the city, and it was hoped that the School Board would be the means of effecting an improvement. The evil was one, however, with which they had no power to deal; hence, the new Society has a noble work to perform, and it is being vigorously taken in hand. No class of men know how much unpunished cruelty to children goes on so well as medical practitioners, especially those who hold parochial appointments. These children by their miserable appearance excite sympathy, and with the money received from charitable persons often maintain their drunken and idle parents. A great effort is being made by the head constable to suppress mendicity, and when it is found to be unprofitable much of the present cruelty to children will cease.

COURTS OF LAW AND FETID ATMOSPHERE.

Mr. Justice Wills has severely censured the authorities in Manchester for the very inadequate arrangements made for the accommodation of prisoners awaiting trial. That which is provided in our local courts is superior to less modern courts, but it must be frankly admitted that the accommodation for witnesses is very deficient. Medical and other witnesses awaiting their turn to go before the grand jury are huddled together at the top of a staircase and along a corridor where the atmosphere is most vitiated. This ordeal passed, the medical witness has to choose between the corridors, the outside of the building, or the body of the court, the general waiting-room being quite out of the question. In the Crown Court itself the atmosphere becomes very vitiated even on a winter's day, and in summer time almost intolerable, except to those who are well acclimatised to it. The radical defect in our assize and police courts is a want of sufficent escape for foul air at the top of the building. It is not many years since the late Mr. Justice Heyes fell a victim to the polluted atmosphere of the court in which he had been presiding, and there can be little doubt that many an illness has arisen from being required to attend court as juror or witness.

THE STIPENDIARY MAGISTRATE AND CASES OF BITING.

At the police-court on Monday last, a respectably-dressed man, who had hitherto borne a good character, was charged with an assault upon a city constable, whose hand he had bitten, besides inflicting sundry bruises. The magistrate, on being asked by the prisoner's solicitor to deal summarily with the case, declined to do so, remarking that it was his determination to send all such cases to trial, "as cannibals deserved more severe punishment than he was able to award them."

CORONERS, MEDICAL WITNESSES, AND POST-MORTEM EXAMINATIONS IN WORKHOUSES.

The result of the Croydon Workhouse case will be watched with considerable interest by practitioners here as elsewhere. In the Liverpool Workhouse there are, on an average, at any given time, 2500 inmates. As may be readily understood, among such a number inquests will occur frequently in the course of the year, and the resident medical officers have invariably been paid for attendance and for making autopsies. To require them to undertake such additional work gratuitously would be manifestly unfair, as well as contrary to the understanding which regulates the acceptance of such appointments.

Liverpool, April 22nd, 1885.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

DURHAM UNIVERSITY.

Certain important alterations were made at the late convention of this University in the regulations respecting the degree of Bachelor of Medicine. Henceforward every medical student will have to pass a preliminary examination in general knowledge, including the English language and history, arithmetic, geography, and Latin; and candidates for the degree of M.B. will have to be of the standing required for admission to the licence in Medicine, and must have fulfilled similar conditions as regards residence and attendance on lectures and hospital practice during four years.

THE PROPOSED FLOATING HOSPITAL FOR THE TYNE.

At a late meeting of the Tyne Commissioners notes were submitted in reference to the new floating hospital. The city engineer proposed to float it upon circular pontoons, placed ten feet apart, and surmounted upon a platform of iron and timber. These pontoons would be so arranged as to carry the platform about four feet above the water level. It was proposed to have three large wards, with ten beds each. The wards would of course be of wood, doubly lined. The roof would be of zinc or wood. Space was provided on the proposed platform for the future erection of the administrative block; but the cost would not be included in the present estimate. The cost of the hospital would be £4000.

THE NEW ETHOXO LIME-LIGHT.

At a late meeting under the auspices of the Northern Counties Photographic Association, held in the theatre of the Newcastle Literary and Philosophical Society, a paper was read upon the new Ethoxo Lime-light by the Rev. F. T. Hardwick, which is claimed to be equal in lighting power to the oxyhydrogen light, and more safe and convenient. A letter was read from Professor Herschell testifying to the safety of the improved ethoxo light under tests of exceptional severity. Mr. Hardwick showed slides of insect life, &c., by aid of this light, and his demonstrations were admitted to have been very interesting and successful.

THE WATER-SUPPLY OF NEWCASTLE.

Some of our local papers are pointing out that the water-supply to our Tyneside towns is beginning to take a rather serious aspect. The population supplied by our waterworks is 770,000, and it is calculated that we have only 900 million gallons in store, against 2000 million gallons at the same period last year. At this rate our store will be exhausted in four months—that is, by the end of July. Of course we have the Tyne to fall back upon, but this source is open to many objections, and at present it is only pumped to meet trade demands. It is to be hoped that "a great many things may happen" before we have to resort to the Tyne for drinking purposes.

PRISONERS DYING IN GAOL.

The death of a prisoner under sentence, perhaps for some comparatively trivial offence, always produces a painful sensation. A case came before the coroner at Durham lately, in which a prisoner convicted of begging under false pretences died in gaol, after the expiration of his sentence. It was shown that on admission he was examined by the prison surgeon, who, finding him in an advanced state of pulmonary consumption, had him removed to the hospital in the gaol. He became gradually worse, and although his sentence had expired and it was intended to remove him to the workhouse, he succumbed to the disease before this step could be carried out. It was shown at the inquest that everything possible had been done for him from the first; still the coroner pointed out that this was another case which showed the necessity of there being some other place than a prison for the reception of dying persons convicted of crime. Another point was alluded to—namely, that the

Durham prison is too far away from the railway station for weakly people, and that there is no prison van for their conveyance. Cases have occurred of prisoners dying soon after admission to the gaol.

Newcastle-on-Tyne, April 21st.

EDINBURGH.

(*From our own Correspondent.*)

MEETING OF EDINBURGH UNIVERSITY GENERAL COUNCIL.

THE statutory half-yearly meeting of the General Council was held on Tuesday, the 21st instant. Lord Inglis, the Chancellor of the University, presided, and was supported by the Principal, Sir William Muir, and several of the professors. The whole interest of the meeting centred in the question of University reform, and there were several motions on the orders of business which had reference to the Universities (Scotland) Bill, 1885. The first was moved by Mr. Taylor Innes, Advocate, approving the general scope and principle of the Bill, and proposing to petition Parliament in favour of its early passage into law. In bringing forward this motion, Mr. Innes said that, in his opinion, there were clauses in the Bill which would require amendment in passing through committee, but that it should be supported, as it provided for many useful reforms, amongst which he might cite the scope of those clauses which endow the Commissioners under the Act with powers of adding to the functions of the General Council and increasing its power, of further developing the range of extra-mural teaching, and of providing for the University education of women. Amidst loud expressions of varied opinion on this point, Mr. Innes expressed the hope that the University curricula would soon be thrown open to the other half of the human race. He also drew attention to the fact, that in the present Bill the finality clause as regards the limitation of Government support to Scottish Universities has been abandoned, and this he urged as an additional reason for supporting the Bill as at present drafted. Mr. McKie proposed an amendment, approving the clauses which increase the powers of the University Court and the General Council, but opposing the Bill as a whole unless greatly modified. The amendment was rejected, and the motion carried by a large majority. Professor Laurie brought forward a motion urging upon the Government the reconsideration of the clauses which transfer the Observatory and Botanic Gardens to the University, providing for the payment of pensions by the Senatus instead of by the treasury, and transferring the patronage of bursaries from various private individuals and corporate bodies to the Senatus. After prolonged discussion this motion, with a slight modification, was agreed to. Professor Masson then opened a discussion of some importance upon the question of an increased teaching staff within the University itself. At the meeting of Council held last October a general motion in favour of increased facilities for extra-academical teaching had been adopted; and the present motion, while conceding the importance of that element, urges that attention should also be paid to a scheme for greatly enhancing the teaching power of the University within its own economy by adding to the numbers of its teaching staff. This, Professor Masson thinks, should be carried out on the German *privat docent* system; and he advocates an advance in the status of assistants to professors, and of their emoluments, as the best means of accomplishing this object. Mr. Scott Dalgleish proposed an amendment reaffirming the position taken by the Council in the matter last October. An animated discussion ensued, followed by a division, when the amendment was declared to be carried by 26 votes to 22. Several members present abstained from voting. This result was largely due to the vote of the medical graduates present, many of whom are themselves engaged in extra-mural teaching in the Edinburgh Medical School, and who view with distrust any proposals tending to diminish the importance which the extra-academical school at present possesses in relation to medical teaching in Edinburgh.

SUPERANNUATION.—Mr. Arthur Priest, late medical officer for the Waltham Abbey district, Edmonton Union, has received a superannuation allowance of £71 8s. a year.

IRELAND.

(*From our own Correspondent.*)

ROYAL UNIVERSITY OF IRELAND.

As the undergraduates of the University of Dublin have been granted a term, a memorial is about to be presented to H.R.H. the Princess of Wales, praying that she may be pleased to ask the Senate of the Royal University to grant a similar favour to the undergraduates of this University. Honour students will not feel this concession, if granted, in any way a hardship, as they will, as usual, have the right to compete for exhibitions. Steps are being taken to place the matter under the Royal notice before the return to England.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At the last meeting of Council the President read a letter from Dr. Cameron, the Vice-President, stating that, having suggested the idea of erecting a marble statue to Mr. William Dease in the College, Mr. M. O'Reilly-Dease, D.L., a grandson of the celebrated surgeon, had offered to defray the entire cost of erecting the monument, and had given him (Dr. Cameron) *carte blanche* to make all the arrangements. We understand Dr. Cameron has selected Mr. Thomas Farrell, the eminent sculptor, to carry out the work, which will at once be commenced. On the motion of Mr. Colles, seconded by Sir G. H. Porter, Mr. O'Reilly-Dease's generous offer was thankfully accepted.

ALTERATION OF IRISH PRISONS RULES.

By an Order in Council the Lord-Lieutenant has approved of certain rules made by the General Prisons Board for Ireland in relation to the duties of surgeons to prisons. These are as follows:—1. That no irons or means of mechanical restraint shall be used, excepting such as are approved by the Lord-Lieutenant, or such as may be considered necessary by the medical officer to be used as medical appliances in the case of violent prisoners in hospitals. 2. The surgeon shall visit the prison once each day, and not later than 12 o'clock noon, and oftener if necessary; and shall see every prisoner in the course of the week. He shall daily visit the prisoners, if any, confined in punishment cells or under punishment in their own cells, or under mechanical restraint; and he shall visit daily, and oftener if necessary, such of the prisoners as are sick, and when necessary shall direct any prisoner to be removed to the infirmary. 3. The surgeon shall, whenever he considers a prisoner's life to be in danger by further confinement, at once report the fact to the Under Secretary for the Lord-Lieutenant's information, and also to the General Prisons Board and to the governor; and he is also to report to the governor the case of any prisoner to which he may think it necessary, on medical grounds, to draw attention.

THE TREATMENT OF INTERNAL ANEURYSM.

In a paper read by Professor Finny at the last meeting of the Pathological Section of the Academy of Medicine in Ireland, the treatment advocated by Mr. Tufnell of Dublin was highly recommended. Mr. Tufnell, who was present, made a very interesting communication in reference to his treatment in cases of internal aneurysm, and particularly insisted on rest in the horizontal position for a considerable time as a most important element in these cases. He referred to two cases of well-marked abdominal aneurysm, the subjects of which were now in excellent health, one after five years, and the second after seven years, since his mode of treatment had been used.

Dublin, April 21st.

PARIS.

(*From our Paris Correspondent.*)

THE NATURE OF THE CURVED OR COMMA BACILLI.

AT the meeting of the Académie des Sciences last week Professor Richet read a paper, in the name of M. J. Héricourt, on the nature of the curved or comma bacilli and on the presence of their germs in the air. The following are the conclusions of the author:—1. In all waters, whatever be their quality or origin (springs, drains, wells, cisterns, &c.), there exist curved bacilli of variable forms and dimensions, among which those of the type that are described as choleriform are constantly found. 2. The curved bacilli do not exist in the atmosphere under their characteristic form; they are there found in a state of germs, under the form of spores. 3. The intestinal dejections in simple diarrhœa, as well as in dysentery and typhoid fever; the broncho-pulmonary secretions in the various diseases of the lungs, in pus exposed to the air, human saliva, whether normal or abnormal—all substances, in fine, that are susceptible of serving as nutriment to germs or bacteria, contain curved bacilli. 4. These curved bacilli are strongly aërobied, and it is only at the surface of liquids that they are to be collected. They are very mobile. They are agitated by rapid oscillations, exactly similar to those of vibriones, and are endowed with a strong power of refraction. They are about half or two-thirds of the length of the bacilli found in tuberculosis, and are thicker and less regular than the latter. Nothing differentiates them from the bacilli that are found in the dejections of cholera patients. 5. In awaiting inoculations more conclusive of their pathogenic *rôle* being performed with the comma bacilli collected in the intestines of cholera patients, the conclusion to be drawn from the propositions that precede is that these micro-organisms are the same as those that are found in all secretions, whether normal or pathological, on the only condition that these secretions have been found in contact with water in which the curved bacilli are the habitual occupants, or with the air which conveys their germs.

THE REMOVAL OF A CANCEROUS KIDNEY.

Wishing to know the cause of the omission on the part of Dr. Péan to state whether the operation of gastrotomy, referred to in my letter of the 11th inst., was performed under the influence of chloroform or other anæsthetic, or whether antiseptics were employed or not, I wrote to him on the subject, and received for answer, "Inutile de vous dire que je soumets à l'anesthésie chloroformique toutes les malades auxquelles je pratique la gastrotomie, et que je me contente, à la suite de l'opération, de l'appareil ouaté compressif et du pansement par occlusion de Chassaignac comme je l'ai fait depuis 25 ans, sans autre précaution antiseptic. J'ai rejeté depuis longtemps le 'spray' comme étant plus dangereux qu'utile dans ces sortes d'opérations." I may here add that the patient who was the subject of Dr. Péan's communication was herself presented to the Academy of Medicine. She was thirty-six years of age. She also formed the subject of a clinical lecture by Dr. Péan, which will be found embodied in vol. iv. of his "Cliniques de l'Hôpital Saint Louis," about to appear. The lesson taught by this case is, according to the author, that in the presence of large malignant tumours of the kidneys, the course of which is not hyper-acute, one should not despair of cure. I may here also add that in the case under notice it was the right kidney that was removed.

MM. CHARLES ROBIN AND CORNIL.

By a special decree in their favour MM. Charles Robin and Cornil, Senators, have been allowed to retain their respective positions at the Faculty of Medicine of Paris, the former as Professor of Histology, and the latter as Professor of Morbid Anatomy.

Paris, April 21st.

THE SERVICES.

War Office.—Army Medical Staff: The undermentioned officers are granted retired pay, with the honorary rank of Deputy Surgeon-General:—Brigade Surgeon William Gerard Don, M.D., Brigade Surgeon Samuel Stacy Skipton, M.D. The undermentioned officers are granted retired pay with the honorary rank of Brigade Surgeon:—Surgeon-Majors James Edward Clark, William George Ross, M.D.; John Anderson, C.I.E.; George Francis Dooley, Eugene Robert O'Brien, M.D.; and John Norman Davis, M.D.

Indian Medical Department.—Deputy Surgeon-General Michael Cudmore Furnell, M.D., F.R.C.S., Sanitary Commissioner, Madras, has been appointed Surgeon-General with the Government of Madras; Deputy Surgeon-General George Bidie, M.B., C.I.E., has been appointed Sanitary Commissioner, Madras; Surgeon Hazlett Allison, M.D., has been appointed Assistant Physician, Madras General Hospital; Brigade Surgeon J. McN. Donnelly, M.D., has been promoted to be a Deputy Surgeon-General, with permanent rank.

Admiralty.—The following appointments have been made:—Surgeon Francis H. Julyan, to the *Triton*, additional; Fleet Surgeon James Trimble, to the *Asia;* Staff Surgeon James Robertson, to the *Conquest;* Fleet Surgeon Robert Nelson, to the *Thunderer;* Staff Surgeon Michael Fitzgerald, to the *Orion;* Surgeon Edward G. Swan, to the *Thunderer;* Surgeon Denis W. Donovan, to the *Alexandra*, additional. Staff Surgeon William Henry Stewart, M.B., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

Yeomanry Cavalry.—Middlesex: Surgeon Thos. William Thompson resigns his commission.

MEDICAL NOTES IN PARLIAMENT.

The Poisons Bill.

In the House of Lords on the 20th inst., Lord Carlingford having moved that the Poisons Bill be referred to a Select Committee, the Earl of Milltown, who had given notice that on the motion for going into Committee on the Bill he would move, "That the House resolve itself into Committee on the Bill this day six months," said he felt very strongly that a measure on this subject was necessary, right, and proper. At the same time, however, he was of opinion that the Bill now before their lordships was not a good one, and that it was extremely likely to harass and hamper legitimate trade. It had been brought forward without any reference to the interests of the trade or to the interests of the public, and on that ground he appealed to the noble lord some time ago to refer it to a Select Committee. The noble lord had now done so, and he would, therefore, withdraw his notice on the paper. The motion was carried.

The Expenditure of the Eastern Hospitals.

In the House of Commons on the 20th inst., Mr. G. Russell, in reply to Baron H. De Worms, stated that the Local Government Board had been asked by the Metropolitan Asylums Board and several Boards of Guardians to institute an inquiry into the expenditure of the Eastern Hospitals, and the inquiry has been intrusted to three of the Board's inspectors, Mr. Hedley, Dr. Bridges, and Mr. George Taylor.

Pauper Lunatics.

On the 21st inst., Mr. G. Russell, in reply to Mr. J. Talbot, said the question of detaining pauper lunatics in workhouses, in view of the recent decisions of magistrates on the subject, was being considered in connexion with the Lunacy Bill which had been introduced into the House of Lords by the Lord Chancellor.

The Health of the Troops in the Soudan.

The Marquis of Hartington, in reply to Sir F. Milner, said that from the circumstances under which our forces were now placed in the Soudan, it was scarcely possible to state the exact percentage of sickness. On the whole, however, the health of the troops was reported to be good. They had not received any accounts showing that an extraordinary amount of suffering prevailed among the troops on the Nile. All the arrangements for the accommodation of the troops were made locally. Large supplies of clothing and other requisites had been sent out, but it would be impossible to state how far the means of transport at the disposal of the authorities in Egypt enabled them fully to reap the advantage of such arrangements.

Private Lunatic Asylums (Ireland) Bill.

On the 22nd inst. Mr. Corbet moved the second reading of this Bill, the object of which, he said, was gradually to get rid of private asylums kept for pecuniary profit, which was reported to be at the root of all the evils connected with private asylums in Ireland. Mr. Campbell-Bannerman said that the Government had introduced into the other House a Bill dealing with the subject of lunacy on different lines from this Bill, and it would be impossible to be legislating at the same time upon one system in the other House and upon another system in this House. He knew and admitted all that could be said in favour of doing away with private asylums; at the same time to get rid of them in a summary way would raise large questions of compensation. The hon. member assumed that asylums would be self-supporting if they were erected, but money would be required to erect them. The hon. member said he would get it from the

Church Fund Surplus; but to the best of his belief there was nothing to be obtained from that source. The Bill was lost by a majority of thirty-five.

Mr. Acland moved the second reading of the Public Health (Members and Officers) Bill, which after some discussion was read a second time.

Obituary.

OSWALD GEORGE DYX BRADSHAW, M.R.C.S., L.R.C.P.

THE death of Surgeon Bradshaw at Korti, March 13th, 1885, from enteric fever, has created a feeling of the deepest regret. He was beloved and respected by all with whom he had occasion to become associated, and, though but a young man, his professional and social merits had secured for him a large circle of friends. He was the youngest son of the late Capt. L. A. Bradshaw, Royal Artillery, and was born in 1859, at Secunderabad. He was educated at Wellington College, and entered the British Medical School in 1876; subsequently becoming a student at St. George's Hospital in 1878. At the latter institution he obtained the Brackenbury prize in medicine, and passed first in the Army Medical Service at the August examination, 1883. At Netley his career was marked by the same devotion to work, and he was rewarded by gaining the Martin Memorial Gold Medal for proficiency in Military Hygiene, and the Director-General's Prize for Pathology. In September, 1884, he obtained his commission, and sailed for Egypt, where he was actively employed at the front, and was untiring in his care of the sick. The fever was probably contracted by the bad water and fatigue incident to a long march across the desert. In him the service has lost a brave and faithful officer, the profession a useful member, and his friends a genial and pleasant companion.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following candidates passed the Primary Examination in Anatomy and Physiology for the diploma of Member of the College at a meeting of the Board of Examiners on the 8th inst.:—

ANATOMY AND PHYSIOLOGY.—Joseph Beadle, Newcastle and Glasgow; G. Hamerton Rowlands, O. Taunton Stephenson and Charles W. Graham, Liverpool School of Medicine; J. Price Williams, Percy Ashworth, Herbert Wade, and Arthur M. Cass, Manchester; George A. Ferraby, W. Matthew Joyce, and Leslie Whitehead, Birmingham; T. Mayo Stiles, G. Henry Skinner, F. Horace Hudson, and Frank Calden, Bristol; Percy R. Gostling, T. H. Fencott Evans, A. Knight Holt, and Edwin C. Palmer, St. Bartholomew's; Herbert J. Roper, J. Arthur Smith, and Henry Goot, Leeds; Patrick Hehir, Edinburgh and Calcutta; P. J. Mader, Edinburgh; M. Mitchell Bird, St. Mary's; William Branson, Sheffield; George Cherry, Toronto.

ANATOMY ONLY.—Lewis L. Bailes, Newcastle; A. Dunley Owen, Bristol; W. Matthews Joyce and J. Hazlewood Clayton, Birmingham; A. Morton Barford, St. Bartholomew's.

(Candidates referred for three months, 5; six months, 4.)

Passed on the 10th inst.:—

ANATOMY AND PHYSIOLOGY.—W. Bickward Bacot, R. William Boyce, University College; Christopher P. Spink, W. Barker Russell, and H. Clifford Baldwin, Leeds; M. Prentice Ledward and J. Harwood Wilson, Manchester; A. Edward Leitch, J. Hepworth Shaw, G. William Chaster, W. Edward Livesey, and J. Webster Shannon, Liverpool; E. Lyall Haynes, L. William Andrews, L. Emilius Jowers; Thomas Lissaman, T. William Kelly, and B. A. Farrar, St. Bartholomew's; J. W. B. Pegram, E. Alfred Sadler, G. T. Congreve Barker, and H. Wynne Thomas, Birmingham; J. Smith Bootman, Newcastle; John Stokes, Sheffield; G. Herbert Pennell, Guy's; W. M. F. Nelson, Montreal; H. Stanfield Collier, St. Mary's; Benjamin Walker, London.

ANATOMY ONLY.—R. Hamilton, Bristol; A. E. D. R. Peters, St. Bartholomew's; J. A. Eyton-Jones, Liverpool; J. E. Foster, Birmingham.

PHYSIOLOGY ONLY.—R. B. Smith and J. W. Whitehead, Manchester.

(Candidates referred for three months, 6; six months, 2.)

Passed on the 11th inst.:—

ANATOMY AND PHYSIOLOGY.—W. Arthur Hooton, Richard Alcock, J. Watson Lonsdale, and J. F. Woolhatt, Manchester; F. H. Whitehead, C. [illegible] and Manchester; J. Houghton White, Ernest [illegible], Henry Hawley, and W. Edward Hardy, St. Bartholomew's; [illegible], London; Percival E. Burnett, Middlesex; Charles [illegible], T. William [illegible], University College; Basil W. Hossman, [illegible], G. E. Keane, University College; and Ernest H. Snell, Birmingham; [illegible], Samuel Nicklin, and J. V. W. Rutherford, Edinburgh; Joseph [illegible] Keane, Liverpool; J. Wheeler and W. Job Maillard, Guy's; Frederick Lace, Bristol, Arthur Miers, Leeds.

ANATOMY ONLY.—George Thorpe, Sheffield; Arthur W. Hogg, St. Bartholomew's; Abraham J. Meuer, New York; Percy J. Spencer, London; Hubert Joslen, Guy's.

PHYSIOLOGY ONLY.—Herbert Burland, Manchester; F. S. Jermaine-Ludham, St. Bartholomew's; H. Cecil Nicholls, Charing-cross; Evan Jones, London.

(Candidates referred for three months, 2; six months, 2.)

Passed on the 13th inst.:—

ANATOMY AND PHYSIOLOGY.—R. Oxley Bowman, Jabez D. Windle, Daniel Booth, W. Leonard Bentley, E. Ernest Smith, and Arthur E. Giles, Manchester; G. Arbuthnot Robinson, London; Robert Bird, C. Stanstay Edwards, J. G. Ernest Colby, W. Norman Evans, John Rust, and T. William Francis, St. Bartholomew's; Henry J. Campbell and Morgan J. Morgan, Guy's; Frederick W. Stokes, Birmingham; Eric E. Kershaw, and M. Percy Cooke, Middlesex; Francis Naumann and Albert W. Cooke, Charing-cross; Richard P. Brooks, King's College; Stanwell Weldon and John Wayte, St. George's; W. Ap Samuel J. Graham, St. Mary's; T. Arnold Durrant, St. Thomas's.

ANATOMY ONLY.—William Rennie and J. Hurd Gordon, Birmingham; William Mortimer, London.

PHYSIOLOGY ONLY.—F. Cubbon Rogers, Manchester; C. L. S. James, London; A. F. Bilderbeck-Gomes, St. George's; Percy V. Dodd, St. Bartholomew's.

(Candidates referred for three months, 6; six months, 4.)

Passed on the 14th inst.:—

ANATOMY AND PHYSIOLOGY.—H. C. Leffler Arnim and Robert May, Charing-cross; Prideaux G. Selby, E. T. Mosse Tunnicliffe, A. Lindsay Travers, John W. Applegate, and A. Leonard Bright, St. Bartholomew's; H. C. Bristowe, R. Jackson Langley, R. Vaughan Solly, and E. Charles Mahany, St. Thomas's; H. E. Drake-Brockman, R. Staker Turton, and Beaumont H. Comerford, St. George's; James Wigg and J. H. E. Jarvis, London; Charles H. Buckley, James P. Walker, and George A. Berry, Manchester; Herbert E. Cuff, Guy B. Smith, and John D. Cruickshank, Guy's; C. Herman Fernan, University College; Howard P. Ward, King's College; W. Baron Cockill, Middlesex.

ANATOMY ONLY.—T. Owen Raw and Astley C. Roberts, Guy's; T. Alexander Murray, Manchester; M. Bayfield Dumaresq, London; Ernest Dawson, Westminster; James Daniel Brown and Cyril W. Shaw, St. George's; Alfred Bowles, University College.

PHYSIOLOGY ONLY.—P. Seymour Harris, Middlesex; W. Douglas Gimson, St. Bartholomew's; Lionel N. Hoysted, Charing-cross; Frank Elias, University College; G. W. B. Daniel, St. George's; George A. Slack, Guy's; Arthur Crook, London.

(Candidates referred for three months, 6; six months, 2.)

Passed on the 15th inst.:—

ANATOMY AND PHYSIOLOGY.—J. Auriol Armitage and T. Hamilton Ward, Edinburgh; J. George Carter, Charing-cross; Walter J. Bearblock, Walter Fisher, Joseph C. Baines, Ernest H. Starling, J. Vincent Blachford, and J. Low Aymard, Guy's; J. Llewellyn Rees, G. Gordon Parsons, and W. Burwell Darroll, London; E. Courtney Lomas, Marmaduke Bannister, Harvey Rhodes, and A. Baxendell, Manchester; E. A. Griffiths Dowling, Frank E. Gibbens, and George Heaton, St. Bartholomew's; H. Bryan Densham, Bristol and Edinburgh; W. Henry Vickery, R. Francis Thomas, and C. Lloyd Worrell, Middlesex; G. A. T. Bray and R. James Carter, King's College; E. Deanesley, University College; J. T. Bays, St. Mary's.

ANATOMY ONLY.—Walter S. Holford, St. George's; Harold Birkenhead, Manchester; T. Edward Pallett, Westminster; W. Wheldon Williams, University College; Jasper J. Garmany, Bellevue; James E. Brown, Toronto.

PHYSIOLOGY ONLY.—W. John Midelton and H. Y. Whitchurch, St. Bartholomew's; J. Wilkins, London; Malcolm E. H. Wale, St. George's; J. Douglas Cree, Middlesex; H. Foreman Cartmill, Manchester; Norman Davis, Newcastle; William Jones, University College.

(Candidates referred for three months, 4; six months, 1.)

At the recent Primary or Anatomical and Physiological examinations for the diploma of Membership of the Royal College of Surgeons, 387 candidates presented themselves. Of these 148 were referred.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following candidates passed the Second Examination (Anatomy and Physiology) on the 11th inst.:—

O. Le Mare Theobald, Walter Lovett Hubbard, H. H. Brodie MacLeod and Ernest A. W. Armstrong, King's College; Arthur W. James and W. P. Peake, St. Bartholomew's.

Passed on the 13th inst.:—

Herbert A. Smith and Edgar R. White, King's College; William Woodward, St. Bartholomew's.

UNIVERSITY OF ABERDEEN.—At the late medical graduation term, the following candidates, after the usual examination, received degrees in Medicine and Surgery:—

DEGREE OF M.D.

Brown, Clarence W. Haig, M.B., C.M., Godalming, Surrey.
Campbell, Alexander, M.B., C.M., Dundee.
Collie, Robert John, M.B., C.M., Aberdeen.
Cooper, William, M.B., C.M., Belhelvie.
Crow, Herbert William Tolver, M.B., C.M., London.
Gayton, Francis Carteret, M.B., C.M., Surrey County Asylum, Woking.
Home, Andrew, M.B., C.M., Inverness District Asylum.
MacLean, Alexander, M.B., C.M., Deputy Surgeon General, Thurso, Caithness.

Stewart, William H., M.B., C.M., H.M.S. *Clyde*, Aberdeen.
Stuart, William, M.B., C.M., Stratton, Cornwall.

Degrees of M.B. and C.M.

†Alcock, Alfred William, Bombay.
Anderson, John, M.A., Marnoch.
Brown, David MacDonald, Banchory-Ternan.
Butchart, Charles Alexander, Aberdeen.
Connan, Alexander Gray, Aberdeen.
Cowan, Andrew Hunter, Aberdeen.
†Davidson, John Stuart, Mauritius.
Deane, E. Greaves Wooding, Barbadoes, West Indies.
Duncan, John, M.A., Aberdeen.
†Godfrey, Henry William, Hornhurch, Essex.
Gunn, James William McKenzie, M.A., Reay, Thurso.
Henderson, Albert Edward, Sheffield.
Irvine, John Charles Davidson, Udny.
†Jones, Francis Grice, Denbigh, North Wales.
*Lamb, John Marshall, M.A., Aberdeen.
Marsden, John, Banff.
*Milne, Alexander, Huntly.
†Milne, James Black, Huntly.
Morgan, William Vincent, Narberth, Pembrokeshire.
†Paterson, Thomas George, New Galloway.
*Rattray, Patrick Whyte, M.A., Aberdeen.
Scott, George, Aberdeen.
Simpson, David, M.A., Alvah, Banff.
Simpson, William Bulmer, Bedale, Yorkshire.
*Smith, Arthur Greatorex, Marlborough.
Sullivan, Peter Alfred, Carlisle.

* Highest Academical Honours. † Honourable Distinction.

The John Murray Medal and Scholarship was awarded to

Patrick Whyte Rattray, M.A.

The following were certified as having passed all the examinations, but did not graduate:—

Charles Mitchell Aird, Leslie Durno, James Murray, Cecil Robertson, and John Hutton Stenhouse.

The next Professional Examination for degrees in Medicine commences on July 18th.

College of Physicians in Ireland.—At the April examinations the following obtained the licences in Medicine and Midwifery of the College:—

Medicine.—Robert Blackwell, Thomas J. Dillon, William Dillon, Andrew A. Doyle, Richard Herbert Joseph Fetherston, James Heffernan, Samuel Horneck, John Lowney, David Charles Morgan Lunt, John McFadden, Joseph Daniel McFeely, Edmond Ryan MacMahon, Septimus Palmer, Paul A. Piel, Joseph Robinson, Herbert Shackleton, Henry Barlow Strong, Hamilton James Thornbury, Richard Henry Tailour, Everard Woods.

Midwifery.—Robert Blackwell, William Dillon, Richard Herbert Joseph Fetherston, David Morgan Lunt, John McFadden, Joseph Daniel McFeely, Paul A. Piel, Joseph Robinson, Hamilton James Thornbury, Everard Woods.

The undermentioned were admitted Fellows:—

A. H. Horne. | F. X. MacCabe.
James Pollock.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 9th inst.:—

Cockerill, John W., St. Bartholomew's Hospital.

Passed on the 16th inst.:—

Carless, Albert, King's College.
Crowdy, F. Demainbray, St. Thomas's Hospital.
Rattray, Alexander, Edinburgh University.
Warner, Frederick Ashton, St. George's Hospital.

We are asked to state that the Press Information Agency is now a Limited Liability Company.

Mr. Joseph Crossland, local banker and manufacturer, has given £1000 to the Huddersfield Infirmary for the establishment of a children's ward.

Thompson Memorial Home, Lisburn.—This institution has just received the very handsome donation of £10,000 from a relative of the late Dr. Thompson.

On the 18th inst., the Kent justices decided to build an infectious diseases hospital at the County Lunatic Asylum at Chartham, near Canterbury. The cost will be £2500, or about £125 per bed.

The Corporation of Cork have passed a vote of thanks to Dr. Donovan for his exertions, in conjunction with his staff of assistants, in grappling with, and stamping out, the epidemic of small-pox in that city.

Epsom College.—The Rev. Dr. West will retire at the end of Easter Term from the Head Mastership of the Medical College at Epsom, which he has held for fifteen years; and the Council have appointed the Rev. W. Cecil Wood, M.A., as his successor. Mr. Wood, who is now Head Master of Birkenhead School, has had much experience in important public schools, and especially at Wellington College, where he was a master for eight years.

Association of Members of the Royal College of Surgeons.—The annual general meeting of this Association will be held on Tuesday, May 5th, at 4 p.m., in the Westminster Town Hall, Dr. Danford Thomas in the chair. All members of the College are invited to attend.

American Precautions against Cholera.—The *Liveprool Journal of Commerce* says that the United States Government is taking early precautions against the introduction of cholera into their country. Orders have been issued by the American Consul at Liverpool that he must have twenty-four hours' notice of the sailing of any vessel to the United States, in order that it may be subject to sanitary inspection by officers specially appointed for that purpose.

Paddington-green Children's Hospital.—The report, which was read at the second annual meeting of the contributors to this hospital on the 16th inst., stated that 288 in-patients had been admitted during the year; 9356 new out-patients were treated, the total attendances being 29,328, or an increase of 10,669 over those of 1883; 398 casualty cases also received attention. The yearly expenditure is about £1700, towards which there is a subscription list of £679. During 1884 a sum total of £258 was subscribed by the working-men of the district.

City of London Truss Society.—The seventy-eighth annual festival in aid of this Society was held on the 21st inst., the Lord Mayor presiding. Since the charity was established in 1807, more than 406,000 patients of all ages and both sexes have been relieved, the number in the first year being 227, and last year 9248. In 1884 the regular annual subscriptions amounted to £1843, new and additional subscriptions to £144, life subscriptions and donations to £902, legacies to £1868, and extra by governors for letters £103. During the evening subscriptions amounting to £520 were announced.

Victoria University.—At a meeting of the Court of this University last week, Professor Rendall moved the following resolution, which was approved:—"That any registered medical practitioner who shall have qualified to practise medicine or surgery prior to January 1st, 1885, shall be permitted to enter for the intermediate and final examinations for the degree of Bachelor of Medicine without having previously passed the entrance examination in arts or the preliminary examination in science, provided that all other requirements for admission to the intermediate and final examination have been duly complied with."

Sanitation at Bedford.—An action was recently brought against the Mayor and Corporation of Bedford for cutting off the connexion between the drains of the plaintiff's houses and the main sewer. The Corporation, in defence, alleged that the plaintiff covered in his drains without notice to their surveyor to afford him an opportunity of inspecting them; that "it is most important in the interests of the public, and is, in fact, absolutely essential for sanitary purposes, that the corporation surveyor should have an opportunity of inspecting the drains of houses and their connexions with the main sewer before they are covered in;" and that the plaintiff was duly required in writing to uncover them for inspection, which he refused to do. Evidence having been given as to the faulty construction of the drains, judgment was given for the defendants.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Bramwell, Hugh Ransom, M.B. & C.M.Ed., has been appointed Resident Physician to the Royal Infirmary, Edinburgh.

Clark, William Thomas Marston, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health to the Twickenham Urban Sanitary District; Surgeon to the Loyal Orleans Lodge of Oddfellows (Manchester Unity); Surgeon to the Waldegrave Lodge of Oddfellows (Manchester Unity); Surgeon to the Boys' Home, Twickenham; Surgeon to the Twickenham Provident Dispensary; and Surgeon to the Twickenham Lying-in Charity.

Crossfield, Arthur Kyffin, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Thirteenth District of the Totnes Union, vice Stone.

Cunningham, Peter Hannah, M.B., C.M.Glas., has been appointed Government Medical Officer for the Shire of Majorca, Victoria.

Griffiths, William Charles, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Conwil Elvet District of the Carmarthen Union, vice Lloyd, resigned.

GUINNESS, THOMAS ARCHIBALD, L.K.Q.C.P.I., M.R.C.S., has been appointed Medical Officer for the Bampton District of the Tiverton Union, vice Nason, resigned.

IRVING, JOHN CHRISTOPHER, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Billinghay District of the Sleaford Union, vice Thompson, resigned.

LLOYD, MORGAN, L.R.C.P.L., M.R.C.S., has been appointed Medical Officer for the Llangendeirne Upper District of the Carmarthen Union, vice Timmins, resigned.

MCHUGH, MICHAEL, M.B.Dub., L.R.C.S.I., has been elected Assistant-Physician to St. Vincent's Hospital, Dublin.

MCKEE, JAMES CHARLES, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Health Officer for the Borough of Raywood, Victoria.

PARRY-JONES, M., M.B., B.S.Lond., M.R.C.S., has been appointed Resident Medical Officer at the City of London Hospital for Diseases of the Chest, Victoria-park, E.

PESKETT, ALFRED F., M.R.C.S., L.S.A.Lond., has been appointed Resident Accoucheur at the London Hospital.

PIKE, JOSEPH BAIN, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Loughborough District and Workhouse, Loughborough Union, vice Palmer, resigned.

SOUTTER, JOHN CLEMENT, M.D., C.M.Aber., has been appointed Government Medical Officer and Vaccinator at Murrumburrah, New South Wales.

STEPHENS, CHARLES, L.R.C.S.Ed., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the Stow Union, vice Ebden, deceased.

STOKES, ALFRED WALKER, F.C.S., has been appointed Public Analyst for St. Luke's Parish, vice Pavy, resigned.

Births, Marriages, and Deaths.

BIRTHS.

CHETWOOD.—On the 16th inst., at King-street, Finsbury-square, the wife of William Chetwood, M.R.C.S., of a son.

GIBSON.—On the 21st inst., at Stanley House, Blackstock-road, Finsbury-park, N., the wife of Dr. J. C. Gibson, of a son.

SMITH.—On the 19th inst., at Christ's Hospital, London, the wife of Alder Smith, M.B., F.R.C.S., of a daughter.

WEATHERHEAD.—On the 30th ult., at Fairview Ranch, Boorne, Texas, the wife of J. F. Weatherhead, M.R.C.S., of a daughter.

MARRIAGES.

BURCHELL—EVANS.—On the 9th inst., at the Parish Church, Aldeburgh-on-Sea, Suffolk, Peter Lodwick Burchell, M.B.Lond., F.R.C.S.Eng., to Emily Anne Frances, widow of T. H. Evans, Esq., second daughter of the late William Webber, F.R.C.S.Eng., and granddaughter of the late Sir Thomas Preston, Bart., of Beeston Hall, Norfolk.

HUNT—BAWTREE.—On the 16th inst., at St. Mary-at-the-Walls, Colchester, by the Rev. Canon Luard, Vicar of Stanstead, Essex (uncle of the bride), assisted by the Rev. J. W. Irvine, Rector and Rural Dean, and the Rev. J. G. Bullock, Rector of St. Nicholas and St. Runwald, Edgar Atlee Hunt, M.R.C.S., L.R.C.P., L.S.A.Lond., of Colchester, eldest son of Josiah Hunt, Esq., of Queen Anne's Gate, Westminster, and Putney, S.W., to Charlotte Mary, third daughter of John Bawtree, Esq., of Colchester.

PENFOLD—BAYNE.—On the 3rd February, at All Saints Church, Sandhurst, Victoria, by the Rev. J. Garlick and the Ven. Archdeacon MacCullagh, Oliver Penfold, M.R.C.S. & L.S.A.Lond., to Mary Louisa, second daughter of Alexander Bayne, Esq., of Montanvert, Sandhurst.

SEQUEIRA—STAFFORD.—On the 9th inst., at the Parish Church, Chiswick, Henry J. Sequeira, M.R.C.S., L.S.A.Lond., eldest son of Henry L. Sequeira, M.R.C.S., of Waltham Lodge, Tulse-hill, and the City, to Inez W. E. Stafford (Nina), only daughter of William J. Stafford, Esq., of Bradmore House, Chiswick, W.

SHORE — SARGENT. — On the 28th inst., at St. Peter's, Regent-square, W.C., by the Rev. R. H. A. Bradley, Vicar, Thomas William Shore, M.B., B.Sc.Lond., M.R.C.S., &c., eldest son of T. W. Shore, Esq., of Southampton, to Mary Elizabeth, eldest daughter of H. E. Sargent, Esq., M.D., M.R.C.S., &c., of Shadwell. No cards.

WARD—LYNCH.—On the 16th inst., at St. Gregory's, Sudbury, Suffolk, by the Rev. T. Lingard Green, Rector of the Parish, assisted by the Rev. H. C. Jollye, of Westmount, Dover (brother-in-law of the bride), Allan Ogier Ward, M.B. & C.M., of Casita, Northumberland-park, Tottenham, to Lelia Catherine, daughter of J. C. Lynch, Esq., M.R.C.S., of Sudbury, Suffolk. No cards.

DEATHS.

HARRISON.—On the 17th inst., at Gipsy-hill, Upper Norwood, S.E., Joseph Harrison, M.D., eldest son of the late Thomas Harrison, of Lotamore, Glanmire, co. Cork, aged 70.

LEEMING.—On the 16th inst., at the Victoria Hotel, Southport, Robert Toulmin Leeming, F.R.C.S.Ed., M.R.C.S., & L.S.A.Lond. (of Kendal), aged 55.

PUDDICOMBE.—On the 17th inst., at Dartmouth, Devon, John Morgan Puddicombe, F.R.C.S., aged 70.

SMITH.—On the 12th inst., at Greenhill, Weymouth, William Johnson Smith, M.D., aged 72.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, April 27.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Althaus: A case of Syphilis of the Brain.—Dr. West: On Hæmaturia in Granular Kidney.—Dr. Herbert Snow: On the Free Use of Caustic Potash in the Treatment of Cancer of the Cervix Uteri.

Tuesday, April 28.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. A. L. Lewis: On the Past and Present Condition of Certain Rude Stone Monuments in Westmoreland.—Rear-Admiral F. S. Tremlett: Quadrilateral Constructions near Carnac.—Mons. Jean L'Heureux: The Kekip-Sesoators or Ancient Sacrificial Stone of the North-West Tribes of Canada.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Doran: Notes on so-called Non-ovarian Dermoid Tumours.—Dr. Hale White: On the Pathological Histology of the Semilunar and Superior Cervical Sympathetic Ganglia. Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

WHAT DEATH-RATE CHARACTERIZES A "PERFECT PARADISE."

A MEMBER of the Romford Local Board considers that locality a "perfect paradise." The reason, apparently, of his enthusiasm is hygienic rather than sentimental. It seems that the Local Board began its existence in 1854 with a death-rate in their district of 28 per 1000. By means of hard work and judicious administration this is now reduced to 15·8 per 1000. Though the Board has certainly something substantial on which to congratulate itself, Dr. Richardson would tell them that the goal of a hygienic paradise was still a long way ahead.

Dr. J. Weaver.—We think it would be premature to notice the matter, as the gentleman in question has not yet, we believe, been formally asked to come forward as a candidate.

G. B. (East Finchley).—We cannot insert the appeal. Perhaps an application to a society such as that in St. George's-road, S.W., might be useful.

"WHOOPING-COUGH."

To the Editor of THE LANCET.

SIR,—In reply to Mr. Burman I beg to state—(1) The paroxysms of whooping-cough are, in my experience, always more frequent at night, whether the patient sleeps or not. (2) I have noticed that they are most frequent about 2 or 3 o'clock in the morning, at which hours the air is most chilly and the temperature of the body lowest. (3) The child awakes from sleep, evidently suffering from a sense of irritation in the throat, and cries at the unconquerable tendency to cough, which it seems to dread; but the more profound the sleep, the less is this tendency. (4) Cold and exposure appear to induce attacks quite as frequently as the act of deglutition.

The treatment of this disagreeable and fatal malady will, of course, depend upon the theory framed as to its exact nature. Though generally induced by direct infection, whooping-cough frequently follows attacks of bronchitis and ordinary catarrh. I regard it as essentially a subacute inflammatory condition of the mucous membrane of the larynx. In its first stages there is no noticeable whoop during inspiration, but simply a short cough. This becomes more prolonged as the disease progresses, until, when the paroxysms are most intense, every particle of air seems to be expired in a rapid series of what might be termed "glottic explosions," and the child, now almost suffocated, again inspires, the air producing a falsetto note by reason of the contraction of the vocalising muscles during the inspiratory effort. The phlegm secreted is at first purely of a mucous nature, but as the disease develops and becomes chronic it assumes a muco-purulent character. The presence of a parasitic organism is, I consider, the result, not the cause, of the disease, and is, I should think, never noticed in its earlier stages, but only when, from the continued inflammatory action, the parts have become prostrated in vital power, and unable in consequence to resist its growth and development in their vicinity.

I have found a popular remedy very efficacious in the treatment of whooping-cough. I refer to picked oakum worn by the patient either round the neck in muslin or on the chest as a pad stitched to the underclothing. *Locally I apply the glycerine of tannic acid with a laryngeal* brush two or three times a day, and internally I prescribe one-, two-, or three-grain doses of chloral, one, two, or three minims of belladonna, one grain of alum, and one minim of carbolic acid, in syrup, every two or three hours. A liniment of turpentine, acetic acid, and yelk of egg is an excellent application for the chest, back, and neck night and morning, with the liniment of belladonna added in the proportion of 1 to 7. In children of two years or more, I have applied carbolic acid and glycerine, in the proportion of 1 to 15, to the larynx with success, each application checking a paroxysm at once. With the above-mentioned treatment I cure the worst cases in from seven to ten days.

I am, Sir, yours truly,

Clayton-le-Moors, April 16th, 1885. C. R. ILLINGWORTH, M.D.Ed.

PROVIDENT DISPENSARIES.

PROVIDENT DISPENSARIES may be very good things; but they may be abused, either by being made available for persons who are not entitled to use them, or by being made the means of indiscriminate advertisement in handbills scattered broadcast. A bill of this kind has been sent us from Cardiff with the names and addresses of ten or twelve medical men.

Mr. J. L. Stretton.—We do not perceive any legitimate ground for interference.

"DISINFECTANTS."

To the Editor of THE LANCET.

SIR,—Your report of the paper recently read by Mr. Wynter Blyth before the Society of Medical Officers of Health on the "Action of Disinfectants on Microzooids" (see THE LANCET, April 4th, 1885, p. 621), will doubtless interest those investigators working in the discovery of bacilli and of germ-destroying agents. The facts connected with the properties of the pyridine bases, as disclosed in the valuable researches of Mr. Wynter Blyth, and referred to in the paper read before the Society, are of considerable import, and fully confirm the views and opinions of previous observers who have studied the compounds named. It may be of interest to state that they may now be obtained commercially in quantity; and that disinfecting powders and fluids containing a proportion of the bases in conjunction with carbolic acid are already in the market. Fluids also containing these substances are in successful use as washes for exterminating scab, acari, and parasites in sheep and other animals. Referring more generally to the pyridine bases, it may be mentioned that in an article appearing in the *Boston Medical and Surgical Journal* for July 14th, 1881, pointing out the high value and utility of certain phenylic washes (used at the Massachusetts General Hospital in the antiseptic treatment of surgical cases) that were found to be practically free from carbolic acid, and concerning which there was some speculation as to the active constituent, it was ultimately found that these compounds were present in sufficient quantity to impart the character observed, and to which Mr. Wynter Blyth now points as bacillus-destroying agents of great potency. From my own knowledge and observation, I would venture to predict a wide rise in the future employment of these basic compounds for the treatment of various skin diseases of parasitic origin, used either in aqueous solution or as pure substances, and would commend them to the notice of medical practitioners for this purpose. Having prepared and supplied the pyridine bases referred to and used by Mr. Wynter Blyth, I shall have much pleasure in furnishing samples to those investigators who may wish to make trial of their specific qualities. I am, Sir, yours faithfully,

BENJAMIN NICKELS, F.C.S., F.I.C.

Leadenhall-street, E.C., April 20th, 1885.

Mr. W. Brown.—The drug should be given with great care. Pregnancy does not absolutely forbid its administration.

Mr. L. Hudson.—Vacancies are announced in our advertising columns.

"MEDICAL PRACTICE IN THE UNITED STATES."

To the Editor of THE LANCET.

SIR,—I presume I, as a graduate of New York, must answer the questions of "Medicus" in your issue of the 11th inst. As a general rule, respectable medical colleges in the United States require the last course of lectures to be taken out, and the passing of a practical examination, before granting an *ad eundem* degree. It does not much matter where the applicant has previously studied, or what qualifications he possesses. I may add, however, that with the qualifications your correspondent holds he would not be debarred from practising in any portion of the States; but he might have difficulty in a legal matter if involved therein. "Medicus" will not, however, find it a matter of so much difficulty as it is in the mother country for a foreign practitioner to carry on his profession; and he may rest assured that if he makes the acquaintance of the authorities in any State where he wishes to reside he will have every courtesy shown him, and every facility given to make him acquainted with anything he may wish to know. There is not that exclusiveness in friendly relations betwixt caste and its privileges *versus* new comers as is generally maintained in old countries.

I am, Sir, yours faithfully,

April 13th, 1885. AN M.D. OF NEW YORK.

CASCARA SAGRADA FOR CONSTIPATION.

To the Editor of THE LANCET.

SIR,—With reference to the subject of the action of cascara sagrada, which has lately been discussed in your columns, I beg to say that for the last two years I have taken it for the relief of habitual constipation arising from sluggish action of the liver, and have found its effects upon myself somewhat different from what your correspondents describe. It has always acted as an efficient hepatic stimulant, as evidenced by the increase of the fæcal colouring matter, but only as a mild intestinal one, and that without producing any pain or griping. I take it uncombined in the form of one-drachm doses of the liquid extract of Messrs. Southall Brothers. In a case of severe constipation in which I lately prescribed it, combined with large doses of tincture of belladonna and nux vomica, it caused considerable griping, and acted most powerfully on the intestines. The preparation dispensed was that of a different firm from the one I myself use.—Yours truly,

April 6th, 1885. T. L. K. DAVIES, M.B.

THE MISCARRIAGE OF MEDICAL EDUCATION.

Dr. Bernard O'Connor.—It is not profitable to cry over spilt milk, or to waste time in debating the question, Who were responsible for the miscarriage of medical legislation last year? Happy are those who feel themselves free from blame! Dr. O'Connor thinks Dr. Farquharson's explanation satisfactory. We do not.

A CASE OF MISSED LABOUR.

To the Editor of THE LANCET.

SIR,—A short description of the following case may be of interest to some of your readers.

On the evening of July 22nd, 1884, I was called to see Mrs. M. T——, a patient who had been expecting her second confinement, when she gave me the following history:—She last menstruated at the end of September or beginning of October, 1883, but was not sure of the time of quickening. The pregnancy was perfectly natural up to the middle of April, 1884, when the movements of the fœtus, which had been well marked, ceased. From this time she did not increase, but rather diminished, in size, and immediately a cold heavy weight was constantly felt in the abdomen, and a discharge, sometimes of blood, sometimes of yellowish slime, began. On the morning of July 22nd, 1884, labour pains commenced, the waters breaking, and a large quantity escaping. She expressed herself as having been in fairly good health up to this time. Her only child was nine years old, the husband having been absent at sea for a long period. On my visit at 10 P.M., I found a healthy-looking Scotch woman, aged thirty-three, not suffering from any labour pains, with the uterus projecting two inches above the umbilicus, and some loose membrane protruding from the os, which was rigid and would only just admit the point of the finger. Her general condition was good.—23rd: Sanguineous discharge all night; uterus level with the umbilicus; os the same size. There was some slight attempt at labour pains.—24th: The uterus and os in the same state; a small piece of membrane was discharged. There were no pains.—25th: Discharge becoming offensive.—26th: Feverish symptoms and rigor; portion of hairy scalp passed; discharge fetid; slight tenderness over the uterus. Up to this date the treatment had consisted of the administration of ergot and antiseptic injections, but the symptoms having become serious I obtained permission to interfere. On the 27th, the patient being under chloroform, I introduced my forefinger through the rigid os and felt the skull, denuded of its scalp, presenting. An attempt was then made to dilate the os with the fingers, but the part was so rigid that an extensive laceration was made. The skull was now taken away piecemeal; finally the remainder of the fœtus was extracted, the entire placenta following, and the uterus was washed out. The fœtus was apparently between the sixth and seventh month. Extensive decomposition had set in, the muscles of the back being bare. All went well with my patient until the third day, when, in spite of constant antiseptic uterine injections, a severe rigor occurred, and a sharp attack of septicæmia followed. Four weeks after this, when almost convalescent, she had a relapse, and for six weeks was very ill with peritonitis. However, in the end, she got the better of her septicæmic symptoms, but was left in a terribly emaciated condition. At the present time she has regained her former weight, looks remarkably well, is able to attend to her domestic duties, and has menstruated regularly three times. There is some erosion of the os consequent on the laceration.

I am, Sir, yours faithfully,

Devonport, April 7th, 1885. W. W. PRYN.

"WORCESTER URBAN DISTRICT."

To the Editor of THE LANCET.

SIR,—In your remarks on the eleventh annual report of the Medical Officer of Health for the City of Worcester you state: "In seeking advice the opinion of the borough analyst has been sought, especially as to whether filtration would secure the inhabitants against 'this great source of danger' (i.e., 'pollution by the germs of disease'), and he has answered, 'If efficiently carried out, I believe it does.'" My opinion has neither been asked nor given. I have merely sent reports giving an opinion which Dr. Strange has quoted in his report, and which certainly do not bear out such a statement. Dr. Strange, in making the remarks you quote, was referring to a question which he asked himself and answered himself in his tenth report. When the Kidderminster sewage pumps broke down, and the typhoid excreta of 300 patients was discharged into our waters, I had very grave apprehensions of what results would follow, and must confess that I was agreeably surprised that the danger was at any rate minimised by the effective condition of our filter beds; but it was an experiment so perilous that I should not like to see it repeated. My report, which to avoid a panic was sent in privately and not for publication, clearly showed what I thought of the danger.

I am, Sir, yours faithfully,

HORACE SWETE, M.D.,

Analyst to the County and City of Worcester.

Worcester, April 11th, 1885.

*** On again reading Dr. Strange's report, we find that the expression of opinion as to what filtration can do is his own, and not Dr. Swete's, whom we failed to identify as the analyst referred to. We were misled by the words in question being quoted in inverted commas in a sentence which in the same way quotes Dr. Swete's opinion as to the benefit of filtration carried out.—ED. L.

EARTH-CLOSETS.

Alpha.—If earth-closets be properly constructed and properly managed, we know of no objection to their use in-doors. The best form of closet to secure is the one manufactured by the Moule's Earth-closet Company, which received the Gold Medal of the International Health Exhibition. Its special feature consists in the very efficient manner in which the dry earth is uniformly distributed over every portion of the excreta in the receptacle. The size of the pail will necessitate frequent emptying, and this is a distinct advantage in the case of an in-door earth-closet. Our correspondent should remember that the earth must be *dry*, and *finely divided* by passage through a sieve, and then, apart from excessive wetness of contents, careful supervision is alone necessary to ensure success.

Justice.—1. Yes.—2. Yes.—3. No; but the presence of another medical practitioner is frequently desirable, as he could be called upon to give confirmatory testimony.

M.D., *Late Assistant*, and *Cedric* have not enclosed their cards.

FALSE TITLES AND THEIR BASE USES.

To the Editor of THE LANCET.

SIR,—We are constantly reading in your Answers to Correspondents that certain titles do not carry the right to the prefix of "Dr." With this I entirely agree. I think it is time, and even necessary, for some protest to be made against the increasing practice of addressing medical men who are not M.D.'s as "Dr." Of course, of the lay public, who do not know better, we cannot complain; but I do protest against medical men themselves addressing others, whom they know are not entitled to the designation, as "Dr." this and "Dr." that, not only in the course of conversation but in correspondence. This practice is even now becoming common with societies composed of medical men; only during the last week two medical associations, obtaining my name I presume from the Directory, wherein I appear as "L.R.C.P. Lond." and "M.R.C.S. Eng.," addressed me as "Dr." To my mind this system of mutual "back-scratching" is bad form, undignified, and unbecoming amongst members of a learned profession, and calculated to bring us into ridicule and contempt.

Allow me to recount a true tale to point a moral. Not many years ago, in the metropolis, there was a post vacant for a medical officer of health. There were many candidates, for it was a good appointment, and amongst them were two special favourites in the betting. The first favourite, having very great influence, was considered bound to win; but he had always been in the habit of calling himself "Dr.," had "Dr." on his door-plate and "Dr." on his visiting card, and naturally by the public was thought to be an M.D. But he was not; he was simply L.R.C.P. Ed. The second favourite was plain "Mr." At the meeting of the vestry for the final settlement of the conditions of election, the principal supporter of the first favourite suddenly hit upon a brilliant idea, as he thought, to oust the second favourite and to secure for his friend the appointment. He therefore proposed and carried that it should be a *sine quâ non* that the future medical officer of health should be M.D. One can imagine the tableau when, on rushing off to tell his friend the clever electioneering trick he had succeeded in, the latter had to confess he was a sham, and not M.D. after all!

I am, Sir, your obedient servant,

April 11th, 1885. ANTI-HUMBUG.

AGORAPHOBIA.

To the Editor of THE LANCET.

SIR,—Can any of your readers suggest a treatment for what I suppose I may call a case of agoraphobia? My patient is a young lady aged twenty-two, with a tendency to constipation and occasional attacks of hæmorrhoids. The first symptoms of a dislike to going out alone showed themselves about two years ago. She was for a long time ashamed to speak of this, and made all kinds of excuses to avoid the necessity of a solitary walk. But now she dare not walk twenty yards alone. If any chance compels her to do so, she feels almost paralysed, unable to stir, and violent palpitation comes on; but if a friend joins her, she can walk actively and for a considerable time, and will appear bright and happy and in apparently perfect health. There is no organic heart disease, and the catamenia are regular. No cause can be assigned for the commencement of the affection. Tonics, such as iron, nux vomica, and arsenic, have been used, also the bromides of potassium and sodium. The family history is good. Any hints as to treatment would be highly acceptable. I am, Sir, yours faithfully,

Bradford, April 18th, 1885. W. HILL EVANS, M.D.

"IMPROVED FRACTURE BOX."

To the Editor of THE LANCET.

SIR,—In your last issue Mr. T. G. Nasmyth says that he has already used a fracture box similar to mine for two years. Permit me to state that I think he does not quite understand the construction of the apparatus for which I claim invention. 1. He does not allude to the sliding reversible splint which forms one of the sides of my fracture box. 2. No one has as yet used a hinged foot-plate with such a regulating screw as I have devised. 3. There is no ratchet, as it would add to the cost. 4. Ferguson has already used perforated splints, but not as I do—as a means of attachment; and to Rhases, an Arab doctor of the twelfth century, belongs the invention of keeping fractures in position by straps.

I am, Sir, your obedient servant,

Middleton Hospital, April 20th, 1885. JAMES J. FOLEY, M.R.C.S.E.

BLOOD-POISONING TREATED BY HYPODERMIC INJECTION OF CARBOLIC ACID.

To the Editor of THE LANCET.

SIR,—I think the following mode of treatment of a not unfrequent and sometimes fatal condition worthy of note.

R. S——, a slim, delicate-looking lad, aged sixteen, received a cut from a knife charged with putrid matter across the palmar aspect of the third and fourth fingers of the left hand. On the morning of the second day after the occurrence the patient felt chilly and generally unwell. On my arrival, a few hours afterwards, I found the lymphatics of the arm inflamed, tenderness of the glands in the axilla, and a temperature of 101·4° F. Nine hours afterwards the patient complained of sickness, with occasional vomiting, and increased pain, with stiffness in the axilla. There were a more diffused redness of the limb and a temperature of 103·8°. I now injected six minims of a 4 per cent. solution of carbolic acid into the unaffected arm. After twelve hours the patient felt better, and the temperature had fallen to 101·8°. The injection was repeated, and no local applications were used. The patient then rapidly recovered, and in twenty-four hours every symptom had disappeared. I am, Sir, your obedient servant,

Wick, April 11th, 1885. A. G. AULD, M.B.

W. T. H.—The lectures on Medical Jurisprudence delivered at any of the medical schools would meet the requirements of our correspondent. He can take out a single course without having entered as a medical student.

T. S. K.—Application might be made to the Hospital in Queen-square, or to the Institution in Portland-terrace, Regent's-park.

Mr. Frederic Hewitt.—The paper is marked for early insertion.

THE TITLE OF "DOCTOR."

To the Editor of THE LANCET.

SIR,—I see the Colleges of Physicians and Surgeons are about to take into their consideration, if they have not already done so, the propriety of allowing the Licentiates of both institutions to take the title of "Doctor." Will they extend their consideration a little further—namely, to the repayment to those who have taken, besides their licences, the degree of "Doctor" at a University, with the expenditure of a considerable amount of inconvenience, time, and money, on account of the higher standing this title, so honourably obtained, was supposed to confer upon them? If they do not do this, I for one must consider I have been mercilessly robbed. It is singular that the outcry of a few who have no right whatever to complain, inasmuch as they have never subjected themselves to these inconveniences, &c., should be able to overthrow and reduce to no value the labours of those who have undergone them all. I am, Sir, yours obediently,

April 22nd, 1885. M.D.

G. P.—We do not understand the question as it is put.

A Medical Student.—We cannot notice the "miserable" print.

ERRATUM.—In our leader on Reform at the College of Surgeons, p. 713, col. 1, line 4 from bottom, "The Board of Examiners" should be "The *Court* of Examiners."

COMMUNICATIONS not noticed in our present number will receive attention in our next.

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris

DICAL DEPART

Clinical Lecture

ON

CONGENITAL TUMOURS.

Delivered at the Manchester Royal Infirmary,

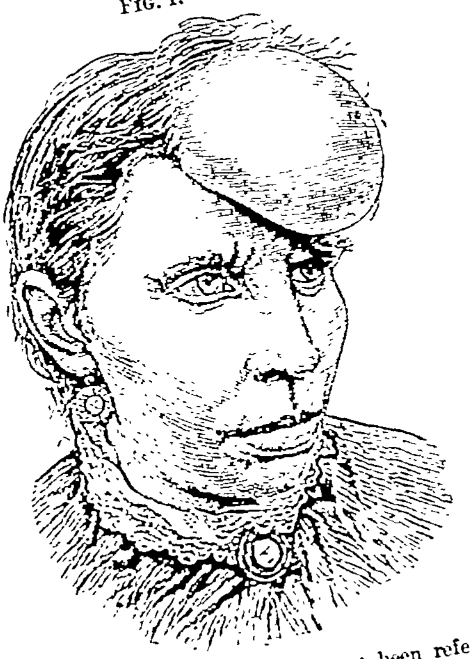
BY JAMES HARDIE, F.R.C.S.,
SURGEON TO THE INFIRMARY, AND LECTURER ON CLINICAL SURGERY AT OWENS COLLEGE.

GENTLEMEN,—Having recently had in my wards several cases of congenital tumour, I propose to take the opportunity which they afford of drawing your attention to a class of cases which cannot be frequently well illustrated in a general hospital. By the term "congenital tumour," I do not mean to include all tumours which may be met with congenitally, nor do I mean to exclude all tumours whose existence is not evident at the time of birth. The cases I refer to are those of tumours which are dependent on and arise from mere developmental errors of the normal tissues. They are associated with the growth of the embryo, and as a matter of fact, have nearly always grown to such a size at the time of birth as to be recognisable at that period, or very shortly after it. The errors of development which produce these tumours may be classified as follows: (1) Included fœtation; (2) dissociated blastoderm (dermoid cysts); (3) tissue hypertrophy (fibro-fatty tumours, cystic tumours, and nævi).

1. *Included fœtation: attached fœtus.*—In the development of the blastodermic vesicle the normal course is the formation of a single embryonic area, and subsequently of a single primitive streak and a single medullary groove. If, however, a double embryonic area be formed, two embryos will result in place of one only; and if these areas come in contact, a fusion of the two, to a greater or less extent, may take place. As a result there will be a double fœtus. The degree of attachment in such a case may vary from a mere band of soft tissue, as in the well-known case of the Siamese twins, to an extensive coalescence and fusion of a part of the skeleton. The latter result is the more likely to occur, according as the duplication supposed takes place at a later period than the appearance of the embryonic area. Instead of being merely "attached" in the manner indicated, the coalescence may be so complete that one of the germs may be surrounded by the advancing development of the other, and its growth seriously compromised. Thus it might occur that a limited portion only of the parasitic fœtus attains full development, and monstrosities of various kinds be thus produced. Projection of one or more limbs of the parasite from the body of the host is an ordinary example of such a monstrosity. It may even happen that at the time of birth the inclusion may be still complete, and the abnormal condition only become manifest by the sprouting forth of the parasitic members at a later period. While these various forms of monstrosity are sufficiently interesting from an embryological point of view, they have very little of surgical interest in them; and I have alluded to them merely to give an aspect of completeness to the subject I am dealing with. We pass on to a class of cases to which the appellation of the term "tumour" is strictly accurate, but whose genesis may still be referable to the same errors of development as have produced the exaggerated condition I have just mentioned—that is to say, to fœtal attachment or inclusion. Closely connected with certain parts of the body, more particularly with the sacrum, the ovary, and the testis, tumours are sometimes met with of a cystic formation, containing a quantity of more or less developed fœtal structures, such as cartilage, bone, viscera, skin, hair, or sebaceous matter. It is probable that here, again, there has been a fusion of the germs of two individuals. It has, however, been more complete than in the former instances, and, from certain causes operating at a very early period, probably from the cutting off of its proper blood-supply, the due development of the included fœtus has been arrested. It thus comes to be dependent for its nourishment on the blood-supply of that part of the host to which it is more particularly attached. As this would generally be provided by vessels of insignificant size, the quantity [illegible] will be too niggardly to permit of more than a very tardy and incomplete growth of the aberrant structures. If I except, possibly, one or two ovarian tumours, I cannot refer you to any example of this class of tumour in my own practice; but I remember very well the case of a young woman who was under the care of Professor Lund in this infirmary, and who had what, I believe, was such a tumour, situated between the sacrum and rectum. In such cases the question of operative treatment will frequently arise, and it will depend largely on the extent of the dissection required to extirpate the growth.

2. *Dissociated blastoderm.*—I have said that the foregoing cases are probably due to the inclusion of a second fœtus. The implied reservation has reference to the mode of origin of the next class of congenital tumours which I have to mention. We have seen how the germ of one fœtus may be enveloped in that of another, and cut off entirely from its proper connexion with the maternal structures. It becomes displaced and detached. In a similar manner you can understand how, in the process of evolution and growth of the layers of the blastoderm of a single fœtus, there may be an inclusion and separation from its proper connexions of some portion of one or other of the three layers. I shall speak to you immediately of cases of tumour which, by common consent, are explained in this way; but it is possible enough that some of those which I have just been referring to, which contain fœtal elements of various kinds, may, in reality, have been produced by some dislocation of the blastoderm of the subject, and not by fœtal inclusion. Probably one would determine the matter by the degree of variety of the contents of the tumour in question. The cases which appear undoubtedly to arise in the former manner are those whose contents consist simply of structures belonging to the skin and its appurtenances. Such tumours are of comparatively frequent occurrence, and are denominated dermoid cysts. They are met with most frequently in the ovary, under the roof of the orbit, in the neck, and on the head. They are to be regarded as due to a displaced piece of epiblast, which, slowly growing according to its original character, in its foreign soil, presents in process of time an epidermal sac with included sebaceous matter, hair, teeth, or, it may be bone, according to the situation to which it primarily belonged. A good example of such a tumour you saw lately in my female ward. Mrs. ——, aged thirty-eight, had a tumour over the middle of the forehead. (Fig. 1.) At birth it was about the size of a marble, and it had gradually increased to be larger than a fist. Situated where it was, there appears to have once been a suspicion that it might be an encephalocele, and operation was not advised. At the time we saw the patient

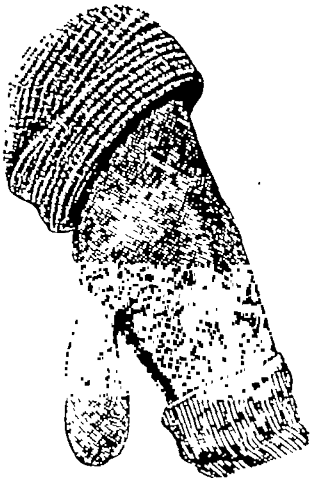
FIG. 1.



however, we were at once satisfied of its real character by the peculiar feeling it had when taken between the fingers. It was easily compressible, and felt somewhat like a bladder of half-melted tallow. For some distance around the most prominent part the skin was closely adherent to the tumour; elsewhere it was separated by cellular tissue. I exposed the growth by a crucial incision, taking care to include a considerable portion of skin, for the reason that this structure in such a case is not simply stretched over the surface, but actually redundant. The dissection was easily accomplished, and the tumour removed from a saucer-like depression in the frontal bone. At one small spot there seemed to be complete perforation of the bone. The tumour consisted of a thin cyst-wall, containing sebaceous matter in various stages of softening and numbers of long fine hairs. You see from the appearance of the patient to-day that the wound healed with a scarcely perceptible scar. All such cases occurring on the surface of the body are readily removable by excision.

3. *Tissue hypertrophy.*—At almost any period of life there may be a tumour formation from a simple overgrowth of some texture or organ, as in the case of fatty tumours or of adenoma of the mamma; but in the fœtus, in which the process of growth is so exceedingly active, there would appear to be a peculiar tendency to such an accident on the part of certain tissues, in consequence of which we have the formation of certain tumours almost peculiar to this period. Occasionally there is met with a congenital hypertrophy of the whole of the structures of a limb or other part of the body; but the tissue which is more especially prone to this excessive development is the ordinary connective tissue, with its contained fat. To a less extent the skin may be similarly affected, and in another class of cases the cutaneous and subcutaneous bloodvessels. In an individual case there may be hypertrophy of all of these tissues, but it is usually most pronounced in one or other, and different varieties of tumour due to this cause are accordingly recognised.

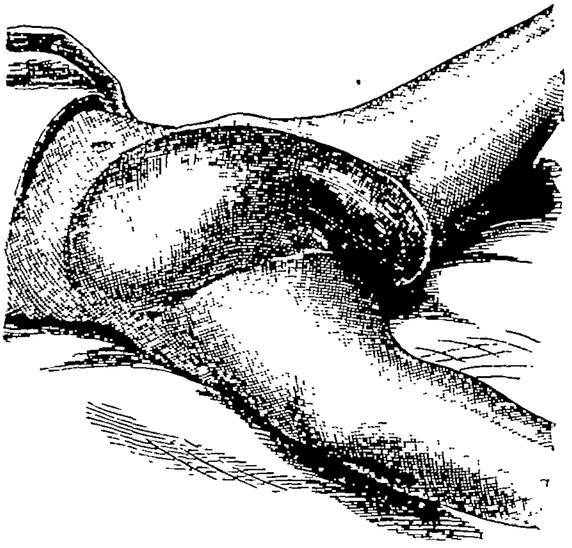
FIG. 2.



I show you here (Fig. 2) the photograph of a congenital tumour hanging from the back of the leg of a man aged thirty-two, who was a patient here some time ago. At birth, it would appear, it was quite small; but as he advanced in life the tumour steadily increased in size, until it measured five inches in length by three in width at the time he presented himself to have it removed. It was attached to the leg by a flattened pedicle about an inch in diameter, and evidently had no connexion with the deep structures. It was uniformly firm in consistence, but not so dense as a fibrous tumour. The skin which covered it was coarser in texture than that in the neighbourhood—a circumstance which may have been an original character of the growth, or which may have been occasioned by the repeated inflammatory attacks to which it was subject by the friction of his clothing. It was on account of this frequent accident that the patient at length determined to have it removed. This was accomplished easily enough. The tumour was found to be an outgrowth of the subcutaneous connective tissue, and on section it presented the appearance of coarse bands of fibrous tissue, with loculi containing fat. Such tumours or hypertrophies are not always so easily dealt with. They are not always pedunculated, but sometimes form ill-defined projections from the surface with wart-like hypertrophy of the skin. At other times the condition met with is an overgrowth of the whole of the skin and cellular tissue investing the distal portion of a limb, as the foot or hand, or one or more fingers or toes. In some cases the fatty, in others the fibrous, tissue predominates; and occasionally there are small cyst-like interspaces containing clear fluid.

This last condition leads us on to the next variety of tumour which I have to mention to you—viz., the congenital cystic tumour. In the previous case the occurrence of cysts is a rare event, and is to be regarded as merely accidental and of little importance. In the case of the tumour I am now speaking of, however, the cystic formation is the essential feature. Of all parts of the body, it is most frequently met with in the neck, and, although also occurring in other parts of the trunk, has never, according to Mr. T. Smith, been met with in the limbs. This tumour has its origin in the connective tissue under the deep fascia. It can usually be ascertained to be intimately connected with some portion of the deep fascia; but as it grows it forms a well-defined tumour separated from the surrounding structures by cellular tissue. It consists partly of solid and partly of cystic tissue, and there is every variety in the proportion of the two constituent parts. In the neck, it is sometimes met with as a single dense walled cyst containing thin straw-coloured fluid, which some people call a hygroma. Some time ago there was such a case under my care here, in a young man aged eighteen. The tumour was the size of a duck's egg, and was situated in the posterior triangle. I dissected it out and the case did well. It is better to treat them thus than to annoy your patient and yourself with setons, injections, and so forth.

FIG. 3.

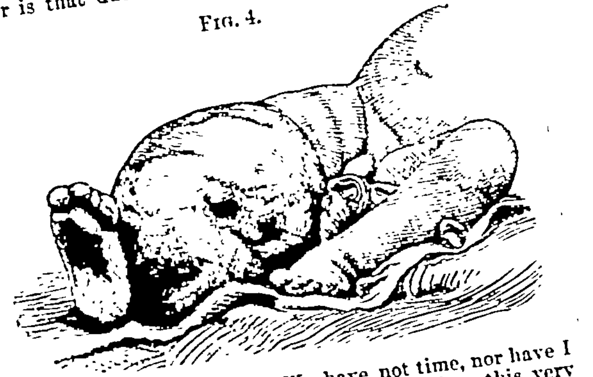


In other cases the cysts are multiple, and for the most part intercommunicate. The case of L. L——, a girl aged six years, sent to me by Dr. Cran, and whom some of you saw, was a good example of such a case. There was a tumour lying in the right groin, extending from the anterior superior spinous process into the labium. It was evidently attached to the abdominal wall, though it had turned over and had obscured Poupart's ligament. There was not much doubt as to its nature, particularly when regard was had to the fact of its being a congenital tumour. At birth it was about a fourth of the size, and it was still growing when the patient came under observation. In the upper part of the thigh, quite separate from this tumour, there was a second swelling about the size of a hen's egg. It was soft, projected but little above the surface, and had no very distinct outline. The parents knew nothing of this second growth, and in the absence of any history I came to the conclusion that it was probably a self-cured nævus. (Fig. 3). I treated this case by making a single incision over its entire length and dissecting it out. Its most intimate attachment was to the aponeurosis of the external oblique, more particularly to that part of it which forms the external pillar of the inguinal canal. To this it was so closely adherent as to appear to have grown from it. Elsewhere its connexions were loosely cellular. The second tumour was not interfered with, nor do I think that it will ever require interference, as it appears to have diminished somewhat in size since the time when the child was in the hospital. I show you the tumour, and, as you will perceive, it is composed of a number of intercommunicating cysts of various sizes, from a hen's egg to a pea, with dense fibrous septa; they contained amber-coloured fluid.

Here is another such tumour which I removed from the front of the neck of a child five months old. It is the size of a large orange, and was growing so rapidly as to be placing the child's life in imminent peril. It had pushed itself under the edges of both sterno-mastoids, and had very close attachments to the surrounding parts, so that its extirpation was difficult and tedious. Happily, however, this was at length accomplished, and its removal gave new life to the child, who soon became quite chubby. You see that the section of this tumour closely corresponds with that of the other, except that the cysts are smaller and more numerous, and that the septa are thicker and in places of gristly consistence. The usual explanation given of the formation of the cysts in this form of tumour is that they are due to an expansion of the normal lymph spaces in the cellular tissue. I cannot say that this explanation is very satisfactory to my own mind; I cannot, however, suggest a better; and if this be the correct pathological explanation, it certainly stamps these congenital growths with a peculiar individuality.

The last variety of congenital tumour to which I have to refer is that due to an overgrowth of vascular tissue.

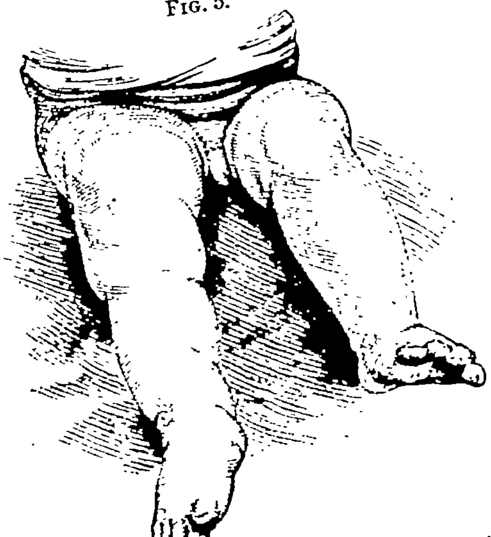
FIG. 4.



This is the familiar nævus. We have not time, nor have I the wish, to enter at present at any length into this very extensive subject, either as regards its pathology or its treatment. You must, however, regard nævus as due to this same peculiarity of certain tissues, in the fœtal condition, to take on an abnormal development, to which I have been referring. Nævi occur with by far the greatest frequency in the skin, or in the subcutaneous cellular tissue. They are occasionally met with in bone and in glandular structures. In some examples the capillary system is probably that in which the affection has its origin, but coincident with this there also occurs an overgrowth of the efferent vessels. There is a multiplication and dilatation of both sets of vessels, while the basis tissue is reduced to very small dimensions. In other cases the capillaries are of normal size, while there is a varicose dilatation of the venules, which push aside the intervening tissue so as to produce a well-defined tumour of turgid vessels embedded in the surrounding parts. When the growth is excised it presents a shrunken trabecular structure. Sometimes this affection causes a more florid colour of the skin, which may be but slightly elevated. At other times the subcutaneous tissue is also more or less involved, and in a third variety the affection is situated in the subcutaneous vessels exclusively, producing a more or less prominent subcutaneous tumour.

I will illustrate this variety of congenital tumour by referring to an important case which came under my care some time ago. This nævus was certainly one of the largest and most formidable which has ever been met with, as you may judge from the photograph which I pass round. (Fig. 4.) It was also of much interest from the successful issue of the very simple method of treatment which I adopted. As you see, the tumour involved the whole of the leg from the knee to the ankle for two-thirds of its circumference. The child was brought to me when only a fortnight old, and when the part was uncovered, its aspect was certainly alarming. The circumference of the affected leg was nearly three times that of the other. The surface was of a bright-red colour, and the skin was in some places so thin that it appeared as if rupture might take place at any moment. The tumour was growing with great rapidity. I feared that amputation of the limb was the only resource open to me; but observing how materially I could diminish the size of the growth by grasping it firmly in my hand, it occurred to me that something might be effected by means of continuous pressure. To this end I bandaged it carefully with elastic webbing, trusting that by compressing the vascular network and at the same time inducing a certain amount of inflammatory effusion into its basis structure, permanent obliteration of the vessels might be produced. This treatment was entirely successful. I was anxious that I should not cause ulceration of the surface, and therefore reapplied the bandage, with but moderate tightness, daily for a few times; but on taking it off, even on the second day, the delicate cutaneous envelope gave way in numerous places, with the immediate result, of course, of an outburst of blood—a very serious matter in so young a child. The part was instantly grasped, however, and the bandage reapplied. After a few days I had the satisfaction of finding the growth becoming solidified and diminishing rapidly in size. In a fortnight's time, I may say, the nævus was non-existent. This photograph shows the appearance of the part some weeks later. (Fig. 5.) Of course this was an altogether exceptional example of nævus. The treatment also was not such as you will very often be able to adopt. But it is a case you will do well to remember. Bear in mind, especially, when you enter upon practice, the exceeding usefulness of pressure as a therapeutic means, for it is in a great variety of circumstances of the greatest usefulness, while it is too apt to be forgotten altogether. I will spare you the recounting of other methods of treating nævus.

FIG. 5.



In addition to these various forms of tumour, peculiar to the fœtal stage of existence, you must bear in mind that almost any other variety of tumour such as we are accustomed to meet with in later life, may also occur congenitally. It is true that such tumours are rare in the fœtus, but there is no intrinsic reason why they may not be found in this association. With these, however, we have at present no concern.

G. A. PILKINGTON, M.R.C.S., L.S.A., Mayor of Southport, has been unanimously elected Liberal candidate for the Southport division by the Executive Committee of the Liberal Association.

ON THE
SPECIFIC ORIGIN OF GENERAL DISEASE.[1]

By J. WALLACE ANDERSON, M.D.,
LECTURER ON MEDICINE, GLASGOW ROYAL INFIRMARY MEDICAL SCHOOL,
ASSISTANT-PHYSICIAN TO THE ROYAL INFIRMARY.

I NEED offer no apology for the subject of the present paper. At the present day it is suggestive enough. At once a whole host of microbes, spores, and other horrid things rise up before us, for in this age there are germs, germs everywhere. They try to win our toleration, if not our sympathy, under the thin garb of a new name; bacilli possibly, little walking-sticks, they call themselves, with quite a wont-you-have-me kind of air. But I am not going to take up the matter lightly. It is a burning question, and one of the greatest interest; the relation between these organisms and disease; and apart from the practical results that may yet follow the subject is not without its attractions as a mere speculative inquiry. It has been left too much in the hands of the pathologists. Surgery has within well-defined limits studied the question, and with an advantage to suffering humanity that few, if any, will gainsay; but when from the wide domain of medicine individual diseases are brought in, and we are told that this and that germ is the only true *fons et origo mali* of each, we may with reason both wonder and doubt. I would still leave to the pathologists the task—a most agreeable one doubtless—of further germ discoveries, believing that there are other views of the question that should readily invite the attention of the medical practitioner. What I have proposed to myself is an abstract inquiry into the essential cause of individual diseases, and what I wish to present to you is the reasonableness of the opinion that many—we can never say how many—diseases are caused by distinct specific germs. Holding this view implies the existence of an opposing force. Now, without going into the old scholastic inquiry as to the nature of health and disease, I suppose it will be admitted that their relation is one of antagonism. Certainly we do act as if we were engaged in a conflict. We endeavour to strengthen the vital forces. We do this by such means as improved sanitary conditions, better food, tonic medicines, or change of air; by keeping up the supplies, so to speak. Again, we do the opposite to the opposing forces. We cut off their supplies by improved hygienic measures: pure air frequently, if possible continually, renewed; attention to cleanliness in all respects. That cuts off the supplies of the invaders. If universally carried out it would lead to the complete extinction of typhus fever, for example. We even go further, and take a lesson from actual warfare by laying waste the fields over which we believe the enemy will march. Do we not do this? do we not willingly submit to the lesser evil, in the expectation of avoiding the greater, when by vaccination we substitute cow-pox for the dangerous and disfiguring small-pox? Practically, then, we act as if we were face to face with foes. But I have often thought that it is on the most general grounds reasonable to suppose that the condition of health is constantly assailed by influences around us. I think we may very properly hold the view that every disease is but a response to an impression of some kind. This law of response seems to be universal in nature. Every act, circumstance, or condition has its response, physical, and, in the case of sentient beings, intellectual as well. It was while reflecting on the nature of fever and its relation to these organisms of contagion, the existence of which I am assuming, that my thoughts went first in this direction. It seemed to me that fever might be viewed as a form of resistance or defence (as a response to an evil necessarily is) against these pernicious influences around us—just as truly as that, in the world of feeling, the flushed countenance, the passion, and it may be the knock-down blow, are the response to the imputation of falsehood. So far as we can judge, this principle is universal, or, as Emerson says, "The law at the foundation of all things is retribution." It will thus be seen from what standpoint I wish to view the origin of disease in this paper. Jonathan Hutchinson, in his lectures on "The Pedigree of Disease," approaches the question from the other side. He dwells on temperament, idiosyncrasy, and diathesis as causes of disease. He does not of course exclude external influences, but holds, or at least inclines to, the opinion that intrinsic conditions rather than extrinsic influences are the determining causes of the endless variety of diseases. But there are two sides to every question, and it is the other I would venture to take and present on this occasion. I am on the side of the germs. My creed is: "The law at the foundation of all things is retribution."

In proceeding further to the consideration of the precise question before us—viz., a specific organism the cause of disease,—I am confronted with the proverbial difficulty of knowing where to draw the line. One has little difficulty with the common infectious fevers, yet many will raise doubts regarding the specific origin of erysipelas and diphtheria; and what shall we say of such diseases as pneumonia, still more of ordinary catarrh? That is where the doubts and the discussion come in. Let us begin with what is pretty well assured—the dependence of each of the common fevers on a specific organised germ. That they are caused by an organism, and not mere inorganic particles, is inferred from the general character of the fevers themselves. They have an incubation, a growth, a maturity, a power of reproduction, a struggle for existence doubtless, a decline and death—the attributes of all living beings. Then it is a matter of common remark that a particular fever reproduces itself and no other. The distinctive characters of each are always preserved. The typhus germ strikes suddenly and vigorously, living on the system as a whole and on no individual part; its death is sudden and on a fairly definite day, and then the sufferer is safe. How different is the germ of enteric fever! Unlike that of typhus, in its immature or larval condition, it is an amphibious creature, most likely taking to the air occasionally, but preferring water, or perhaps rather milk, when it can get it. I say larval state, because from analogy we may infer that it reaches the mature condition in the human body. Once there, it lives longer than the typhus germ, having had a distinctly longer incubation and slower adolescence than its altogether shorter-lived typhus brother. It has its peculiar well-defined local manifestation, and often exhibits that indication of a relapse which is perfected in some of the other fevers. In all these respects it is specifically distinguished from typhus fever. But however interesting the study of the distinctive characters of the common fevers may be, and I think nothing to the physician can be of greater interest, I need not here dwell upon them merely as a proof of what is generally accepted, even were it only accepted truisms I had to offer. I would only ask to be allowed to make an exception in favour of intermittent fever and erysipelas. The ague germ presents some interesting peculiarities. It is essentially an aquatic bird, for though a warm atmosphere invites it, it will not fly far from its home in the marsh. In its fondness for the water it resembles enteric fever, but, unlike the latter, it is in no sense cosmopolitan. But it would seem as if it had another distinctive peculiarity—viz., its size and weight. A belt of trees will catch the germs in its meshes and save the troops beyond, and they are substantial enough to be carried a considerable though still quite limited distance by the wind. Their greater weight may be inferred from the fact that a pretty high temperature is needed to raise their ponderous bodies from their bed, and in no case are they raised to any great height. They have a curious but perhaps not absolutely peculiar affinity for water, as a running stream between is known to be something of a protection to a body of troops on the further side. In all respects the germ presents the most marked contrast to such a one as that of epidemic influenza, which asserts its powers at long intervals, is often pandemic when it does appear, and would seem to be transmissible unimpaired for many miles at least, and solely through the air. Such are some of the best examples I can think of in evidence of specificity.

Now as to erysipelas. I select it as a distinct departure from a class of diseases whose specificity is pretty generally accepted. Perhaps regarding no disease has the question of specificity been more disputed than that of erysipelas, but I do not refer to it to enter upon an enumeration of its special characters, though the subject might be made as interesting as it is ample enough, but rather to call attention to the arguments usually adduced in favour of its non-specificity, because, so far from being conclusive, they rather disclose further the question under consideration. "The arguments in favour of its being a non-specific and local disease," says Bristowe, who summarises them conveniently for us, "are chiefly the following:—First, the fact that the disease appears in many cases to arise from exposure to cold and various other non-specific causes; second, that a previous attack so far from precluding subsequent attacks, as is generally the case with the infectious fevers, encourages them, as is the common rule with the non-specific inflammations; third, that contagiousness is not an attribute of the specific fevers only, for many varieties of simple inflammation (catarrh, ophthalmia, and the like) are apt to spread by contagion."[2] Now the first argument, while qualified by the word "appears," yet to that extent begs the question, for we hold that exposure to cold in the case of erysipelas, as in many other diseases, simply permits the common but still specific germ to gain for the time the mastery over our system. Dr. Francis Henderson is the only one, so far as I know, who boldly advocates that view on abstract grounds. In an able paper on the Rationale of Cold as a Cause of Disease,[3] he maintains the following proposition: "Cold is not of itself adequate to cause these various forms of disease; it is only one of two factors which in ordinary circumstances require to act conjointly. The catarrh, the inflammation, and the fever which are produced by exposure to cold have a real *materies morbi;* but this *materies* could not be the cause of disease if the vital powers of the part or of the system were not abstracted or lowered by the agency of cold." That is the view we have always held. Now, the germ of erysipelas seems to resemble that of ordinary catarrh in respect of its being a very common one, yet acting in its own special ways—amongst others, in taking effect on our system, as some suppose, only through an abraded surface, however minute. As to the second argument, the fact of a disease being taken possibly, or even readily, a second time, is little evidence of its non-specificity. Relapsing fever is a typically specific affection, and one attack is no protection against another. So with regard to intermittent fever; and Maclagan would instance acute rheumatism as another common exception. Then as to contagiousness not being an attribute of the specific fevers alone, we simply say it is an attribute of specific diseases alone, for it need not be a fever, and catarrh is one of the commonest illustrations of this. It may be thought I am hurrying past many difficulties, but these will come up again under the heading of objections.

---

[1] Read before the Glasgow Medico-Chirurgical Society.

But now we come to the difficulty of knowing where to draw the line. What can we say of such diseases as pneumonia, asthma, dysentery, or any other malady taken at random?—although these I have really selected, as we shall see immediately. It is with such diseases that the real difficulty begins in our present state of knowledge, and all that we can hope to do is possibly to suggest some points for further reflection. Well, I think we sometimes create a difficulty by forgetting that symptoms which present a general similarity may indicate very different diseases. We can imagine an ignorant person including an eczema, an erysipelas, and a slight burn under the term inflammation of the skin, or grouping together as one disease enteric fever, dysentery, and simple diarrhœa; and we can suppose a much less ignorant person considering a bronchial spasm due to bronchitis to be the same thing as pure idiopathic asthma; and so on. If it be not admitted that either bronchitis or bronchial spasm is due to a specific cause, and I do not say so myself, it will be allowed that the very same symptom, the asthma, may in some people be the result of a specific factor—e.g., the pollen of hay. Those who believe that there is such a thing as hay asthma will admit that it is a specific complaint. It seems to me, indeed, that the term asthma is as comprehensive and as vague as that of dropsy. And may it not be as vain to ask if pneumonia is a specific affection? May there not be really different diseases included under that term, some specific and others non-specific? Some think a fractured rib can cause a pneumonia. Can that possibly be the same disease as ordinary idiopathic pneumonia, or still more the exceptional epidemic forms? Just as one would expect, the report on pneumonia recently issued by the Investigation Committee of the British Medical Association shows that some kind of division of this term is necessary if we are to make anything of it at all. Without passing any opinion on the classification given by that committee, it seems clear enough from their report that, besides certain forms of pneumonia which are apparently set up by various non-specific influences, there are others of a strictly epidemic character, falling on a district and spreading thence so widely and so inexplicably as to imply a generally prevailing yet special cause. Examples, too, are given which appear to prove conclusively the infectious nature of certain forms. And so with regard to dysentery. Many cases presenting symptoms which lead us to diagnose that disease may no doubt be the result of non-specific causes; but I think few can doubt that the epidemic form handed down through ages with a constant history, and of such exceptional severity, must be the result of a fixed specific cause.

Further than this I shall not attempt to go. We have, indeed, touched but the border-land of disease as a whole in regard to specificity; but beyond we could only wander in vain imaginings. But, possibly, not the least interesting part of the question lies in the consideration of the objections that may be urged against even the position I have now taken. And this will form the second and shorter part of our subject. In the first place, it may be said that the infecting particles of even a specific fever are not organisms at all; it may be held that they are inorganic. I need not dwell upon this objection; for I find that Maclagan many years ago discussed this point very elaborately in his work on "The Germ Theory of Disease." After all, the one essential distinction is that a number of living germs merely sufficient for successful development is all that is needed to secure the maximum effect; whereas the effect of inorganic or lifeless particles is always commensurate with their numbers or amount. The power of infection, too, as distinguished from contagion, is, I should imagine, the prerogative of a living germ; but that may be disputed; the former cannot be, and its bearing on our subject is obvious. Inorganic particles cannot, properly speaking, have an incubation; they do not mature, nor can they reproduce their kind.

To return to the question of specificity. Though we do not venture to affirm that this and that disease are of specific origin, it may occur to some of us that very many diseases are so. We find that not only is ordinary catarrh epidemic and infectious, but in particular seasons we have special varieties of it—say in the form chiefly of a myalgia. Now, one may ask himself if such special forms may not depend on a special form of the catarrhal germ? The supposition is fantastic enough, but I make it for that very reason. It forces us to ask if we are to suppose a germ for everything—for a kick on the shins, perhaps. Simply letting the last remark pass, I would say, first of all, that the specificity of practically an endless number of diseases is not to be considered unlikely on the ground of the limited resources of nature. The variety that nature presents in the visible world is endless, and everything tends to show that the same variety obtains in what is, to our unaided eye, the unseen world. No doubt one instinctively refuses to believe that there is a germ for diphtheria, and for erysipelas, and for pneumonia, and at first may think it simply ludicrous to imagine that common catarrh can depend on a specific germ. It is too quixotic to suppose we are fighting daily with germs and microbes—not indeed by the day, but at every turn we take and every breath we breathe. But I say we are not to consider the position untenable from any limit to variety in nature. Is it not practically infinite? The variety in the vegetable kingdom strikes the dullest, and the learned can divide and classify into groups innumerable the vast array of form and kind; but the work is never done. In moss, and heath, and fern, and such-like meaner things for so we reckon them who know little of them the earnest student finds a continual feast; and amongst the lichens, that almost look like a part of the rock from which they seem to draw their scanty store of life, there are curious secrets hidden, of which even a Leighton or a Stirton has never dreamed. Well, then, one may admit the possibility of a more substantive disease having a specific origin, but refuse to believe that such a vulgar thing as common cold can lay claim to any kind of descent. But is the contrast greater or nearly so great as many which we find in the visible world? Is the contrast between common catarrh and cerebro-spinal fever greater than between the grass that clothes our fields or the weeds that infest our path, and that rare fern that is only found in one shady glen, or the lichen that still lingers, the last of its race, on but one mountain side? It is not half so great. Catarrh is the common chickweed; cerebro-spinal fever the rarer plant that we only meet with now and then. Common plants will grow anywhere—that is why they are common; but rarer plants are of special soils. Anyone will take a common cold, but special cultivation, so to speak, is needed to make anyone take an erysipelas, though in the few it will grow apace. This reference to special soils reminds us of the undoubted fact that some are much more prone to the contagious fevers than others. Occasionally we meet with a person who has had scarlet fever repeatedly, and this exceptional liability we sometimes find is not an individual peculiarity merely, but one that may affect a whole family. I am as firmly convinced, on the other hand, that other individuals and other families present a specially unfavourable nidus for the development of a particular germ. And here too the question of heredity might be discussed, were it not quite understood now that by that expression one only means, where an external morbific influence can be assumed at all, an inherited peculiarity of constitution that is specially favourable to a particular spore. And, lastly, I can suppose this objection still urged: In the natural world there are doubtless many rare plants and animals too, as well as those which are very common; but they all exist somewhere. They do not disappear and return every other year or half century perhaps, as some epidemic diseases do. Or, without looking for analogies at all, one may say, "I will not believe that a malady like true epidemic influenza, which we only see a few times in a century, arises under the same conditions as those diseases which are always with us; it is absurd to suppose that these varied diseases we have been considering originate under one common law." Well, I am not going to prove that the germ of true epidemic influenza or of relapsing fever is always about us, but in an immature state. I do not think we shall get much further in that direction than did Sydenham, when by "epidemic constitution" he meant or supposed a peculiar atmospheric state by which such exacerbations of disease were brought about. But I think we have analogous excesses in the visible world. Those of us who have lived in the country have observed how special years have been marked by special flowering seasons; when the apple-blossom decked every garden, or the primrose covered every grove and meadow. One year the poor man gets his potato cheaper; another will make the rich man pay willingly for the finer wine. In the animal world we have special years of migratory visitants which defy the naturalist to explain. One may see in all this the law of variation which is universal in nature, but we cannot explain the phenomena themselves. I do not think such reflections are idle. They have made me cease to wonder at such an occurrence as a sporadic case of enteric fever. I am no believer in its spontaneous origin. Its germs are likely ever present, but either themselves immature or waiting for a convenient pabulum. And once a centre formed, the extension is a matter of no difficulty. But I must not be tempted to go beyond our present subject. The origin of disease has many sides, and I have only presented one in this paper. It has long been a hobby of mine, and took its origin certainly quite apart from the germ discoveries in medical disease of the last year or two. Of these bodies which the pathologist shows us I know nothing. One may be a whole cityful of germs, or no germ at all. Other views of the question seem to me to have been too much neglected, and one of these I have done my best to offer in the foregoing remarks.

FURTHER OBSERVATIONS ON THE CURE OF WRITER'S CRAMP.

BY A. DE WATTEVILLE, M.A., M.D., B.Sc.,
PHYSICIAN IN CHARGE OF THE ELECTRO-THERAPEUTICAL DEPARTMENT, ST. MARY'S HOSPITAL.

THERE are two phases in the early history of every scientific discovery or new application of practical methods. Its truth or value is at first denied; then, jealousy springing up, the originality of the discovery or invention is placed to the credit of others. When a principle only is involved, the claim is sometimes made for the dead; at other times, however, especially when practical issues are bound up with the question, the attempt is made for the benefit of the living. I had the opportunity a short time ago[1] of describing the remarkable results obtained by Mr. Wolff, of 19, Upper Berkeley-street, London, in the treatment of writer's cramp by a combined application of massage, gymnastics, and caligraphic exercises. The same occurrence which had signalised his first appearance in Germany some years ago saluted his introduction to the profession in this country. It was asserted that his method contained nothing new, that massage was known to the Greeks, and that Swedish gymnastics are as old as the century. Now I did not claim for Mr. Wolff anything but that he alone, among those who devoted themselves to the treatment of writer's cramp, had been generally, nay, almost regularly, successful in his endeavours. I have in vain looked through literature for similar results; and I am glad to find that in the last works which the medical press has given us on mechanico-therapeutics[2] the authors refer to the subject in terms which fully confirm these conclusions. In order to illustrate the value of Mr. Wolff's method I publish two cases, which will speak for themselves. No commentary is needed in presence of facts so clear and so telling.

CASE 1.—Mr. G. H——, a merchant of Liverpool, with no noteworthy family history or personal antecedents, noticed seventeen years ago a weakness in the thumb, index and middle fingers, and a tendency of the arm to turn inwards, when he was writing. These symptoms steadily grew worse up to 1874, when pains began to be experienced, extending from the wrist to the elbow along the ulnar side of the arm. He persisted in his attempts to write, however, and these brought on spasmodic movements and pains in the upper arm, whilst, strange to say, the motor and sensory troubles in the arm and wrist rather showed a tendency to mitigation, being then replaced by tremors. For the last four years the use of the pen has been practically impossible, and the patient exclusively used the type-writer for his correspondence. The use of this instrument rather increased the tremors when attempts were made to write, whilst it developed sensations of pain in the fingers. I first saw Mr. G. H—— in 1883, and again on the 16th of January, 1885, when he came to London at my instance, to place himself in the hands of Mr. Wolff. Several specimens of his handwriting were taken. (See facsimiles.) It took him seven minutes to trace four or five very short lines of very shaky characters. The facsimile bearing the date Jan. 16th was taken just before the first manipulation; the others will tell their own tale. The improvement was steady, and on the 30th of the same month (January) he left London to return to his business in Liverpool. He was then able to write without difficulty for several hours a day. I need hardly say that the ordinary resources of therapeutics, including a rest of several months on board ship, had been in vain resorted to before recourse had been had to Mr. Wolff's method. In fact, so despondent was the patient as to the possibility of a cure, that I had no small difficulty in persuading him to make another attempt to obtain relief from his apparently hopeless malady.

CASE 2.—Mrs. C. K—— came to Mr. Wolff for treatment. The case being a well marked one, I obtained permission to watch it for my own instruction. The patient's power to write was tested at intervals of three or four days, from January 14th to February 18th, 1885, on which latter date she considered herself as cured. (See series of facsimiles.) I append a few notes concerning this patient. Her age was forty-three, and the first symptoms of her complaint date from 1871. She then experienced a mere feeling of fatigue and discomfort in the arm on writing. Till 1875 no change was noticed except an increasing powerlessness; though she tried to write a little, this became so accentuated that she had to give up almost every attempt. She rested for some years, during which the feelings, which had in the meanwhile assumed the character of pain, persisted, and even extended upwards to the shoulder. Tremors in both arms made their appearance, occurring first on performing other actions than writing (combing the hair, &c.), and finally persisting for the whole day. No treatment seemed to give her any relief. When I saw her the act of writing was almost impossible; it took her five minutes of effort and pain to trace eight or ten very shaky letters. As the treatment proceeded the symptoms gradually subsided. On the 6th the persistent feeling of pain in the arm had disappeared. She could then write for a few minutes. The motor symptoms gave way also, as is well shown by the series of facsimiles. The specimen taken on the 9th February coincided

with a menstrual period, and shows an accidental increase of the tremor.

A general idea of Mr. Wolff's plan of procedure will be gained by a perusal of the article already referred to, or of the paragraph I have devoted to it in the "Year-book of Treatment," recently published by Messrs. Cassell and Co. I need only repeat here what I have previously said—viz., that there is no secret connected with it. Personal dexterity and the experience of many years' assiduous observation and practice are the elements of Mr. Wolff's success.

Welbeck-street, W.

ON THE

NON-MALIGNANT TUMOURS OF THE SPERMATIC CORD, AND THEIR DIAGNOSIS FROM HERNIA.[1]

BY EBEN. WATSON, M.A., M.D.,
SENIOR SURGEON TO THE GLASGOW ROYAL INFIRMARY.

I DO not intend, in this paper, to enter at all upon the literature of my subject, but merely remark that it is wonderfully scanty, and what there is of it is not quite of such a kind as to solve many of the doubts and difficulties which surround this class of cases. It may, however, be well to recall the fact that the diagnosis of tumours of the cord, both as to their exact nature and as to their differentiation from hernia, has been found by the best and most experienced surgeons so difficult as sometimes to have been declared by them impossible without cutting down upon the tumour, which is often by no means desirable from the patient's point of view. I have therefore thought that if practical surgeons would more frequently put on record a minute and accurate account of such cases of this kind as were presented to them, the sum total of their observations would lead to a better understanding of what is at present rather a surgical puzzle. I know, and feel very much, in commencing this paper, that the very doubtfulness of many of these cases, and the imperfect or unreliable histories which operating surgeons too often obtain of their early progress, combine to make it very difficult to write about them as one would wish to do; yet that difficulty is the very reason why such an attempt ought to be made, and the very foundation of the appeal which I should like to make to all clinical surgeons to institute more careful observations in these cases, and to record the results more frequently than hitherto. The present paper is intended as a contribution in this direction towards the elucidation of what I venture to call one of the most difficult chapters in surgery.

For practical purposes the simple or non-malignant tumours of the spermatic cord may be divided into the fluid and the solid, the former being, on the whole, the more frequent of the two. They consist of œdema of the cord and the so-called hydroceles of that organ. It must be remembered that the areolar tissue, which supports the elements of the cord, is continuous with a very considerable amount of the same tissue in the pelvis—viz., that which connects the transversalis fascia with the peritoneum; so that when œdema occurs in the cord, it may pass up or be pressed up within the inguinal canal and into the same structure within the pelvis. Thus it may be made altogether to disappear from the swelling in the cord, and lead to the idea that the case is one of hernia, unless the special features of the pathological condition are attended to. These will best be shown in an example.

On May 3rd, 1884, a patient, aged seventeen, was admitted to one of my wards in the Royal Infirmary. He stated that he had had what he believed to be a rupture for some six years. It had at first appeared suddenly as a swelling in the right groin, and when he consulted his doctor he confirmed his opinion of its nature. The swelling was soft, and extended a little way into the scrotum. It was readily reducible on pressure, but on lying down it did not disappear till pressed on by the hand. By the advice of his doctor he wore for eighteen months a truss, which kept it up very well; but the truss got broken, and he did not buy another, so that the swelling remained down in the groin and scrotum. He does not seem to have attempted to reduce it after he gave up wearing the truss. One morning, however, about a fortnight before admission into the infirmary, he awoke with a feeling of constriction at the upper part of the abdomen, and pain in the right groin, especially on coughing. He then noticed that the swelling was much larger than usual, harder, and that it extended to the lowest part of the scrotum. He then tried to reduce the supposed hernia, but failed; and he therefore applied for advice at the dispensary of Anderson's College, where he was advised to go to the infirmary. On admission there was found the swelling as above described, involving the right testicle, and extending up into the inguinal canal. It was tense and elastic, with a softer part in front, and rather to the inner side of the swelling. The skin over the tumour at the lowest part was red, and there was no distinct impulse given to it on coughing. There was no sickness, and the bowels were easily opened by castor oil. Fomentations were applied, and in a day or two fluctuation could be detected at the lower part of the tumour, a little above and in front of the testicle. An incision was at once made into this part, and a considerable quantity of pus evacuated. The director was then passed up into the inguinal canal, and another opening made in the upper part of the abscess. A small drainage-tube was pulled through the openings, and the usual antiseptic dressings were applied. Some purulent discharge continued for a few days, but it soon diminished so much as to allow the tube to be withdrawn, and the boy left the hospital quite cured in about three weeks from his admission.

I have no doubt that this was a case of slow œdema of the areolar tissue of the cord, which ultimately became acute and ended in suppuration. For the early part of the history we have only the patient's statement to rely upon, but it may, I think, be received as accurate so far as it goes. The swelling appeared first in the groin, occurring without known cause, and slowly progressing downwards into the scrotum. It could be reduced, or at all events diminished, by pressure with the hand, but always reappeared when the pressure was taken off. We are left in doubt as to the completeness or incompleteness of this reduction, and also as to the effect on the tumour of forcing a cough at this time. Afterwards, when I saw him, there was no such impulse on coughing as there would be in a case of hernia, and there was no diminution of the swelling in any posture or by gentle pressure. I regret that it is not stated in my notes what interval of time elapsed between his giving up the use of the truss and the occurrence of the acute inflammation, but one can easily understand that the pressure of a truss in this case might cause irritation and bring on such an attack. It therefore seems to me a good illustration of the evil which may follow from the too often routine practice of ordering a truss for every swelling, even if only partially reducible, which may occur in the position of an inguinal hernia.

Hydrocele of the cord may originate in the same way—viz., by œdema, not resulting in suppuration, but in the expansion of one or more of the areolar spaces containing fluid. It perhaps, however, more frequently originates in some small extravasation of blood, which after partial coagulation changes into a serous cyst. In either case, the diagnosis is comparatively easy if the tumour can be isolated and the cord felt above and below it; but this is not always possible, as the hydrocele may be partly included in the inguinal canal. Nay, it is possible that in some rare cases the fluid may pass up into the abdomen of the patient and entirely disappear in the recumbent position. This occurrence has been explained by some writers as due to the non-obliteration of the "processus funicularis" of the peritoneum; but I think it may also be accounted for by the occurrence of two areolar cavities containing fluid as the result of œdema, one cavity being in the pelvis and the other in the cord. But this is mere speculation on my part, for I have not seen any such case, even in the infant, though I have treated a goodly number of them for hydrocele. In no case have I been able to press back the fluid above the internal inguinal opening.

In the cases of hydrocele of the cord which I have examined, there was little or no diminution of the tumour on the patient's lying down, and the impulse on coughing has appeared to me slight compared with that felt in a case of hernia. For example, about a year and a half ago an American gentleman consulted me for a tumour of the cord which had existed for several months. He had a hernia on the right side, for which he wore a truss, and on the left side a long oval- or pear-shaped tumour, the narrow part of which was included in the inguinal canal and the larger part extended downwards towards the scrotum. The cord could be felt below but not above it. The impulse on coughing was slight, and it did not disappear, though it diminished and softened in the recumbent position. It was translucent and free from pain. His general health was quite good, but the swelling had been slowly increasing for several weeks. The nature of the tumour had been rightly diagnosed some time previously by a surgeon in London, who had drawn off the fluid, and therefore it was the more readily punctured by me with an aspirating needle, when some ounces of clear serous fluid were withdrawn. The cord was then felt clearly, and there was no evidence of hernial protrusion.

---

[1] Read before the Medico-Chirurgical Society of Glasgow, April 3rd, 1885.

But sometimes the matter is not quite so easily cleared up—as, for instance, in the case of a man who was brought to the Royal Infirmary from the country with all the symptoms of strangulated inguinal hernia. He had worn a truss for years when these symptoms arose, and on admission I found a much larger tumour than in the previous case, involving great part of the cord, but still not extending into the scrotum. There was at that time no impulse on coughing, and the tumour was pear-shaped, the neck of it being in the inguinal canal. It was quite smooth and too tense to be distinctly fluctuant, yet it gave to the fingers the feeling of fluid more than of solid contents, but it was not translucent. Nevertheless, I believed it was not a hernia, but a hydrocele of the cord, and I said so to the students and others around me at the time. I also gave it, however, as my opinion that in all the circumstances of the case the best practice was to cut down on it and incise it, which I thereupon did. There was no hernia, but a considerable quantity of reddish serum. The wound healed readily, and the man left the hospital radically cured of the hydrocele and relieved from the fear of hernia, of which he had no trace. Of course the constipation and sickness had easily yielded to proper treatment of a very simple kind.

I have little doubt that this last case was an example of the origin of hydrocele of the cord in a blood-cyst from the patient being a working man and in the prime of life, and also from the serum being still coloured with hæmatin when evacuated. The other case, being that of a gentleman in easy circumstances and of pretty advanced age, was, I think, an example of the origin of this affection in œdema of the cord, or possibly in a partially unobliterated funis. Of course, as I told him, if the fluid was found to reaccumulate rapidly and to be a trouble to him, he might require to have it injected with tincture of iodine and radically cured; but this could not be thought of while he was merely travelling, as he then was, in this country.

(To be concluded.)

A CONSTANT ANTISEPTIC VAPOUR DRESSING.

BY J. C. VOIGT, M.B., C.M. EDIN.
LATE RESIDENT MEDICAL OFFICER, BURY DISPENSARY HOSPITAL.

SINCE Schultz first proposed the employment of the oil of eucalyptus in surgery numerous cases showing its value as an antiseptic have been published (e.g., by Siegen, in *Deutsche Medicinische Wochenschrift*, 1880, No. 30, and 1881, No. 14; and by Busch, in *Berliner Klinische Wochenschrift*, 1880, No. 39). For an antiseptic spray, the oil can be utilised by either filling the spray bottle with the pure undiluted oil or by employing a solution in rectified spirit (1 in 8). The first method, however, produces a spray which is so powerful as to make it almost intolerable for some nurses. Inhalation of the strongly irritating eucalyptus steam, when it is at all prolonged, is not very pleasant. It often occurs that one desires the constant action of a volatile antiseptic on a wound which is already, to a greater or less extent, septic. Syringing in such a case would do harm by breaking up union which has already taken place in part, and even were it possible to syringe out a wound with corrosive sublimate or some other antiseptic solution, without at the same time causing any disturbance to the healing process, the solution would not perhaps penetrate to all corners and recesses where an antiseptic vapour, constantly applied and renewed, would find its way. In cases of this nature, which I may best illustrate by the subjoined notes of one or two recently under treatment in the Bury Dispensary Hospital, the great value of antiseptic agents which volatilise at the temperature of the body is seen. A dressing which throws a constant antiseptic steam into the wound can be prepared. Plain ordinary gauze, unimpregnated with any other antiseptic material, can be kept (till required for use) soaking in pure eucalyptus oil. Before being put on the wound which is to be dressed, strips of this eucalyptus gauze are squeezed as dry as possible and then steeped in eucalyptus and olive oil (1 in 5). Thus prepared, the strips of gauze are put on the wound, and immediately over them are applied some folds of ordinary absorbent cotton-wool, which have been freshly wrung out of the pure eucalyptus oil. The thickness of this dressing can be made to vary with the amount of discharge expected from the wound, and, if thought necessary, some dry antiseptic absorbent dressing material can be put outside this moist eucalyptus dressing. The wool, impregnated with eucalyptus, however, very soon dries at the temperature of the body, and its power as an absorbing dressing is higher than one would at first suppose. The deep dressing may be as above described, or may consist of gauze strips steeped in a solution of eucalyptus oil in rectified spirit (1 in 8). In twenty cases treated in Professor Busch's wards (Bonn), the pure undiluted oil was applied directly on wounded surfaces without causing the least pain, even in children.

CASE 1.—P. H——, aged four, was admitted into hospital on Nov. 12th, with injury to the left hand. There was a large open wound parallel to the fifth metacarpal bone, a wound also on the dorsum of the hand between the thumb and index finger, and a compound fracture of two metacarpal bones. After the wounds had been stitched and syringed out with corrosive sublimate, a sublimated dressing was applied. In the evening of Nov. 15th this dressing was saturated with discharge, and the wound, when examined, was found not to be aseptic. Frequently repeated changes of dressing and syringing with corrosive sublimate failed to make it sweet. On Jan. 3rd there was still a good deal of discharge, which smelt very offensively. The eucalyptus dressing, as above described, was applied and left *in situ* for a fortnight. On Jan. 17th the eucalyptus dressing was removed. The odour of the eucalyptus was still distinctly perceptible in the absorbent cotton, which was of a yellow colour and quite dry. The wound was found to be nearly healed up, and there was no bad smell.

CASE 2.—E. O——, male, aged forty-two, was admitted on Dec. 15th, having received an injury to his foot by a heavy weight falling on the dorsum. The first metatarsal bone was fractured (compound), and the metatarso-phalangeal joint was open. The open joint and the entire wound were well syringed out with corrosive sublimate solution. The edges of the wound were brought together by antiseptic stitches, and a dressing of absorbent cotton, steeped in pure eucalyptus oil, was applied. All this was done under a eucalyptus spray obtained from pure eucalyptus oil in the spray bottle. The dressing was left on for twenty-two days. During all this period the odour of the eucalyptus was distinctly perceptible at the patient's bedside. There was no elevation of temperature above the normal at any time. On the twenty-third day the dressing was removed. A small amount of blood and discharge was contained in the deeper layers of the wool, but there was no wounded surface, not even a single granulation left. A firm, healthy, pinkish-coloured cicatrix, outside which the ends of the catgut sutures were lying loose, existed where the wound had been. The joint was somewhat stiff. The patient was soon afterwards discharged cured.

CASES 3 and 4 were severe scalds. The one case was that of an adult male who had both feet extensively injured by a kettle of boiling water having been upset on them. The other was that of a girl eight years old. This patient had met with a similar accident, which had caused serious scalds of both arms and of the face. Both cases were septic when admitted, and in both a single application of the eucalyptus dressing at once corrected the disgusting fetor. The dressings were left on for five days. At the end of that period healthy granulating surfaces were exposed when the dressing was removed, and the wool still smelt strongly of eucalyptus. The cases then progressed fast towards recovery, and the remarkable power possessed by a eucalyptus dressing of promoting the rapid formation of healthy granulations, and at the same time causing processes of firm cicatrical tissue to spread inwards quickly from the margin of the wounded surface, was beautifully demonstrated in the course of both of them.

CASE 5.—On Jan. 9th I performed excision of the hip for disease of that joint in a boy aged four. Sero-sublimate gauze dressing was applied, but had to be removed on Jan. 16th, for the discharge had soaked through the dressing, and two long sinuses, which communicated with the wound, were found discharging a septic pus, although at the time of the operation they had been scraped and syringed out with corrosive sublimate solution (1 in 1000) and then plugged with sero-sublimate gauze. The patient's temperature also had risen on the night of the 15th. On Jan. 16th, with eucalyptus spray playing on the wound, after the strips of gauze had been removed and the sinuses well syringed out with corrosive sublimate solution, the eucalyptus dressing as above described was applied. Next day the patient's temperature was normal, and for more than a week afterwards the odour of the eucalpytus was strongly marked all round the bed, the patient's temperature remaining normal.

Bury.

WHEAT-MEAL BREAD; ITS ALIMENTARY VALUE COMPARED WITH THAT OF WHITE FLOUR BREAD.

By DR. CAMPBELL MORFIT, F.I.C., F.C.S.

THERE is such a diversity of chemical opinion as respects the nourishing potentiality of wheat-meal breads, that a satisfactory solution of the question by chemical analysis alone would seem to be difficult, for the present at least. But if we leave the chemists disputing among themselves, and pass from the domain of speculative philosophy on to the safer ground of practical science, mystification is seen to clear away at once, and there is revealed to us by the logic of facts the true state of the case, which I will now endeavour to explain.

Whole wheat-meal bread was the kind upon which the Roman army fed in the time of Julius Cæsar; and in the earlier part of this century Dr. Sylvester Graham, of New England, recommended its use in the United States, where it is now known as Graham bread, and is highly appreciated by bread consumers generally. But until I made the process for the granular form of wheat meal and gave it to the London Bread Reform League, whole meal was coarsely ground and contained its bran as dense flattened scales with sharp points and rough edges, which rendered it irritable to digestive organs the least sensitive. My improvement, which removed these defects entirely, secured for the granular meal a widespread popular favour that has not become universal only because the millers and bakers, failing to understand the philosophy of its manufacture, allow both it and its bread to degenerate into irregularities. Granular wheat meal, unlike the ordinary whole meal, not only makes more toothsome breads, but ensures the maximum degree of assimilation, because it is without that mechanically stimulating effect which hurries the whole meal through the alimentary duct before it has had time to yield all its nourishing matter to absorption. Whatever small portion may be excreted has yet acted an essential part in the process of digestion at least, though we may not be able to define it at present.

There are chemists who encourage a wasteful mode of milling by repudiating the long-accepted doctrine as respects the physiological relations of the nitrogenous compounds of wheat. Their scientific contention not only splits the nitrogenous matter of food substances into divers phases with differential properties, but apportions to each a differential estimate of its nourishing capabilities. One of their tenets in this connexion is that, however much nitrogenous matter may be present, only that portion of it distinguished by them as albuminoid, and which exists as protein (the basis of albumen, casein, fibrin, and the like), is potential for the nourishment of mankind. Indeed, some go so far as to suggest that even a part of the albuminoid nitrogen is of doubtful efficiency in that respect; and dividing the nitrogenous matter into two phases, one coagulable by acids and the other not, they throw out the latter as unavailable food matter. Its proportion may and does vary so widely in the same kind of food as to amount to as little as 5 per cent. in some samples of wheat, and rises to 34 per cent. in others; but these great discrepancies do not affect their judgment in the least. By this social arrangement in chemistry they ostracise nüclein, plastin, and their congeners, as dietetic pariahs; and in the case of wheat, they would relegate to the cattle food bin all of the branny portion which, though representing about a fifth of the total nitrogen of the grain, contains most of it in other phases than the albuminoid—notwithstanding, too, that it carries with it most of the fat and phosphates, and the whole of the cerealine, the digestive ferment natural to the grain.

But while convinced by recent experiences that every part of the wheat grain is food for mankind, I know also that a portion of the branny integument, amounting to 6 per cent. of the whole grain, detracts from the toothsomeness of the baked loaf. Practically, therefore, this tough husky modicum is objectionable in a bread sense, and decortication does not remove it, nor can it be separated from the meal when the wheat grain has been ground in a steel mill. My old process conceded to the Bread Reform League, consequently, must be discarded, because it involves both decortication and the use of steel mills. I now not only make the elimination of the tough bran an incident of the grinding operation, and save any outlay for the purpose, but simultaneously render the tender portion yet more loose and soft in texture, and consequently am able to produce at the minimum of waste and cost, firstly, a standard granular meal of refined character, representing from 93 to 94 per cent. of the cleaned grain, and always uniform in quality and features; and, secondly, a pearl-white meal representing all the farina of the grain with some cerealine, or about 83 per cent. of the whole, and affording a superior material for a white loaf to excel the "household" bread of the bakers. The perfection of these meals facilitated my subsequent improvements in bread-making, and the two combined not only accomplish a saving of 10 to 15 per cent. in the milling operations, but will supply standard meals and breads at less cost than usual.

As yet the public have not had the opportunity for testing the great advantages of genuine wheat-meal breads, because bakers in this country are unable or unwilling to make them properly, and millers do not supply suitable meals. Wheat-meal bread as it should be is attractive in appearance, and very unlike the poor stuff sold as such in the London shops. Whether made by fermentation or without, its basis is granular meal free from any of the usual admixtures or substitutes of white dough or dusted bran and white flour. Its crust is tender and smoothly granular, instead of being rough and hard, and, in the case of fermentation breads, deliciously crisp. The crumb, vesiculated, light, and elastic, is never sodden or too close, becomes stale slowly, has a rich mealy taste, and when chewed excites the salivary secretion. The bran particles are invisible to the eye, even through a magnifying-glass, and, save that they impart an agreeable taste, scarcely betray their presence to the tongue. The outward features and inherent qualities of the breads of my system are characteristic and uniformly the same. Not only are they appetising, but, weight for weight, much more nourishing than white flour breads.

In realising this standard excellence for meals and breads I employ only the usual means, but manage them in unusual ways so as to produce new and important effects. Success is obtained in my system of procedure, not by adopting the dogmas of those chemists whose culte is the aristocratic albuminoids, but by practising a rational philosophy of conflict with them. I act upon my belief that each food substance carries, naturally, an adjuvant of digestive ferments peculiar to itself, as wheat bears cerealine, and which, when loosened from its bonds by compatible means, receives the impulse to co-operate in preparing its associate constituents for digestibility in the human stomach. The observance of this principle has enabled me to convert even milk into a cheese of characteristic toothsomeness and digestibility, chiefly because the latter reclaims and embodies the wealth of essentials now run to waste in the whey. Even my pearl meal, therefore, is made to retain as much as possible of the cerealine matter of the wheat; and when either it or the granular meal is mixed into dough, water is made to set free the digestive ferment for action. This done, the dough, without being touched with the hands, is partitioned in a manner to protect it against injurious influences or changes during fermentation in any weather, and to ensure its perfect cooking in the oven without risk of spoiling a loaf by scorching or otherwise. The water is confined within the loaf until it has co-operated with the cerealine in developing the digestibility of the dough, and in promoting the baking or rather cooking of it into perfect bread; so that the portion necessary for its constitution remains in the loaf as a fixture, the excess passing off only when it has done its part in the cooking.

The crumb and crust of the breads made by my system contradict impressively the arguments against whole wheat meal. But chemical analysis obtains so little interpreting assistance from physiological research in the premises, that it occurred to me to seek a fuller understanding of the subject in a way quite different from any hitherto conceived. That is, having satisfied myself, by oft-repeated practical experiments, that standard breads in every respect can be made with wheat meals, I contrived a method which, though not strictly classical, is one of practical science, for determining what modifications their material undergoes during conversion into bread to render them characteristically superior to any others of the kind. Four different typical wheats (two white and two red) having been selected and first made into three meals—viz., one crude, representing the entire grain; another, the standard granular of my system; and a third, the pearl meal or *farina conels*, also of my system, both of which have been already described,—these meals were then converted severally, and according to my system, into non-ferment and fermentation breads. Scrupulous exactitude was observed as to all the weighings, dryings, and other manipulations, in order to make the results as trustworthy as possible. The first step was to ascertain the exact proportion of total branny matter in the several meals; and for this purpose a given weight of each was carefully but thoroughly brushed upon a very fine wire cloth until all its farinaceous portion had passed through. That which remained on the sieve, being direct from the meal, was designated *proximate bran*, and it varied in proportion, according to the kind of wheat, from 16·80 to 19·30 per cent. of the crude meal, and 10·58 to 13·24 per cent. of the standard meal, or a mean of 18·23 per cent. for the former and 12·19 per cent for the latter. Therefore, wheats generally may be said to consist of 81·72 farina and 18·28 branny matter per cent. The proximate brans of the different samples of crude and standard meals were next enclosed, separately, in very fine, white cotton cloths, and kneaded under relays of cool water until the latter ceased to become the least cloudy, and by this treatment they were reduced in weight rather more than one-half. The residue left I distinguish by the name of *absolute bran*, because it has parted with all its matter separable by the means employed. It will thus be seen that cool water alone has taken out of the proximate bran and into solution or intimate suspension upwards of 50 per cent. of its original substance. And what is no less remarkable, the ratio of absolute bran to the meal is a uniform fixed quantity for all the wheats indifferently, being 9·65 per cent. from the crude and 5·80 per cent. from the standard meal, notwithstanding that the proximate brans, whence they were derived, are variable in their quantitative relations to the meals. Therefore the total of actual bran in any wheat does not exceed 10 per cent.

Not yet satisfied that this absolute bran was exhausted, I next proceeded to ascertain if the proximate bran would yield more of its substance to artificial digestion than it does to water, and therefore it was subjected, under proper conditions, to the action of diastase, pancreatin, and pepsin consecutively. The result proved that the 9·65 per cent. of absolute bran from the crude meals had become reduced to 7·87, or 18·44 per cent., and in like manner the 5·80 per cent. of absolute bran of the standard meals lost 21·38 per cent., having been lowered to 4·56 except for one of the red wheats, which gave rather less difference for both meals, and seemed to be erratic. As this residue could not be resolved further by any controllable means, it takes, logically, the title of *ultimate bran*; and it would represent the final state and proportion of the bran if the process of artificial digestion left it free from variable quantities of assimilable matter. But digestion outside of the human stomach does not correspond with that inside, however skilfully it may be imitated, for there is some force at work in the one which cannot be commanded in the other; and probably, therefore, yet more of the bran is assimilable under more natural conditions. At the worst, the standard granular meal of my system has only 4·56 per cent of undigestible matter. Very interesting, too, in this connexion is the fact that this absolute bran not only loses density in becoming ultimate bran, but also drops as respects its mineral matter from 5·36 to 0·33 per cent. for the crude meal, and from 4·33 to 0·43 per cent. of the standard meal; or, in other words, the 2·42 and 2·36 of phosphoric acid which they represent fall nearly to zero, being drawn out by the process of digestion. Moreover, the total nitrogen, 2·17 per cent. (containing albuminoid nitrogen, 1·80), of the crude meal brans becomes 0·82 (containing albuminoid nitrogen, 0·78); and under corresponding circumstances the total nitrogen, 1·92 per cent. (containing albuminoid nitrogen, 1·86), of the standard meal brans falls to 0·80 per cent. (containing 0·80 albuminoid). Thus, although artificial digestion draws out the whole of the phosphates or mineral matter, and 60 to 70 per cent. of the nitrogenous matter, that portion of the latter which it leaves is—wonderful to be told—all or nearly all albuminoid.

Results could not be more impressive than these as to the superior nourishing value of whole wheat meal, for they prove that the separation and rejection of the bran must inevitably impoverish the residual farina or flour. This fact obtains additional confirmation in my own every-day life, for whole-meal bread, which forms four-fifths of my restricted diet, nourishes me satisfactorily; whereas any attempt to vary it in the least, with fine white flour bread, brings back bodily discomfort and debility. In the course of my laboratory work upon this subject, I also learned that, unusually fine as are the fermentation breads of my system, non-ferment breads can be made to excel them in every respect. But it is necessary to follow throughout a strictly philosophical method, and then they will require less time and labour in their manufacture, be independent of a choice of wheats and always sweet and appetising. "Baking powders," however, must not be employed for generating the carbonic acid gas which is to vesiculate the dough, as they leave chemical residues in the baked loaf which render it unwholesome. Nor must the carbonic acid gas be dissolved in the water for mixing the dough and forced in mechanically, for though it would aerate the loaf it will not produce perfect bread. To promote the hydrolysis whereby the cerealine with water replaces yeast, leaven and fermentation, and to facilitate the osmotic action upon which the metamorphosis of dough into bread largely depends, the carbonic acid gas must be in the nascent state and generated within the dough.

Alexandra-road, N.W.

CASE OF DOUBLE OVARIOTOMY.

By C. H. HAINES, M.A., M.D., M.CH.,
HONORARY SURGEON, AUCKLAND HOSPITAL, NEW ZEALAND.

THE following report of a case of double ovariotomy contains some points of special interest, which may render it worthy of insertion in the columns of THE LANCET.

E. R——, aged thirty-six, wife of a farm-labourer, a healthy-looking woman, married at the age of seventeen, came to New Zealand in 1874, having four children; since her arrival in the colony she has had three more, besides three miscarriages. She states that her mother died in childbed, at the age of thirty-two. She first noticed an enlargement of the abdomen in 1877. In September, 1883, she first experienced abdominal pain, which occurred after running a short distance. She applied then to Dr. Beale of Hamilton, who diagnosed an ovarian tumour of the left side. It caused very considerable enlargement of the abdomen, and extended about three inches above the umbilicus. The tumour was freely movable. It was increasing in size, and pain was constant. Two months later she came under my care in the Auckland Hospital (Nov. 1883). I aspirated the tumour, and through a large needle withdrew twenty-eight ounces of a jelly-like matter that became solid immediately; so thick and viscid was it that its withdrawal occupied an hour and a half. The size of the tumour was not very materially diminished after the operation. She then returned home. Her health was excellent, and the catamenia regular. Three months later Dr. Beale reported that the tumour was rapidly increasing and that her health was failing. The patient was suffering from dyspnoea and difficulty of micturition, and the tumour became so large that she was unable to move about. I then decided to operate and elected to do so at her own house in Hamilton, 100 miles from Auckland. On examination prior to operation, I found that the patient had assumed a cachectic appearance; the abdominal circumference at the umbilicus was forty-five inches; the womb measured three inches and a half, and was not movable. On Feb. 14th, 1884, assisted by Drs. Beale, Blunden, and Mr. R. F. Sandes, I operated. An incision of six inches exposed the tumour. Spencer Wells's cannula failed to withdraw the contents of the cyst. I then made an incision into the cyst sufficiently large to admit the hand, and brought away in successive handfuls some pints of a similar matter to what had previously been removed by aspiration. I was then able to pass the hand round the tumour. I found that it was irregularly lobulated and polycystic. A few adhesions to the omentum existed. The smaller cysts I broke down from within, and scooped out the contents with the fingers. The omental adhesions were tied in segments with fine whipcord, and a few bleeding points touched with solution of perchloride of iron. On examining the right ovary another tumour was discovered. It was about the size and shape of a full-sized fœtal head, perfectly smooth, with white opaque walls. Its contents consisted of thick cheesy matter, studded with fine hairs, and was evidently a dermoid cyst. The left pedicle was narrow and of medium length, the right short and thick. The right pedicle was tied in two segments with stout whipcord and returned; the left was secured with a Spencer Wells's clamp. The tumours being then removed, the abdomen was carefully cleansed with a 1 in 60 carbolic lotion, the wound secured with deep sutures of wire and superficial ones of carbolised gut, and a rubber drainage-tube inserted. A dressing of several layers of thymol gauze and an abdominal bandage completed the operation. The patient rallied well, and spoke cheerfully on recovering from the effects of the anæsthetic. Half a grain of morphia was administered hypodermically. Having to return immediately to Auckland, Drs. Beale and Blunden took charge of the patient. The highest temperature recorded was 101·8° on the afternoon of the day succeeding the operation. She had some vomiting, which was restrained by ice, and some attacks of pain, relieved by morphia. No drainage took place through the tube, which was removed on the fifth day. An enema given on the sixth day opened the bowels freely. The dressings were not removed until the tenth day, when the greater portion of the wound had healed, and the clamp separated. The sutures were removed on the twelfth day. From this time the patient made uninterrupted progress; the wound had entirely healed on March 10th, twenty-five days after operation, and the patient was able to resume her ordinary duties. The weight of the cysts and contents was thirty-six pounds.

Remarks.—The points of special interest in this case which induced me to report it are: the nature of the cyst contents, the complication with the large dermoid cyst, and the good results obtained under the different methods of treatment of the pedicle. No special antiseptic precautions were taken during the operation, but the apartment had been thoroughly cleansed with antiseptics. The abdomen was washed with a weak solution of carbolic acid, and the dressings were of an absorbent and antiseptic character, which admitted of their being left undisturbed until separation of the clamp had taken place. The district where the operation was performed is a thinly populated one, well elevated above the sea, and of a very healthy character. The house of the patient is an ordinary labourer's cottage, detached, and surrounded by eucalyptus trees; the time of year midsummer, with the temperature of the atmosphere in the apartment ranging from 65° to 70°.

Social Science Association.—The Council of this Association, have, after due notice given, unanimously passed a resolution to the effect that, in prospect of a general election in the month of November, it is undesirable to hold a congress during the present year. They have, therefore, been reluctantly compelled to decline the invitation received from the City of Bath to meet there in the forthcoming autumn, but they have expressed a hope that the invitation from that city may be renewed for the year 1886. It has, however, been referred to the Executive Committee for consideration, and to report whether a conference of a more limited nature should not be organised in London, on some special subject or subjects to which, in view of the opening of a new Parliament, it may be considered desirable to call attention.

HOSPITAL PRACTICE,

BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

CHARING-CROSS HOSPITAL.

TRAUMATIC ANEURYSM OF THE ULNAR ARTERY; OPERATION; RECOVERY.

(Under the care of Mr. Bellamy.)

Aneurysm of the arteries of the forearm, even of a traumatic character, is a rare disease, especially in the upper third; and the ulnar, from its position and depth, is less likely to be affected than the radial. The distance of the vessel from the surface, which is important in protecting it from wound, makes the operation which was required in this case more difficult of performance when the wound has been inflicted, and the presence of firm blood-clot, such as would be found eleven days after the injury, obscures the vessels when reached.

J. J. O'N——, a clerk in the Civil Service, was admitted on Jan. 12th with a wound inflicted with a desk knife, which entered about two inches the flexural fold of the elbow and rather to the inner side of the middle line, about a third of an inch long. Just before he came in the blood spurted out of the wound in great quantity. A firm compress was applied; and as there was no recurrence of bleeding and no appearance of a false aneurysm, he was on the 14th made an out-patient.

On Jan. 16th a little suppuration was observed in the wound, and on the following Monday night the pain was so severe from the tight bandage that sleep failed him. On the morning of the 20th he was seen by a private surgeon, who removed the tight bandage and syringed the wound out with carbolic lotion, after having pressed out a quantity of matter. On the following morning a sudden and severe spurt of blood occurred, estimated at about five ounces. Pressure on the wound stopped the bleeding. In the evening he was admitted, at 7 P.M., in consequence of a fresh and severe occurrence of hæmorrhage (about ten ounces).

Jan. 22nd.—The patient had his arm raised and very tight pressure applied over the wound by means of a pad. No fresh hæmorrhage has occurred since his admission to hospital. The patient looked somewhat blanched.

23rd.—As a fresh and unquestionably arterial hæmorrhage occurred in consequence of the bandage being loosened—the column was six inches high—Mr. Bellamy proceeded this day to operative measures. A tourniquet had been applied to the brachial artery to arrest bleeding. This was of course kept on during the operation. The wound was first enlarged, both up and down, with a probe-pointed bistoury, coagula of blood being found lying over the vessel and choking up the wound in every direction. On these being cleared away, the gaping open mouths of a wounded artery were seen. The vessel was as nearly as could be divided right through by the original injury, hanging together only by a thin shred. Mr. Bellamy ligatured the open ends of the vessel, divided the connecting links between the open ends, placed ligatures on one or two bleeding points, and cleared out all the clots, one of which had consistency in its walls, and could be called a diffuse traumatic aneurysm. The artery was unquestionably the ulnar, as the nerve was lying close to its inner side. Strict antiseptic precautions were observed; the wound was not closed, but a drainage-tube laid in and fastened with one stitch.

26th.—The patient is easy, and the wound looking healthy.

29th.—Granulations springing up of a healthy kind all over the wound. Drainage-tube no longer required. One catgut ligature visible. Patient still somewhat pallid.

The wound healed very rapidly, and the patient left, cured, on Feb. 10th, the circulation being thoroughly maintained in the hand and forearm, and there being no symptoms of injury to the ulnar nerve.

LEEDS UNION INFIRMARY.

THREE CASES, WITH POST-MORTEM EXAMINATION, ILLUSTRATING SOME POINTS IN CEREBRAL LOCALISATION OF FUNCTION.

(Under the care of Dr. Jas. Allan, Medical Superintendent.)

Case I. *Cerebral Softening: Paralysis: Death. Autopsy: Lesions of Basal Ganglia and of Third Left Frontal Convolution.*—Catherine F——, aged sixty-six, was admitted on Sept. 15th, 1882. She had been quite well and strong up to the 5th, when she had a fit and became paralysed on the right side.

On admission there was paralysis of the right upper and lower extremities, the facial muscles not affected; her articulation was thick and indistinct, and she complained of great pain in the paralysed limbs. The patient was emotional, noisy at night, but apparently unconscious of so being. The pain referred to continued throughout her illness.

On Nov. 17th she had an epileptiform fit, became unconscious and remained so, groaning continuously till death on the 23rd of November. After the fit the patient's face was strongly drawn to the right, and the right lower limb was firmly flexed on the abdomen. Reflex action exaggerated; the left lower limb sprawled about over the bed; reflex action subnormal. Both eyes were drawn to the right and upwards; the pupils dilated, but sensible to light. Saliva dribbled from the mouth; power of swallowing lost.

Autopsy a few hours after death.—Skull-cap very thick, half an inch at parts; membranes on the vertex of the brain opaque and thickened; a large amount of fluid in the membranes; the brain tissue generally abnormally firm, but a portion of the left hemisphere behind, and including the third left frontal convolution, was very soft on palpation, and here the membranes could not be removed without brain tissue adhering to them. On section of the right hemisphere the brain was found much too firm in consistence; the lateral ventricle was rather small; a very large artery entered the corpus striatum. Section of the left hemisphere showed that the left corpus striatum was softened to diffluence; there was also softening of a limited area of the contiguous anterior part of the left optic thalamus; softening also involved the left hemisphere from the corpus striatum outwards and upwards to the surface, including the posterior part of the third left frontal convolution. The softened tissue was greyish and darker than normal; there was no hæmorrhage, or evidence of old hæmorrhage. The whole brain weighed 38 oz.; the cerebellum and pons alone weighed 5½ oz. There was aortic incompetence; atheromatous degeneration of the valves and of the aortic arch; the left ventricle much hypertrophied; weight of heart 12 oz. The liver and kidneys were cirrhotic.

Case 2. *Convulsions: Loss of Sight: Death. Autopsy showed extensive Areas of Softening, including part of Optic Thalamus.*—James R——, aged sixty-four, a shoemaker, was brought in by the police on December 9th, 1882, having been found in an unconscious state. He gradually recovered consciousness, and in a few days was apparently quite well; his memory, however, was very defective; he had an anxious expression, as if in dread of some imminent danger, and complained of pain in the back of the head. Ophthalmoscopic examination revealed nothing abnormal. The patient was an inmate of this infirmary until his death, on June 12th, 1884. At intervals of six weeks or two months during his stay he was suddenly seized with very violent epileptiform fits, would continue two or three days after each attack dazed and ill, and then get about as usual. For a week before death he was, on account of the frequency and severity of the fits, entirely confined to bed. The muscular contractions were usually general, but always more marked in, and sometimes confined to, the left upper and lower limbs and the left side of the face. When not convulsed the patient was quite conscious, and had perfect use of his limbs. He became completely blind of both eyes four days prior to death. There was no pain referred to the eyes; sight not previously affected. It was found on inquiry that this patient had had two fits, one a year, the other six months, previous to date of admission. He was described as having been ill for three months after the first, and is said to have lost his speech for a time after the second seizure. There was nothing peculiar in the family history of this man; no previous illness; but he was much given to drink.

An autopsy of the head was made a few hours after death. The scalp was adherent; calvaria of normal thickness; membranes of the brain much thickened; a considerable amount of fluid in the subarachnoid space. There was a small osseous plate in the falx cerebri just over the crista galli. On removing the brain a large quantity of fluid escaped from the ventricles. Arteries at the base much degenerated, atheromatous, and calcareous. In the situation of the left supra-marginal lobule there was a large deficiency of brain tissue; the gap was triangular in outline, the two longer sides of the triangle, about one inch and a half each in length, were formed by the ascending parietal convolution and by the superior temporo-sphenoidal convolution; the base of the triangle, about an inch in length, was in the occipital lobe; in shape the gap was somewhat pyramidal; its apex reached the descending cornu of the left lateral ventricle on a level with and just behind the ventricular projection of the optic thalamus, and was only separated from the lateral ventricle by its ependyma, which was much thickened. Both lateral ventricles, much dilated, presented large vessels ramifying on their walls. The left corpus striatum and optic thalamus were normal in consistence. In the right lateral ventricle there was softening to diffluence of the floor behind and external to the optic thalamus; it extended close up to and included the posterior part of the optic thalamus to the depth of about half an inch. Both hippocampi were involved and the surrounding cerebral tissue, downwards to the inferior surface of the occipital lobe, and backwards—that part of the occipital lobe directly behind the lateral ventricle. The corpus striatum of the right side was normal, also the anterior part of the optic thalamus. The brain weighed 43¼ oz., the cerebellum and pons alone $4\frac{15}{16}$ oz.

Case 3. *Heart Disease: Hemiplegia: Death. Autopsy showed Softening of one Corpus Striatum and part of Optic Thalamus.*—William H——, aged thirty-seven, a slater, was admitted on March 24th, 1884, with paralysis of the left side. Paralysis came on after a fit on the day previous to admission. Cramps and numbness of the left lower limb preceded the fit a few hours. Just before his illness he had got cold and wet from working on a roof covered with hoar-frost. He had not had any illness; said he never had venereal disease; was a moderate drinker. On examination he was found to have complete motor paralysis of the left upper extremity, and nearly complete motor paralysis of the lower; muscles of the face not affected. He experienced intense pain referred to the right ear and radiating over the right side of the head; nothing abnormal detected in the right ear. The pupils were unequal, the right contracted and the left dilated. There was evidence of aortic disease and cardiac hypertrophy. The patient was ordered iodide of potassium in increasing doses, and blisters were occasionally applied behind the right ear.

April 5th.—Earache and pain not so excessive. Temperature 98°; pulse 66.

27th.—Progressive emaciation; headache. Retinal hæmorrhages were found on ophthalmoscopic examination; sight not affected.

July 8th.—Both pupils dilated, the left more so than the right; frontal headache. Temperature 98·2°; pulse 84.

15th.—He feels very unwell; headache frontal and above the ears. Temperature 103°; pulse 132.

17th.—Headache nearly gone; he is very anæmic. The patient is troubled with dreams, of the unreality of which he can with difficulty convince himself. Morning temperature 99·4°; pulse 84. Evening temperature 98·4°; pulse 96.

27th. Temperature normal; pulse 84, dicrotic.

August 4th. Temperature subnormal; frontal headache. Has Cheyne Stokes' respiration; the accelerated respirations are brought on by any change of position in bed or by coughing; pulse feeble and irregular, varying from 96 to 120.

7th. Respiration frequently of Cheyne Stokes' character. Temperature 97·5°; pulse 120; has a troublesome short cough.

8th.—Has dyspnœal paroxysms; distressed expression; not much headache. Evening temperature 98·8°; pulse 120 to 144 per minute.

9th. More intense dyspnœal attacks. Death took place, the immediate cause being œdema of the lungs.

The patient was confined to bed during the whole time of his illness. Soon after admission the use of the left lower limb was to a considerable extent recovered; he could get out of bed and walk fairly, dragging the paralysed limb.

aneurysm was occupied by a healthy granulating wound. On May 17th the patient was discharged with both wounds soundly healed. The author remarked that the aneurysm had formed so rapidly, had attained so large a size, its increase was so marked during the few days it was under observation, and the sac was so thin, that ligature was resorted to without any attempts to cure it by pressure. Mr. Walsham had collected all the cases of aneurysm in the groin published in the English weekly periodicals, &c., since 1870. They numbered sixty-seven cases. Of these, thirty-six were treated by pressure, or by pressure and subsequent ligature. In nine only was pressure successful; in two of the remainder pulsation ceased in the sac, but the patients died apparently from the effects of the pressure. In the rest, pressure failed entirely, and ligature had to be resorted to. But not only in these did pressure fail to cure the aneurysm, but it appears in fifteen to have placed the patients in a worse condition for subsequent ligature, and in some in considerable danger of their lives. In three or possibly four, death seemed attributable entirely, or in great part, to the pressure. In face of these results, Mr. Walsham was inclined to question whether, as generally taught, pressure ought as a rule to be attempted in aneurysms of the groin before resorting to ligature. Since the revival of the method of applying two ligatures and dividing the artery between them, this appears to be the first case in which it has been employed on the external iliac. The advantages claimed for the method are—1st, that it diminishes the risk of secondary hæmorrhage by removing longitudinal tension of the vessel, and by ensuring that no part of the artery above the upper and below the lower ligature is deprived of the nourishment it receives from its sheaths; and 2ndly, the artery being divided completely across, there can be no chance of its calibre being restored through the slipping of the knot, the too rapid absorption or giving way of the ligature, or the failure of division of the internal and middle coats. A restoration of the calibre of the artery from one or other of these causes has now in several instances led to a return of pulsation in the aneurysm, and in consequence, in some cases, to its rupture and fatal hæmorrhage. In the last place, Mr. Walsham advocated the leaving of the suppurating sac to nature, in place of incision, and turning out the clots as advised by many—a proceeding which has led to severe, or even fatal hæmorrhage. —Mr. Durham had seen a remarkable case of inguinal aneurysm twenty-five years ago under the care of Mr. Hilton. A silk ligature was placed upon the artery, probably the common iliac. Although suppuration of the sac ensued, the patient ultimately recovered; and four years later an aneurysm of the other side appeared, which was cured by compression of the common iliac artery by means of Pancoast's tourniquet. The patient lived five or six years, and then died of aneurysm of the aorta.—Mr. Charters Symonds said that the kind of ligature and the method were the points still under discussion. From Mr. Morris's and Mr. Hutchinson's statistics no comparison could be made between the relative values of silk, catgut, and kangaroo tendon as ligatures. He said that fresh statistics were required before we could arrive at a comparative value. At Guy's Hospital the use of catgut and antiseptics had rendered very infrequent the occurrence of secondary hæmorrhage.—Mr. R. J. Godlee asked whether the kangaroo tendon was rendered aseptic by any means, and also whether there were any signs of the ligature coming away. He had known such ligatures to come away some time after the operation; in a case of subcutaneous ligature of a nævus two months elapsed, and then a ligature was removed from the wound. He thought that double ligature with division was a sound operation.—Mr. T. Smith said that he was the first to do the operation of double ligature with division between at St. Bartholomew's Hospital. He had pursued this plan with every artery in the body except the subclavian. Last year he ligatured with kangaroo tendon the external iliac artery, with a successful result. Many of his colleagues were converted to this method, which was the one which Carden of Worcester had suggested to Mr. Smith many years ago. The double ligature did not allow of pockets of pus to accumulate, for the divided ends of the artery retracted to varying degrees according to the artery concerned. There was less risk of secondary hæmorrhage from an artery in a stump because the artery was relieved from all tension, whereas much elastic tension existed in a vessel ligatured in its continuity. The whole wound was laid open from the bottom if the artery were divided between the two ligatures, and nothing like a separate sinus existed between the artery and vein such as was the case when a single ligature was used.—Mr. Howard Marsh was one of those who had formed a favourable estimate of the method of double ligature with division of the vessel between. In this operation there was a greater certainty that the vein would not be wounded. In at least two instances he had seen the femoral vein wounded, and in one case the needle was passed through the vein, and pyæmia resulted. The division of the artery allowed of full contraction and retraction of the ends, as happened in *spontaneous arrest of hæmorrhage*. It was true that Mr. Syme had ligatured in their continuity thirty-one arteries without a fatal result, but such success it was not for everyone to expect. He thought it was far better to ligature the external iliac without attempting to cure the aneurysm by compression. Pain, delay, and uncertainty were the objections encountered in treating the aneurysm by compression.—Mr. Walsham replied that the kangaroo tendon was steeped in a strong solution of carbolic acid. He did not agree with Mr. Symonds, for he considered that the statistics which he had furnished, dating as they did only since 1870, supplied a comparison, for many of the cases had been treated antiseptically, and catgut and kangaroo tendon had been used.

Dr. Dickinson and Mr. Rouse read a paper on a case of Renal Lithotomy. The subject of this case was a young man who had been in St. George's Hospital under the care of Dr. Dickinson, as far back as 1877, with hæmaturia, due, as was considered, to stone in the kidney. He was last admitted in April, 1884. His age was then nineteen. His parents had been on the previous occasion advised to bring him up to a sedentary occupation, instead of which they made him a blacksmith. He suffered from repeated hæmaturia, brought on either by exertion on movement or by drinking beer, and had occasional pain in the right renal region. The urine was bloody, there was no albumen except what was due to the blood, and the diagnosis of stone in the right kidney appeared to admit of no doubt, while excepting the stone there appeared to be no renal disease. The patient was somewhat spare in frame, and appeared to be so favourable a subject for operation that Dr. Dickinson requested Mr. Rouse to undertake it. This was accordingly done on May 8th, 1884. An incision was made in the right loin as in Amussat's operation, the kidney exposed, and a stone felt inside it with the finger and with a needle. The kidney was then incised, a stone weighing sixty-five grains removed, and a smaller one felt, which eluded the attempts made to extract it. This, however, which was found to weigh only two grains, came away spontaneously on the fourth day after the operation. The larger stone was about as large as a filbert, the smaller the size of a pea. They were not cut, but presented the appearance externally of oxalate of lime. The urine discharged abundantly through the wound. The progress of recovery was interrupted by an attack of septicæmia, which was almost indistinguishable from pyæmia. A severe rigor occurred on May 22nd, and was repeated on many subsequent days. The temperature went up to 107°, and presented a daily maximum which for twelve days, with one exception, ranged between this point and 103°, while eleven days elapsed before it assumed anything like a normal level. The febrile attack was accompanied at its commencement by pneumonia, as was shown by the characteristic expectoration, and later by rheumatoid swellings of several joints, notably of the left elbow, wrist, and knee, all of which were red, painful, and tender, while the knee contained an appreciable amount of fluid. Quinine and stimulants were freely given, under which the adverse symptoms disappeared. The wound in the meanwhile had been healing without interruption, and on July 16th was closed. The patient was last seen on October 27th, when he returned to the hospital to show himself. He was in perfect health, and was about to resume his work as a blacksmith. The stones were exhibited.—Mr. Durham made mention of the fact that Mr. Thomas Smith was the first to advocate this operation, though he believed that he (Mr. Durham) was the first, in recent times, to attempt the operation of removal of a renal calculus; owing to a mistaken diagnosis no calculus was removed. Mr. Morris was the first to perform the operation successfully.—Mr. Smith thanked Mr. Durham for referring to his inauguration of the idea of renal lithotomy, and said that it was not till two months ago that he had had the opportunity of performing the operation. Even when the kidney was exposed it was sometimes impossible to detect the actual existence of a stone. He had recently removed the kidney for calculus, and yet thorough external exploration (the kidney was not punctured) failed to detect the stone. A detached calculus, with much phosphatic débris, was first seen on incising the kidney after its removal. He was not sure which would prove the less dangerous operation, nephrectomy or nephrotomy.—Mr. WALSHAM alluded to a case of nephrectomy which he had performed on a woman, aged forty-three, about two weeks ago. There was no hæmaturia at any time, but much pus in the urine; in the right lumbar region a large swelling existed. The kidney was reached by a lateral incision between the anterior superior spine and the left rib. A large branched stone was found, but he had to remove the kidney; the nephrectomy was accomplished after considerable difficulty; some collapse followed, but the patient was in a fair way of recovery; the urine was clear and free from albumen.—Dr. F. L. BENHAM said that Armstrong had advocated calomel as a treatment for pyæmia, and questioned whether the improvement in Dr. Dickinson's case did not result from the external use of calomel.—Mr. CHARTERS SYMONDS put the question whether, in a man suffering from renal colic or intense pain due to kidney disease, it was justifiable to remove the kidney. He referred to cases that had been under his observation, and to one in which a urinary abscess, situate behind the peritoneum, was drained: death ensued from peritonitis, which was not related to the operation, but was due to the primary renal disease.—Mr. WARRINGTON HAWARD was of opinion that exploration, even with incision, was far less dangerous than nephrectomy when the surgeon was doubtful whether a stone was present or not. He related a case in which all the symptoms pointing to a renal calculus were present in a young man: digital exploration and puncture detected no stone, but he did not proceed to remove the kidney, for he was very doubtful of the wisdom of such a procedure. In a case in which he had removed a stone from the kidney there was much suppuration; incision allowed of drainage as well as removal of the stone, and the patient did well.—Mr. R. J. GODLEE thought that our surgical experience had taught us that nephrectomy was a most dangerous operation, and likely to cause death in exhausted states of the system. Some old cases of kidney disease might be dealt with much more freely than was perhaps generally thought. He referred to a case of renal calculus in a woman from whom he had removed a stone first and the kidney later on; the shock was comparatively slight in both operations, and by the time of the second operation the kidney had shrunk to a very small size. He differed from Mr. Rouse, and thought it was possible to keep the wound aseptic notwithstanding the presence of urine.—Dr. DICKINSON felt most strongly that the removal of a kidney was a most unwise procedure when incision would effect practically all that was necessary. He did not think that the calomel had much to do with the recovery of the patient from the pyæmic-like symptoms.

Mr. R. W. PARKER showed a little girl, aged five, in whom he had performed thyrotomy for papillomatous growth in the larynx seven months ago. Recovery followed, with preservation of voice. A paper on the case will be read in full in the early part of next session.

Mr. J. R. Lunn showed: Four cases of Osteitis Deformans and microscopical sections of Diseased Tissues. Mr. Rushton Parker: A case of Ununited Fracture of Olecranon, wired antiseptically, with close union of fragments. Dr. Stephen Mackenzie: (1) A case of Osteitis Deformans; (2) A case of Hereditary Multiple Tumours. Dr. Hadden: A case of Obstruction of Arteries and Veins which had lasted many years.

HARVEIAN SOCIETY OF LONDON.

A MEETING of the above Society was held on April 16th, Dr. T. Morton, President, in the chair.

Dr. R. W. BURNET read notes of a case of Ulcerative Endocarditis, which had been under his care for two months in the Great Northern Central Hospital. The earliest complaint had been of slight pains and swelling of the limbs. The symptoms having become acute, the patient was admitted into hospital. She was then weak, pale, and somewhat emaciated; skin dry and harsh; pulse 110; temperature 102·5°; respiration [illegible]; heart's impulse normal; a systolic thrill, and a systolic murmur audible at apex and in the axilla. Ulcerative (or infective) endocarditis was diagnosed. The patient gradually got worse. The temperature varied from 100° to 104·5° F.; and the pulse from 120 to 130; the murmur became very rough and the urine albuminous, and the patient gradually sank. Post-mortem: Lungs congested and œdematous; pericardium thickened and adherent; ventricles thickened and dilated; mitral valve thickened, but smooth; posterior surface of left auricle covered with adherent vegetations; aortic valves incompetent, thickened, and thrown into folds; aorta healthy; large infarct in spleen, and two other infarcts of older date. No noticeable changes in the other organs. Dr. Burnet gave abstracts of three other cases, one of which had been under observation for four months. In this case there were, in addition to extensive disease of the heart, pleurisy, pneumonia, and pericarditis. The heart was very large, hypertrophied, and dilated; the mitral valve and chordæ tendineæ much thickened; on the mitral and in the left auricle numerous vegetations; emboli in the spleen and left kidney. In one of the other cases there was gangrene of the foot. Dr. Burnet pointed out that the first case was typical of a class of cases in which endocarditis followed upon old rheumatic mischief, and that the rheumatic symptoms need not be severe, although the cardiac affections may ultimately prove fatal. Dr. Burnet alluded to the recent Gulstonian lectures by Dr. Osler, and quoted the views of the latter in reference to this form of endocarditis.—Dr. BROADBENT commented upon the pathology of the affection and upon the usual modes of death. Occasionally cases might recover; of this there existed clinical as well as anatomical evidence.—Dr. EWART called attention to the fact that fatal endocarditis often ran its course without any ulceration. Applied to such cases the term "ulcerative endocarditis" was a misnomer. It might be well to discontinue the use of the prefix.—Dr. J. WILLIAMS referred to a case of the disease occurring in the puerperal state. Independently of endocarditis, cardiac murmurs were very common in puerperal women.—Dr. ANGEL MONEY had recognised the presence of a bruit over the site of the left auricle and at the fourth cartilage in 60 per cent. of Dr. Williams's puerperal patients. This was probably due to the hypertrophy and dilatation of the heart, and to physiological changes in the composition of the blood.

Mr. J. ERNEST LANE read a paper on Hæmophilia. Having dwelt upon the hereditary nature of the affection, he referred to its marked prevalence in the male sex. In the female the disease probably remained in a latent form. Thus the daughters of a male patient, although exempt, might transmit the idiosyncrasy to their sons, whilst the direct male descendants remained healthy. Attention was also drawn to the fact that "bleeder" families were unusually prolific, the number of births being almost double the ordinary average. The comparative rarity of the disease was explained by the fact that in these families the number of sons far exceeded that of the daughters. Of thirty-seven children born in six of these families, twenty-seven were boys and ten girls. The symptoms were classified under the following headings: 1. Spontaneous bleedings. 2. Traumatic bleedings. 3. Effusions into joints. Referring to this last symptom, Mr. Lane considered that the swellings of the joints were usually due to synovial, and not to hæmorrhagic, effusion. The views of Virchow and of Wachsmuth as to the pathology of the disease were quoted. With regard to treatment, he recommended the habitual use of purgatives, such as sulphate of soda or compound jalap powder. The hæmorrhages should be treated by the use of styptics, preference being given to the perchloride of iron. He referred to a case in which transfusion had been performed by Dr. Samuel Lane when the patient was on the point of death from hæmorrhage induced by an operation for squint.—Dr. M. HANDFIELD JONES briefly narrated an example of the disease which had come under his notice in which the diathesis had been traced through three generations. There was apparently a close connexion between the number of members in a family and the fatality of the disease, the percentage of deaths from bleeding increasing as the number of children became larger. Moreover, among the younger children hæmophilia proved more rapidly fatal than in the earlier members. Dr. Handfield Jones differed from Mr. Lane in thinking that hæmophilic patients rallied quickly from large blood-losses. Mr. SEDGWICK looked upon hæmophilia as a congenital defect of the vascular system, and upon the associated affection of some of the joints as usually due to effusion of blood. The female transmitters did not exhibit any exceptional tendency to hæmorrhage even during childbirth. Families of bleeders both in this country and in America probably inherited the defect in many cases from a common source, through the occasional extension of the usual limits of atavism. In some forms of the diathesis, such as epistaxis, hæmoptysis, and umbilical hæmorrhage, the structural defects in the bloodvessels was more limited than it was in hæmophilia.

MEDICAL OFFICERS OF SCHOOLS' ASSOCIATION.

The annual meeting was held in the Medical Society's Rooms on Wednesday, April 18th, Dr. T. Fuller, President, in the chair.

Dr. **Alder Smith** reported that nearly six hundred copies of "The Code of Rules for the Prevention of Infectious Diseases in Schools" had been sold and distributed since the last meeting in January; and that the following gentlemen had joined the Association: Dr. Richards, of Winchester; Dr. Newsholme, of Clapham; and Mr. Brudenell Carter. The following members were elected on the Council in the place of four retiring: Dr. Briggs, of Harrow; Brigade-Surgeon Clarke, of Sandhurst; Dr. Fletcher, of Highgate; and Mr. O'Brien Jones, of Epsom College.

Dr. Withers Moore, of Brighton, and Dr. Littlejohn, of London, were elected members of the Association; and Dr. Thorne Thorne as the first honorary member.

Mr. **Brudenell Carter** then read a paper on Eyesight in Schools. The author commenced by setting forth the great importance of the question, not only to the scholars of the present generation, but also, possibly, to their descendents, and dwelt upon the necessity of caution in arriving at any conclusions upon the subject. He then proceeded to describe at length the peculiarities of the several conditions of refraction, emmetropia, hypermetropia, myopia, and astigmatism, the signs by which they were recognised, the sources of error in diagnosis, and the effects upon vision and comfort which they respectively produced. He discussed the view maintained by Donders, of the essentially diseased condition of the myopic eye; and showed that, although not universally correct, it was correct in the majority of instances, especially in all those in which the myopia was progressive in its character. He referred to a doctrine lately put forward by Mr. Berry, to the effect that increase of myopia might be regarded merely as a consequence of physiological growth, and showed this view to be incompatible with the clinical history of the affection, and also with the normal rate and amount of growth in the eye. After glancing at the original statistics by which Cohn, in 1867, called attention to the prevalence and progressive increase of myopia in German schools, he said that Cohn's investigations had now been repeated in various parts of the world by at least forty observers, and upon at least 50,000 children; and that, while different observers brought out different results as regarded the relative prevalence of various forms of defect, yet that all were agreed in maintaining the accuracy of the general principles which Cohn had laid down. In England but little evidence had been collected, although Mr. Priestly Smith had found 5 per cent. of myopia in Board School children, and 20 per cent. among pupil teachers taken mainly from the same class; while Mr. Adams Frost had found about 20 per cent. of myopia among London Board School children. Still, these figures, although confirming those obtained in other countries, were not sufficient to serve as a foundation for practical deductions; and the author proposed to rest his case chiefly upon the results published by a medical committee in Philadelphia, a committee presided over by Dr. Risley, and which appeared to have conducted its inquiries with exceptional diligence and care. After giving an account of the methods pursued by this committee, the author cited their figures to show that the increase of myopia, which seems to occur in all schools, occurred mainly at the expense of the hypermetropia and the astigmatism; and he drew the inference that these eyes were especially vulnerable, and that they required to be watched over during the progress of school life. He then proceeded to criticise in detail some observations recently published by Mr. Roberts, which purported to give the results of an examination of the eyes of the boys at Marlborough College, and endeavoured to show that these results afforded no support to the encouraging conclusions which Mr. Roberts had drawn from them, and that they only showed a great and lamentable prevalence of defective vision in the school. Finally, he dwelt upon the necessity of paying attention to the early signs of ocular discomfort in young children, whether at home or in preparatory schools, or in the junior classes of large schools, and expressed a hope that the members of the Association would make inquiries into the facts of the case, and would place themselves in a position to give utterance to opinions which would rest upon the solid basis of knowledge. The paper was illustrated by numerous figures and diagrams.

A discussion followed, and the meeting adjourned after a vote of thanks to Mr. Brudenell Carter for his paper.

MIDLAND MEDICAL SOCIETY.

At the meeting held on April 1st, Mr. T. H. Bartleet, President, in the chair,

Mr. H. **Bracey** showed a case of Myxœdema. The patient, a woman aged fifty-seven, presented all the usual symptoms of the disease. Her sister died last June of myxœdema in a London infirmary. The patellar reflexes in this case were increased, and the urine contained a trace of albumen.

Mr. J. W. **Taylor** showed an Instrument for Dilating the Cervix Uteri.

Mr. **Chavasse** exhibited a patient, aged nineteen, who had suffered from Necrosis of the Radius ever since he was an infant. Sequestrotomy had been performed nine times, as latterly the symptoms seemed suggestive of myeloid sarcoma; the entire radius was excised a year ago. The patient had now a useful limb, being able to feed and wash himself, and carry an ordinary bucket.

Dr. **Garman** showed Crystals of Leucin and Tyrosin from a case of acute yellow atrophy of the liver.

Dr. **Suckling** showed a boy who had suffered from Pachymeningitis Cervicalis Hypertrophica. The disease began three years ago with rigidity of the neck, shooting pains along the great occipital and other nerves, followed by paralysis of both upper extremities with rigidity, the hands being strongly flexed on the fore-arms. Paralysis with rigidity of both legs followed. The patient had been under Dr. Suckling's care for two years, and recovered entirely, with the exception of a little twitching of the left knee.

Dr. **Suckling** also showed a man suffering from Perforating Ulcer of the Foot, which was the first symptom of locomotor ataxy. There were two sinuses, one on the under surface of each great toe, opposite the phalangeal joint, which did not lead down to dead bone. The patient had suffered from these sinuses for two years. Dr. Suckling saw him about twelve months ago, when there were no signs of locomotor ataxy; but when examined last March loss of patellar reflexes, swaying movements, and the Argyll-Robertson pupil had supervened. There was no anæsthesia or sweating of the feet.

Dr. **Neale** showed an Instrument for Irrigating the Uterus, made of vulcanite, the chief object of its design being to combine in one piece the smallest injecting-tube with as roomy an ejecting one as possible, so as to allow of the immediate removal of débris from the uterus. The makers are Messrs. Woodall, York.

Mr. H. **Lupton** read a paper on a case of Intra-cranial Hydatid. The patient, a girl aged thirteen, had noticed a swelling on the head for about twelve months, which, after discharging purulent material, subsided, and refilled again repeatedly. Mr. Lupton at first thought he had to deal with a suppurating cyst, and proceeded to operate with the intention of dissecting out the cyst wall, but no cyst was to be found. The bone was rough, and an aperture was felt leading into the skull. The hole was just large enough to admit the tip of the little finger, and when the finger was withdrawn it was followed by an ounce or two of fluid, and about a dozen daughter hydatids. The cavity was washed out and drained; daughter cysts occasionally came away, but in about a month the cavity ceased discharging. The hole in the skull closed up, and the girl got perfectly well. The site of the perforation was close to the occipital protuberance.

Dr. **Headley Neale** read a paper on the Germ Theory of Phthisis, pointing out the difficulty of harmonising the theory of the micro-organismal origin of the disease with the well-established fact of its heredity, the arguments employed pointing to the conclusion that physico-chemical changes must precede the botanical aggression. The subject of the antiseptic treatment of phthisis was touched upon, the author drawing attention to the difficulty of applying antiseptic material topically to the air vesicles and their phthisical contents.

WEST HERTS MEDICAL ASSOCIATION.

THE seventy-fourth annual meeting of the above Association was held at Watford on the 8th ult. Twenty-four members were present. The President, Dr. P. Hood, in the chair.

Dr. C. E. SAUNDERS read a paper on Cholera, its Cause and Method of Propagation. The author referred to India as the home of cholera, and gave some chronological account of its early history in that country. He traced its advance in 1817 to parts of Europe, and in 1831 to England, where it remained fourteen months; the next visitation was in 1848–49, then in 1853-54, and the last 1865-66. Dr. Saunders discussed the various theories that have been promulgated as to the cause of cholera, and showed that many observations, although carefully made, contradicted one another, and from this drew the conclusion that cholera could not occur without its specific contagion, and that meteorological or other conditions had little to do with the dissemination. The one factor constant in all outbreaks was filth in some form or other, and the pollution of water certainly, and possibly other media through this means, with the excreta of cholera patients, which had been conclusively shown to contain the germs. He showed, from the conclusions arrived at by the two international sanitary conferences which had been held at Constantinople and Vienna respectively in 1856 and 1876, that cholera was not carried by the air for any but very short distances from the source of infection, and that no instance of an outbreak had ever been known to occur in less time than it would take a man to travel the distance, or, in other words, that human intercourse was the source of propagation. Dr. Saunders believed that Professor v. Pettenkofer's theory as to the conditions that were necessary for the naturalisation of cholera was worthy of great consideration. Pettenkofer believes that a soil permeable to air and water and containing much organic matter, with a fluctuating subsoil water, are essential conditions for cholera propagation. Although it was probable that the cholera poison was of the nature of a microbe which was swallowed in water, the author considered it was premature to accept the belief that Koch had discovered the bacillus on which cholera depended. Dr. Saunders insisted that cholera was a disease *sui generis*, and that it was mischievous and misleading to use that term for any but Asiatic cholera, and especially objected to diarrhœa being qualified by the prefix choleraic. In conclusion, he laid down rules for the hygienic management of a case of cholera, especially alluding to the precautions necessary to be taken in dealing with the excreta, and the best method of disinfection, enjoining the use of a perfectly pure water and food free from suspicion of contamination, and urged that the safest thing to do if a case of cholera occurred was to cause a revolution of all pre-existing domestic arrangements so far as concerned those persons who remained well, with a view of preventing further extension of the disease while an investigation was being made into the cause of the first outbreak. -In a discussion which followed, Mr. Cayley gave his experience of twenty-seven years of practice in India. He gave most valuable information as to the treatment of the disease, and considered that in the comma bacillus of Koch a valuable means of diagnosis was to be found. The President, Dr. Brett, and Mr Stradling joined in the discussion.

Mr. FISHER showed some photographs of an interesting case of Ichthyosis, which had greatly improved under treatment.

WATER-SUPPLY OF EPPING.—Last summer and autumn there were fully forty cases of diphtheria at Epping. The only water to be had in outlying parts of the parish was obtained from ponds, which in many instances had become absolutely putrid during the drought in summer; samples of such water were green and opaque. Some fresh wells were immediately sunk, and the water-mains of the East London Company were extended to Chigwell-row. Great difficulty still exists with regard to the water-supply of the town of Epping.

Reviews and Notices of Books.

Louis Pasteur: his Life and Labours. By his SON-IN-LAW. Translated from the French by Lady CLAUD HAMILTON. London: Longmans, Green, and Co. 1885.

AMONGST all the eminent men assembled last year at Edinburgh to receive honorary degrees and take part in the ceremony whereby the University signalised its tercentenary, there was no one who was more enthusiastically welcomed than M. Louis Pasteur. It was a striking testimony to the appreciation of his indefatigable labours in the cause of science and humanity, work which has in so many directions overturned accepted beliefs, and has done even more in the way of opening up new and well-nigh inexhaustible fields of research. It is, then, with peculiar pleasure that we have read this record of his life, which shows how he was led from one point to another, and how the chemist was by reason of his chemical studies compelled to become in turn the biologist and experimental pathologist. The memoir is from the pen of M. Radot, the son-in-law of the *savant*, one who has lived long in intimacy with Pasteur, and, as he charmingly relates in the preface, whom he prevailed upon to be permitted to undertake the welcome task. And it is to Professor Tyndall that we owe the appearance of the English translation, which was entrusted to a most careful hand, of this "Histoire d'un Savant par un Ignorant," to which Professor Tyndall has prefaced an introduction that admirably surveys the whole theme. Pasteur's first great discovery was in chemistry—viz., the discrimination of the tartrates and paratartrates by the difference in their behaviour to polarisation; but, as Professor Tyndall shows, his generalisation from this discovery, as establishing a line of demarcation between the inorganic and organic kingdoms, has not been verified. It was, however, in the studies of the properties of the tartrates that Pasteur was led to his greatest discovery of fermentation being due to the action of living organisms—a discovery from which so much has issued, not only in the interpretation of chemical processes, but in those of the living body in health and disease. It is impossible yet to say how far-reaching that law of fermentation is, for from it have flowed all the researches upon morbid germs and infective disease, which daily multiply in number. Pasteur's own life-pursuit was dominated by the ideas that arose from the facts which replaced for chemical phenomena the fact of the intervention of living organisms. Hence he was engaged in the now historical controversy with the naturalist Pouchet upon spontaneous generation—a controversy which has been so completely settled that it is now almost forgotten. It was a curious thing that the chemist should have had to contest the truth of the doctrine that living things can only arise from life, whilst the biologist was contending that inert matter could become endowed with attributes of vitality; but the whole question turned upon delicacy of experimentation and accurate deduction from such experiment, and no wonder that the victory remained with the former. But this controversy was but an incident in the life of the experimentalist. His studies on the diseases of wine and of beer, resulting in simple measures for ensuring the purity of these articles, did much for commerce, but most of all in its direct practical utility was the issue of his prolonged and patient labour in unravelling the causes of silkworm disease, which threatened a whole industry. The description of his work on this subject is as readable as a romance, and the gratitude of France was well earned. It was on the completion of this work that Pasteur was attacked with paralysis, but, happily for humanity, he regained his health and resumed his researches with unabated energy. Splenic fever, septicæmia, fowl cholera, the discovery of the vaccine of splenic fever and its practical application,—these and other researches alone would make his name famous. Throughout it all he has met with opposition, but his opponents have almost invariably had to admit they were in error. Even upon the question of anthrax vaccination, which Koch assailed, the issue of the controversy has been, not to invalidate the efficacy of such protective inoculation, but only to place a limit upon its period of protectiveness. It is to be deplored that the author of the memoir should have done Koch such scant justice; for it is doubtless true that it was his researches upon the bacillus of anthrax that stimulated Pasteur to study the subject. The work to which Pasteur has been devoting himself for the past two years—namely, the prevention of hydrophobia—forms the subject of the last chapter of the book, which closes with an anecdote describing Pasteur summoned to see two dogs in the last stage of the disease. One, a large bull-dog, was secured to the bars of the iron cage in which he was kept, and there "the dog, suffocating with fury, his eyes bloodshot, and his body convulsed with a violent spasm, was extended upon a table, and held motionless, while Pasteur, leaning over his foaming head, at the distance of a finger's length, sucked up into a narrow tube some drops of the saliva. In the basement of the veterinary surgeon's house, witnessing this formidable *tête-à-tête*, I thought Pasteur grander than I had ever thought him before."

OUR LIBRARY TABLE.

Cruise of the "Alert": Four Years in Patagonian, Polynesian, and Mascarene Waters (1878-82). By R. W. COPPINGER, M.D., Staff Surgeon, Royal Navy, C.M.Z.S. London: W. Swan Sonnenschein and Co. — Naval surgeons on foreign, and especially on tropical, stations have ample opportunities for making valuable original researches in various departments of natural history, and the number of those who have availed themselves of such opportunities is considerable. When it was decided by the Admiralty to send out a vessel to survey the Straits of Magellan, certain doubtful reefs and islands of the South Pacific, and part of the northern and western coasts of Australia, Dr. Coppinger was specially selected for the medical charge on account of his knowledge of and interest in natural history. The volume before us embodies the results of his observations, related in a pleasant and interesting account of the voyage. Though the work can only be fully appreciated by an accomplished naturalist, it is full of interest to the general reader, and contains, scattered here and there, several valuable anthropological and medical facts which are specially interesting to the members of the profession. For example:—"We arrived at Talcahuano, one of the most interesting of the Chilian ports, on the morning of the 20th of April, and were surprised and grieved to hear that a severe epidemic of small-pox prevailed at the town of Concepcion, some nine miles inland. The epidemic had begun in January, and we were informed by Mr. Elton, the British Vice-consul, that since then no less than 1500 deaths had occurred, the mortality of those attacked having been at the extraordinarily high rate of 90 per cent." Of some aborigines he saw on the N.W. coast of Australia, Dr. Coppinger says:—"The nose was aquiline, with broad alæ nasi, and having the septum perforated for the reception of a white stick like a pipe-stem; the upper lip, cheek, and chin were furnished with a moderate growth of hair; the teeth were regular—no incisors removed; trunk and extremities almost devoid of hair; the skin of the arms, chest, and abdomen, was decorated with cicatrices, which stood out from the skin in bold relief, having the form and consistency of cords. On the arms these scars were disposed in parallel vertical lines, while on the chest and abdomen they were in horizontal curves. Dr. Morice informed me that these ghastly decorations were produced in some way unknown, by means of a sharp-cutting instrument, and that no foreign substance is introduced into the wound. He had been unsuccessful in all his efforts to ascertain how the peculiar raised and indurated character of the sore is produced." The question here propounded may perhaps be regarded as worth attention by pathologists. The work is well printed and well got up, and contains many good illustrations. If a map could have been included, the intelligent perusal would have been greatly facilitated, as few persons know much of the geography of the places described, and even a good ordinary atlas affords but little of such information.

Injuries of the Spine and Spinal Cord. By HERBERT W. PAGE, M.A., F.R.C.S. Second Edition. London: J. and A. Churchill. 1885.—When Mr. Page's book first appeared we noticed it at some length. The first edition has been soon exhausted, and Mr. Page has been well advised in republishing it. The changes and alterations in the edition before us are not numerous, and the additions are few and not very important. We deem it unnecessary, therefore, to deal at length with the present volume, but we may repeat that it contains a valuable amount of information on the subject upon which it treats. The amount of matter in the present volume is as nearly as possible the same as in the last, but the size of the page and of the type has been slightly reduced, and the weight to hold in the hand while reading has been greatly lessened. This is a gain which authors are too apt to make light of in the present day.

The Student's Guide to the Medical Profession. By C. B. KEETLEY, F.R.C.S. Second Edition. London: Baillière, Tindall, and Cox.—To the second edition of this work additions have been made which more than double the size of the book. They include chapters on Drawing, on Student's Societies, on Provincial Schools, on Scotch and Irish Schools, on the Army and Indian Medical Services, on Lunacy Work, and other important subjects. Considerable pains must also have been taken to collect the information given in the chapter entitled "The Conditions under which Pupils are taken at the Provincial Hospitals." In the list of the several legal qualifications and honorary degrees obtainable, including the minimum qualification to practise (given on p. 17), we notice one serious omission: the diploma of L.R.C.P. Lond. is not mentioned, an error which will doubtless be rectified in another edition, which will probably be soon called for. The work supplies a need, and can be consulted advantageously by all who intend to devote themselves to the practice of medicine.

Archives Italiennes de Biologie. Tome VI., Fasciculus 2.—This number contains the following articles:—1. Clinical and Physiological Researches on Paraldehyde, by V. Cervello. 2. On the Physiological Action of Antipyrin, by F. Coppola. 3. Perimetry and Self-registering Perimeters, by L. Ferri. 4. On the Action of Common Salt on Cercaria and their Desiccation, by E. Perroncito. 5. On Cicatrisation of Wounds of the Kidney, and on the Partial Regeneration of that Organ, by G. Pisenti, with a plate. 6. On the Presence of Albumen in the Saliva and Bile of Albuminuric Patients, by M. Dessalles. 7. Researches on the Air-sacs of Birds, by E. Ficalbi. 8. On Numerical Anomalies of the Semilunar Valves, by G. Martinotti and G. Sperino. 9. On the Microphytes of the Normal Human Skin, by G. Bizzozero, with a plate. 10. On the Organ of Corti in Monkeys, by A. Tafani, with eight figures in the text. 11. Notes on the Anatomy of the Negro, by G. Giacomini, with two plates and three figures in the text.

Transactions of the American Ophthalmological Society. Boston: Published by the Society. 1885.—This volume contains an interesting record of the following cases:—Hysterical Monocular Blindness with Violent Blepharospasm and

Mydriasis, by Dr. Harlan; Neuro-retinitis with almost sudden Loss of Sight in both Eyes, by Dr. Knapp; Hereditary Atrophy of the Optic Nerves, by Dr. Norris; Myxo-sarcoma of the Orbit and Osteoma of the Orbit, by Dr. Norris; Glioma of the Retina, by Dr. Little; Myxœdema with Atrophy of the Optic Nerves, by Dr. Wadsworth; Multiple Colobomata of the Iris, by Dr. Mittendorf; Hypermetropia passing into Myopia, with symptoms simulating general Nervous Disease, by Dr. Risley.

Analytical Records.

[WE think it right to direct attention to the system we adopt in the conduct of this department. Of the numerous articles of food and medicine submitted to us for analysis we select such as we think important to the medical profession and the public. Samples of these are bought by us in the ordinary way, and the results of our examinations reported.]

CARNRICK'S PEPTONISED COD-LIVER OIL AND MILK.

(MALTINE MANUFACTURING COMPANY.)

THIS is an exceedingly perfect emulsion of cod-liver oil and condensed milk, the oil-drops appearing under the microscope no larger than the granules of wheat starch. When the oil and fat are removed by ether and a drop of potash, a liquid remains which coagulates with acetic acid, and is evidently modified casein. This emulsion shows no tendency to separation. It has little of the disagreeable taste of the oil, and will be taken with ease by many who cannot digest pure oil. It is certainly a valuable and trustworthy preparation.

KING'S WHEATEN FLOUR FOR INFANTS.

(ALBION FOOD MILLS, SYCAMORE-STREET, E.C.)

This preparation is described on the wrapper as "prepared solely from the finest wheat," and is stated to be "free from any chemical additions." So far our analysis confirms the description. But when it is added that the flour is "thoroughly cooked by a new and improved patent process," we confess ourselves puzzled, for a great part, if not all, of the starch is ungelatinised. We notice that in the directions for use the addition of boiling milk or water is insisted on. This, of course, amounts to cooking.

BROWNING AS A SCIENTIFIC POET.

ON Friday evening, April 24th, Mr. Edward Berdoe, M.R.C.S., read a paper at University College, Gower-street, before the Browning Society, on "Browning as a Scientific Poet." The paper opened with an exhaustive argument to prove that the progress of science need not, as some had said, tend to the destruction of the poetic art; that, in fact, some of the greatest poets had enriched their verse by the study of natural phenomena—Lucretius, Haller, Milton, and Goethe, and in our own times Tennyson and Browning, while students of natural and physical science had not found their exact acquaintance with natural laws impede the luxuriant growth of their poetic fancy. In fact, to interpret Nature faithfully, she must be approached by a mind neither wholly scientific to the exclusion of reverence, nor wholly poetic to the exclusion of knowledge. Many of Browning's most beautiful similes were the result of his intimate acquaintance with anatomy, physiology, and chemistry; and the use he constantly makes of figures drawn from the science of optics has enabled him to illustrate his favourite optimism by much beautiful imagery. Tyndall claims for the scientist that "his imagination does not sever itself from the world of facts," and the poet of the future will be denied the former "power of dealing capriciously with facts," but this, Mr. Berdoe argued, would not oppose the [illegible] spirit. In the poem "Easter Day" Browning seemed to have anticipated by five years Herbert Spencer's theories of the evolution of the first rudiments of nerves in Medusæ along the lines of least resistance, as the following lines seem to show:—

> "Thy choice was earth; thou didst attest
> 'Twas fitter spirit should subserve
> The flesh, than flesh refine to nerve
> Beneath the spirit's play."

Tyndall's suggestion, that two-thirds of the rays of the sun fail to arouse in the eye the sense of vision because of its present imperfection, affords Browning, in "Jochanan Hakkadosh," an argument against the assumption that our reason is sufficient for the complete comprehension of the great problems of life, the soul, and God. Browning's splendid rehabilitation of the character of Paracelsus should earn him the gratitude of the medical profession. The poem may fitly be called the "Epic of the Healer." He speaks as lovingly of the human hand as Sir Charles Bell, and rebukes those who refuse belief in God because they cannot find Him with their microscope and scalpel:

> "The name comes close behind a stomach cyst;
> The small becomes the dreadful and immense."

"You cannot find soul?" he asks. "Show me an atom! You cannot believe in immortality? But an atom is immortal! You want scientific faith? It is absurd—would not be faith. Do you understand gravitation? The exhausted air-bell of the critic leaves no air to poison, and none to breathe." His Göttingen Professor, in "Easter Day," reduced the Pearl of Great Price to powder for purposes of analysis. Sweep it, then, to the dust-hole? No! religiously preserve the remains! This is what modern Agnosticism and Comtism is doing with Christianity.

Mr. Berdoe, in conclusion, claimed for Mr. Browning that he is essentially the poet for the scientific man; abreast of the highest culture of his time, in close touch with the great aims of science, he knows its limits, and tells us we may

> "Confidently lay to heart, and lock in head our life long this—
> He there, with the brand flamboyant, broad o'er night's forlorn abyss;
> Crowned by prose and verse; and wielding, with Wit's bauble learning's
> rod.
> Well? Why, he at least believed in Soul, was very sure of God!"

THE UNIVERSITY OF DURHAM.

To the Editor of THE LANCET.

SIR,—May I be allowed to make one or two corrections in regard to the notice of the Durham University given by your Northern Counties correspondent in your issue of the present week? 1. No alteration has been made in the regulations which have for several years been in force with respect to the Preliminary Arts Examination. 2. No alteration has been made in the regulations affecting candidates for the Final Examinations for the degrees in Medicine, nor in those which concern the one year's "residence," or attendance on lectures and hospital practice. 3. The curriculum, &c., for the licence in Medicine have for many years past been identical with those for the degrees in Medicine; thus the licence has for a long time been merged in the degree, in fact, since the necessity for the possession of an Arts degree, or its equivalent, by candidates for the degrees in Medicine has been done away with. 4. The alterations which were made in Convocation (not "convention") in the University on April 11th consist in a rearrangement of the subjects of the earlier portion of the curriculum, and are briefly as follows, viz.: (a) Instead of a single First M.B. Examination in Anatomy, Physiology, Chemistry, and Botany, there will be two examinations, the first including Elementary Anatomy and Physiology, Chemistry, Chemical Physics, and Botany; the second (intermediate) including Anatomy, Physiology, Materia Medica, and Pharmacy (the last two subjects being removed from the Final Examination altogether). (b) The First Examination of the Conjoint Board in England of the Royal Colleges of Physicians and Surgeons will be accepted in lieu of the First Examination of this University, except in regard to Chemistry; and the First and Second Examinations of this University will be accepted by the Conjoint Board in place of the First and Second Examinations of the Boards. These are the only alterations which have been made. I am, Sir, yours faithfully,

LUKE ARMSTRONG, M.D.,
Registrar of the University of Durham
College of Medicine.

University of Durham College of Medicine,
Newcastle-on-Tyne, April 28th, 1885.

THE LANCET.

LONDON: SATURDAY, MAY 2, 1885.

The meeting of the General Medical Council approaches, and is likely to be one of more than usual importance to medical students of the future. There is one consideration which may tend to liberate the Council in its discussion of proposed alterations in its Recommendations, whether as regards Preliminary Education or the Final Examination of medical students—namely, this: the supply of medical students is so ample, so much in excess of what is required to meet vacancies in the profession, that the regulations affecting both education and examination will bear to be much strengthened before any risk is run of starving the profession or leaving the public in that plight feared by Sir Lyon Playfair, when the sick will not be able to have a physician on account of the scarcity of that craft. We have before us the Medical Students' Register for 1885, and amongst its multifarious contents of interest to those concerned in medical education is a table giving the number of medical students registered last year, and for every preceding year since, and inclusive of, 1864. We may explain, for the benefit of our older readers, that no medical student can be registered as such until he has passed a Preliminary Examination, as required by the General Medical Council, and has produced evidence that he has commenced medical study. The numbers, therefore, which we are about to give are of those who have succeeded in passing one of the Preliminary Examinations of the fifty or sixty bodies recognised by the General Medical Council. We may remind our readers that the natural waste of the profession by death is under 600. If to this we add another hundred as representing those whose deaths have not been reported to the Registrar, or who, not having died, have retired or in some way dropped out of the Register, we may have some idea of the numbers required to keep up the present supply of medical men.

The number of medical students registered in 1884 was 1957, as against 1783 in 1883, and 1862 in 1882. If we divide the period of twenty years into four periods of five years each, we get the following as the average number of medical students annually beginning their curriculum: From 1865 to 1869 inclusive there was an annual registration of 908 students; from 1870 to 1874 inclusive, of 1263 students; from 1875 to 1879 inclusive, of 1643; from 1880 to 1884 inclusive, of 1975. Thus it appears that there is an increasing rush towards the medical profession. The rush is not quite steady and regular. Three or four years ago the annual number for two or three years was a little more than it was last year. But, dividing the periods quinquennially, it is clear that a great increasing number of youths look towards the profession as a calling. No doubt many of them never succeed in getting a qualification. From failure in examinations or in fortune, from defective ability, or, much more commonly, defective industry, they do not reach the goal for which they set out, and they either fall out of the profession altogether, or hang on to its skirts in the unsatisfactory form of unqualified assistants. The point of this interesting table, carefully made up by Mr. Miller, is that the Council has 1975 students a year to legislate for, and that it does not need half that number of students to be qualified annually in order to keep up the waste of the profession. We do not approve of the favourite pastime of the Council—that of always considering and altering the regulations of preliminary and medical education. It is exceedingly harassing to students and inconvenient to schools and teachers of medicine. Moreover, it does not tend to raise the Council in the respect of either students or teachers. But as there seems an intention to deal at the approaching meeting in some radical and serious way with fundamental principles in regard to preliminary and medical education, it is well to know that without any risk both the preliminary and final tests can be made more severe. If men are to be arrested in the process of entering the profession, the sooner the better. "Had it been early, it had been kind," might many a man say who is allowed to advance only so far in a medical career as to discover his unfitness and incompetency when it is too late. If the preliminary tests were of a thoroughly satisfactory kind they would tend greatly to diminish the subsequent rejections. We repeat, if a man is to be rejected, the sooner the better, and better in the preliminary stages than in the advanced ones. There is so much competition nowadays for students, such a rivalry of schools and examining boards, that there is constant danger of the Medical Council, in which school and examining board "interests" are so excessively represented, forgetting the great interests of the public and of the profession. We have shown by the Students' Register that there is no excuse for laxness of examinations on the score of defective supply of students, but, on the contrary, every encouragement to carry higher the standard of preliminary and medical education.

◆

It is much to be regretted that the Earl of Shaftesbury, whose name can never be mentioned in connexion with lunacy without the highest respect, has not found it possible to accept the principle of magisterial authority for the incarceration of a "lunatic" in an asylum, and rather than do so has resigned his position as Chairman of the Board of Commissioners. We attach the greatest moment to this new mode of procedure, and believe it will be found to afford a better safeguard against abuses than even its promoters anticipate. Altogether the Bill before the Lords is an admirable measure. The Earl of Milltown, who has already done so much real service in this matter, and to whose efforts we mainly owe the fact that the subject has been seriously taken in hand by the Government, did not speak too warmly when he complimented the Lord Chancellor on "the ample way in which he had fulfilled the promise he had made last session." If the Earl of Selborne will only consent to modify a few of the minor points in the scheme as drawn—for example, shortening the period during which an alleged lunatic may be confined on an emergency certificate, and compelling the Commissioners to carry out their examination *before* they chance to find it "convenient" to do so, the reform effected will be such as to render the law of lunacy in the main satisfactory. As to the private asylums, we think matters will adjust themselves before long. Those houses which are actually needed will be maintained; but the provision made by the county authorities will soon be sufficiently great to meet all ordinary demands, and the cheaper sort of "licensed house" will cease to be a profitable speculation. It is a most satisfactory feature of the reform to be effected by this Bill, that committees of public asylums will be able to ease the burden on the ratepayers by receiving private patients. This provision will tend greatly to encourage the gradual replacement of private by public asylums, which is so much desired. At the same time, it must not be forgotten by the Lord Chancellor, and we are sure the Earl of MILLTOWN will not lose sight of the fact, that as soon as they begin to take in paying patients, the committees of public asylums will themselves become "keepers of private asylums." This is a very important consideration. It must not be assumed that committees are immaculate. At this moment some of the larger private asylums are managed by committees composed of men whose social position is such as to inspire the highest confidence, and yet, in spite of this, the allegations of undue detention in these very asylums are fully as many and as damaging as any which have been brought against the proprietors of the smaller licensed houses. We are not making this statement without reason. It follows that the provisions of the Bill should be strengthened in regard to the reception of lunatics under emergency certificates. It was stated in evidence before the Select Committee of 1876, and we are still prepared to maintain the statement then made, that even forty-eight hours in a lunatic asylum may suffice to convert excitement in a neurotic subject into actual mental derangement which may afterwards resist all remedial efforts. Therefore we contend that the folly of allowing a patient to remain a month or more, or even *seven* days, without examination by a competent and impartial authority stands confessed on the face of the proposal. The next stage of the Bill is fixed for a fortnight hence. Let us hope that in the meanwhile the Lord Chancellor will see the wisdom of amending the faulty details of a measure which in principle, and as far as it goes, is as satisfactory as could be expected or desired.

◆

OUR readers are well aware of two things in reference to medical education in the United States. First, that it has hitherto been conducted on very free and easy principles, and, secondly, that earnest efforts are being made by good men and true in all the States to abate the scandals of medical education, and to bring it under some public and responsible authorities comparable with those which regulate it in all other civilised communities. An instructive prospectus on this subject has just been issued by the Illinois State Board of Health, with the help of which we shall try to elucidate for the benefit of our readers the real condition of things in the States, not so much with the view of finding fault as of supporting and helping those who endeavour to bring about a better state of things. The Illinois Board of Health proceeds under an act of the State called the Medical Practice Act, and publishes a schedule of minimum requirements. Diplomas from colleges which give evidence of an actual and *bona fide* compliance with this schedule are accepted unconditionally. Diplomas from those which do not are required to be supplemented by an examination before the Board on the branches or subjects of the schedule omitted by the colleges in question. The schedule requires—1. Certificates of moral standing. Diplomas of graduation from a good literary and scientific college or high school; failing this, a thorough examination must be passed in mathematics, English composition, and elementary physics or natural philosophy. 2. Instruction in ten subjects or branches of medical science. 3. The length of regular or graduating courses or sessions to be five months, or twenty weeks, each; and two full courses of lectures, not within one and the same year, are required for graduation with the degree of Doctor of Medicine. 4. Regular examinations are to be made by each lecturer daily, or twice a week at least, and final examinations, where practicable, by competent examiners other than the professors in each branch. 5. Dissections and hospital practice during two terms. 6. The time of professional studies to be not less than three full years before graduation. 7. Each college must show that it has a sufficient and competent corps of instructors and facilities for teaching.

Such is the standard of medical education in one of the States which have confided the regulation of medical study to a Board of Health. It will not be thought exacting in its demands. But of 47 colleges which have claimed to have their diplomas recognised by the Board, only 26 were found to have regulations satisfying its requirements. The state of medical education in the United States is one of the illustrations of the disadvantage of a strong central government. Each State is a law to itself, and in many States it seems possible for any group of needy or adventurous physicians to form themselves into a medical school—otherwise a diploma-mill. The extent to which this evil has attained may be gathered from the fact that a total of 234 different medical institutions are given in a list in this pamphlet, dating from the year 1765. There are now in existence no less than 128 such bodies. Excluding 12 in Canada, there remain 116 in the United States, which for 38 States gives 3 per State. Among the extinct schools there are 54 out of 153 regular, 7 out of 20 homœopathic, 12 out of 24 eclectic, and 6 out of 10 physio-medical and miscellaneous. Out of 18 fraudulent institutes, 17 happily are now extinct. The "Boston Bellevue" is the only one of this class remaining. These figures are very significant. They show the mushroom-like growth and death of these "colleges." The harm done by them is incalculable. The competition engendered makes it very difficult for the more organised and recognised schools to maintain a high standard. The most absurd particulars are given of the devices resorted to for catching students. Personal solicitations, low fees or no fees, and the certainty that a diploma may be obtained on a minimum of knowledge and education, general or medical, are all enlisted. We are threatened in this country with a form of Parliamentary government where freedom may be prized above knowledge and efficiency; but we have not yet reached this depth, and we can only wish our American friends a speedy curtailment of that form of liberty which permits the creation of an indefinite number of schools to issue diplomas legalising the ignorant practice of an art in which a little knowledge is verily a dangerous thing. There is some hope of this consummation on two grounds. First, the public is deeply interested in the suppression of mere diploma-mills, and in the quality of work done at medical schools; and, secondly, the evil now felt by the medical profession was formerly rampant in the legal profession in New York. Idle and incompetent young men were admitted to the bar in excess of legal business and the legitimate increase of the profession. The Higher Courts took measures to restrict the supply, and ordered that only graduates of certain specified law schools should be eligible for examination after a certain date. The other law schools closed their doors. The profession upheld the courts, and the end was gained. Let medicine take a hint from law. It is only fair to say that there are signs of improvement in the standard and methods of medical education in the States, of which the following are the most important: 102 colleges now exact a matriculation examination, as against 45 in the first Conspectus of the Board of Health; more colleges are requiring longer courses of lectures, and making provision for what are called "graded" courses—i.e., courses which are not mere repetitions of previous courses, but developments of them. We must leave this subject with every expression of sympathy with those who are seeking to abolish fraudulent medical schools and diplomas.

◆

Some incidental remarks made at a recent meeting of the Pathological Society revealed the existence of the first genuine instance of Actinomycosis in this country. The case occurred, we believe, in the practice of Dr. Harley at St. Thomas's Hospital, the post-mortem examination being made by Dr. Sharkey, and the microscopical examination by Mr. S. G. Shattock, curator of the museum. As the disease in man has only been recognised within the past decade, and as no cases have hitherto been recorded in this country, it is not surprising that but few members of the profession in England should be acquainted with it. A valuable clinical contribution to our knowledge of the affection in man has recently appeared from the pen of Dr. J. Israel.[1] In 1882 Professor Ponfick published an almost exhaustive monograph on the disease, in which most of the facts then known were embodied. From questions which have been addressed to us, we believe that a brief account of the elemental features of the affection will be welcomed by the majority of the profession, to whom the malady is unknown.

The affection is presumably one which is dependent on the presence and activity of a micro-organism. The microparasite is a member of the fungoid class, and consists chiefly of a mycelium which divides in a dichotomous fashion, and gives rise by its spread from a centre to a radiate appearance, whence its name—actinomyces—is derived. The circumferential ends of the mycelial sprouts have a flask-shaped swelling. The little masses of felted mycelium may be recognised by the naked eye as sulphur-yellow bodies of about the size of a hemp-seed. The disease which this parasite is supposed to cause may develop in many parts of the body. The most common site appears to be the jaw and parts bounding the mouth. The affection in animals has long been known in this situation under various names, and has been regarded as a form of scrofula and as a new growth. It is believed that the parasite gains an entrance through the medium of a carious tooth or some wound of the gum leading to the jaw-bone. There is but little to be said of the morbid anatomy of the disease. A swelling forms in the jaw, and gradually increases in size. This tumour in its earliest stages may be punctured without any matter being let out, although it generally has an elastic and semi-fluctuating consistence. A section made into a tumour in the early stage of its existence shows a reddish-white area sprinkled in places with gold-coloured granules. Later on abscesses and fistulæ form, in the discharge from which the sulphur-coloured bodies may be seen. Broadly speaking, the tissue of the morbid new growth, which must be regarded as inflammatory rather than sarcomatous, has very much the characters of ordinary granulation tissue. Actinomycosis may occur primarily in the respiratory tract proper, and Dr. Israel makes this class of cases his second group. He narrates a case in which the disease was localised to the bronchial mucous membrane. The patient was a girl aged fifteen, who suffered from the signs and symptoms of chronic bronchitis, with fetid expectoration, in which the actinomyces were readily discovered. Another case of a man, aged twenty, is given, in which the primary localisation of the disease was in the parenchyma of the lung; it was afterwards propagated to the pleura and to the prævertebral tissues. Some of the cases have many of the clinical characters of empyema with discharging sinuses, and in such cases a complex system of fistulæ not unfrequently undermines the morbid tissues. The structures in the posterior mediastinum and prævertebral regions are often affected, and the bodies of the vertebræ may become carious. Dr. Israel makes his third group of cases include those in which the disease begins primarily in the intestinal canal. In some of the cases the foci of the disease are widely disseminated. The liver, spleen, muscles of the back, and muscular substance of the heart have been shown on post-mortem examination to have numerous centres of actinomycosis. Large abscess cavities may form behind the peritoneum as well as behind the pleura, and these may communicate by many perforations of the diaphragm. The symptoms necessarily depend chiefly on the localisations of the disease as well as on its rate of progress, and present therefore extremely varied clinical pictures. Dr. Israel's work contains an account of thirty-eight cases, which number includes all that have hitherto been recorded.

A meeting of graduates of the Royal University of Ireland, including members of the Parliamentary Committee of the Senate and of the Council of the Graduates' Association, was held last week in the Westminster Palace Hotel, presided over by Sir William Mac Cormac. It was resolved that steps should be taken to press the claim of the University to Parliamentary representation, and a special committee was appointed to carry out the necessary arrangements. This committee will include Sir William Mac Cormac, and Drs. Knight, Jones, Purcell, MacKellan, Henry, Huggard, and Wheeler.

Dr. Mapother has resigned his seat on the Council of the Royal College of Surgeons, Ireland, and most probably will be succeeded by Dr. Hamilton.

Annotations.

"Ne quid nimis."

THE WAR IN THE SOUDAN.

THE experiences of our war correspondent in the Soudan will, we are sure, be read with much interest. They give a graphic description of the arrangements at the base for the sick and wounded of our troops, and furnish most gratifying testimony to the care which has been bestowed in making them, and to the intelligence and zeal with which they have been carried out. There were but two matters which did not seem to have been satisfactorily arranged, and, if we mistake not, for neither of these could the officers of the medical staff be deemed responsible. The first was the position of the burial-ground, which was very badly chosen, but after it was found to be a nuisance to the hospital ships it was closed and a new site selected. The other was the repetition of one of the great causes of complaint in the Crimea: the mixing up of the medical stores and hospital equipments with other goods, instead of having them either sent in a vessel specially retained for the purpose, or, at least, having them carefully separated when landed and arranged so as to be easily found when required. Our correspondent bears strong testimony to the admirable manner in which the officers of the medical staff have discharged their duties in the field, as witnessed by him in the disastrous affair of the 22nd of March, when the military commander allowed himself to be surprised, and to the very efficient arrangements for the treatment of the cases in the hospitals at the base. But he sounds a note of alarm on a subject to which we have already called attention the great risk to be incurred if the troops are kept in the Soudan during the ensuing months of intense heat. Not only is there the probability of a great number of cases of heat apoplexy and of dysentery, but there is the certainty of exhaustion of the vital powers through loss of appetite and deprivation of sleep, which must inevitably destroy the efficiency of the men. The subject is one which calls for the most anxious consideration of the military authorities, and for immediate action if anything is to be done to avert such a deplorable prospect. If any delay occur in coming to a decision on this point, we fear that the ultimate measures will be found to be "too late," as has already been so often the case in the conduct of this miserable expedition.

THE NATIONAL AID SOCIETY.

ATTENTION has lately been called in the daily papers to the proceedings of the National Aid Society in connexion with the campaign in the Soudan. There probably never was an army sent from this country so fully supplied with everything necessary for the treatment of the sick and wounded as the one now serving in the Soudan; nor was there ever one in which the arrangements for that purpose were so successfully carried out. There has been but one opinion expressed by those cognisant of the facts, and competent to judge of the results, and that is, that the work of the medical service in this campaign has been excellently performed, and that the wants of the sick and wounded have been abundantly supplied and their comforts fully attended to. Under these circumstances, it is difficult to understand on what plea the very considerable expenses incurred by the National Aid Society can be justified. The Government has provided most amply both a complete staff of medical officers, nurses, and orderlies, and an ample supply of the necessary medicines and medical comforts. To supplement these by private means is like carrying coals to Newcastle; and if a statement were published of the articles sent out by the Society, we have a strong suspicion they would be found to consist to a great extent of luxuries which it is simply absurd to provide for the class to whom they have been sent. The manner in which this Society keeps itself before the public in the columns of the newspapers would, if followed by any professional person, be put down as quackery of the most intolerable kind, and it is painful to witness the efforts made to gain notoriety for its leaders. If, instead of profuse expenditure in providing luxuries when they are not required, and when the needful comforts are already abundantly supplied by Government, the National Aid Society would turn its attention to the wants of the wives and children left at home, and to the assistance and comfort of the widows and orphans of those who have fallen in the unhappy and mismanaged conflict in the Soudan, they would be doing a work of kindness and charity which would redound to their credit, though perhaps it might not afford so good an opportunity of self-gratulation as the course now pursued. It is alleged in some of the papers that the Society has a large sum of money at its command, and that it has not published any statement of its accounts since 1871. We know not whether this be correct or not, but, if so, we think one of the first acts of Sir R. Loyd Lindsay should be to give an account of his stewardship, to show how much he has spent, how he has spent it, and to justify the course which has been adopted by the Society in supplementing a service which was already quite equal to the requirements. In our opinion it has done serious mischief in shaking the confidence of the soldier in those to whom he is entrusted, and in generating a desire—may we not say a demand—for things which are not only unnecessary but often injurious. We are most reluctant to place any difficulties in the way of showing kindness to our soldiers, but we think far more good could be done by making provision for their families and for those left behind, than in parading great preparations to supply artificial wants rose-water and eau-de-Cologne and blowing loud in the streets the trumpets of the leaders of this quasi-benevolent Society.

CREMATION UNNECESSARY AND INJUDICIOUS.

A PAPER read by Sir Spencer Wells at the Parkes Museum has brought again before the public eye the long train of arguments for and against cremation and burial, which we have shortly sketched in former articles upon this question. Some would tell us that there is no longer any question as to the preference to be accorded to urn-burial. Despite the tendency of the late discussion, which was so far an apparent success for the advocates of the newer method that it was almost entirely one-sided, we venture to think that there is still room for much difference of opinion. On sanitary grounds, we can well see how objection may be raised to the continuance of a custom even so long approved, when ignorant malpractice or gross neglect of natural methods have turned the earth of the graveyard into a reeking pit of huddled corpses. Sir Spencer Wells makes much in his paper of certain spots of this kind discovered in Ireland. He regards as impracticable the scheme of the Local Government Board for the better laying out of cemeteries; and he places in contrast with the foulness of ill-conducted burials the refined and classic purity of cinerary urns. These comparisons are within the usual limits of persuasion, but it does not follow that they present equally to the mind both sides of the question at issue. We do not think that the abuse of burial in the earth justifies its abolition, any more than the Indian suttee represents or bans the practice of cremation. It is easy to bury decently, and yet to bring the human clay to earth in a more than figurative sense. If this were done, as it may and ought to be, no objection which is not purely theoretical and unproved could be urged against it. Decomposition would be allowed and aided, and all communication between the areas of burial and those inhabited by the living could be prevented by appropriate drainage and isolation of soil. The rule and habit of Nature, by which she constantly and faultlessly removes and uses all dead creatures not consumed as food—namely, absolute surrender to the elements—would suffer no further change than that of somewhat retarded action, a change which frequently marks without marring her efforts in this direction. It is idle, therefore, to talk of so many million corpses having to be strewn over the country in a single generation. Long before the end of half that term the buried dead, if not pulverised by decay, would have ceased to yield sustenance to the germs of mortal change. The medico-legal aspect of cremation has been so often discussed that little remains to be said about it. The recent combustion of a body at Woking, it is important to note, was preceded by an autopsy. The necessity for this precaution, and the further analyses to which it may give rise, are not likely to weigh greatly as objections with those who contemplate the future incineration of their bodies. Post-mortem examination offers but trifling violence to the person in comparison with the fire of the crematorium. However this may be, it is clear to our minds that no less decisive measure can compensate the criminal law for the loss of the evidence of fact which it must otherwise occasionally sustain in the total destruction of the dead by fire.

BULLYING AT SCHOOL.

The death of a little boy, aged twelve years, through injuries received from blows on the spine from a dozen or so of the bigger pupils at King's College, has led to an inquest, with a verdict of "Death by misadventure," the jury adding the following rider: "That the attention of the authorities at King's College should be called to the evident want of supervision over boys during the interval of school hours, which, in the opinion of the jury, led to the death of Charles Fisher Bourdas." The coroner, in summing up, strongly deprecated the rough play that prevails in almost all schools. We have good reason for stating that the cruelty of bigger boys to little boys is not confined to "rough play," but that a system of bullying prevails out of class hours, of which the masters at schools are as ignorant as the head master of King's College, in his evidence, admitted himself to be of the cruel practices of his own pupils. When the work of the class is over the form master turns his pupils loose, and considers his responsibility at an end. There is always a strong resistance exhibited by the form master against an attempt on the part of the head master or the governing authority to impose on him any responsibility for the conduct of his pupils out of class. Indeed, the governing authority of a school is a nonentity in matters of discipline, and it rests with the head master to make the best arrangement he can for the good conduct of his pupils in the intervals of class. As a rule this duty is imposed on the senior boys or prefects of the school. The head master, as well as assistant masters, usually, are intentionally ignorant of the methods adopted by the elder boys of the school to maintain, out of class, discipline among the younger pupils. The strictest secrecy is preserved, and no point of schoolboy honour is more rigidly maintained than the principle of not "splitting" either to masters or friends. In fact, so rigidly is this observed among most schoolboys that if masters institute an inquiry the schoolboy code of honour not only justifies him in suppressing the truth, but even in telling a lie to screen his school companions. It is, therefore, exceedingly difficult for the head master to become acquainted with the practices of his school, and the ignorance displayed by the head master of King's College in this respect is no more than prevails among all head masters. This, nevertheless, is no justification of the grave defects of discipline which lead to cruelty and oppression of the weaker and younger boys. Something more is wanted than mere prefectorial supervision, the authority of which has to be maintained by harsh and unfeeling treatment, accompanied often by cruel blows and kicks, or, as at one of our public schools, by "bending" a lithe ground ash stick across the back of the poor little culprit.

THE CUSTODY OF LUNATICS.

"Let the authorities get out of the difficulty as best they may." This is our advice to the medical officers of workhouses, and, so far as we have any influence with masters, to those officials also. It has long been a most mischievous practice to send suspected lunatics to workhouses, and to remand persons brought before magistrates to the same institutions on suspicion of insanity. A workhouse is not the place for such cases. As a matter of fact, a prison is better, if no more suitable place of observation can be found. The only right way out of the difficulty is to provide reception and probation wards in connexion with the public asylums for lunatics. This should be done at once, as we long ago suggested. We are not disposed to yield an inch of the ground we have taken up in regard to this matter, and we think it will be much to be regretted if the Local Government Board should give way under the pressure brought to bear upon it. The judge was right, the stipendiaries are wrong, and it is unfortunate that we have not a Home Secretary with sufficient strength of purpose to maintain the authority of the judicial opinion expressed.

THE PERILS OF FOOTBALL.

Now that the football season has come to an end, a timely opportunity occurs of drawing attention to the exceptional amount of danger run by the votaries of a much-abused (in every sense of the word) form of amusement and exercise. Since October last we have taken the trouble to cut out the record of each case of accident at football that we have met with in the papers, without, be it noted, any special search for them. The following is the result:—Oct. 10th: At Eton, Mr. W. J. C. "had his right leg broken by a cross kick."—24th: Mr. C., a student of St. Augustine's Missionary College, Canterbury, "had his leg broken."—25th: W. M'G., "while engaged in a match, was kicked in the stomach, but, feeling better afterwards, he finished the game. He died some time afterwards from internal injuries."—29th: Mr. W. P. G. "had his collar-bone broken."—Nov. 17th: W. A. "had his leg badly broken below the knee."—Dec. 1st: Mr. H. W. P.'s "left leg was broken clean through."—6th: Mr. E. G. B. "received a severe kick on his left leg, by which two bones were broken just above the ankle-joint."—13th: Mr. H. H. G., a well-known athlete, sustained an injury to his right ankle which, in sporting parlance, "effectually put a stopper on his engaging in those pursuits of which he was such a rattling exponent." On the same day, in one match, two players received injuries which compelled their retirement; in another the captain of one of the teams had his leg broken; in a third a fracture of the collar-bone occurred (in this last it is added, "the play is described as having been rough"); in a fourth, "one of the Flint men had his collar-bone broken through being violently charged by one of the opposing team."—16th: A broken leg.—22nd: Broken collar-bone.—27th: Broken leg and severe internal injuries.—29th: Fracture of right leg just above the ankle.—Jan. 5th: H. L. "received a violent kick in the stomach, which completely prostrated him and caused him intense n"; he died two days later from his injuries.—19th: A ayer "received serious internal injuries."—Feb. 2nd: Case f fracture of collar-bone.—9th: Two cases of fracture of ollar-bone and one of fibula.—March 9th: W. "had his ankle-bone completely broken by a kick."—30th: T. S. "was accidentally kicked in the face; his lips, nose, and cheek were cut, and he was removed to a hospital."—April 4th: Broken leg.—13th: Broken arm. In this case "the game is said to have been characterised by a good deal of rough play." This list, which of course in no way represents the total amount of the season's football casualties, amply suffices to recall attention to the exceptionally dangerous nature of the game. No other popular game with which we are acquainted has the same amount of peril attached to it. It may be urged that accidents are bound to occur in all sorts and kinds of amusement, and that hunting is responsible for even worse and more frequent accidents than football; this may be so, but hunting is free from the objectionable element of personal conflict which pervades football. The game requires reform; we say *reform*, because we think it would be unwise, and on the whole undesirable, to follow a recent American proposal, and demand its prohibition in our schools. To put a stop altogether to the principal winter amusement of thousands of young people would, we are sure, be impossible. Nor is it needed; for football, under such restrictions as would reduce the number and severity of these frequent accidents, is capable of far more good than harm. What those restrictions should be is not for us to decide, but we would venture to call the attention of the Rugby Union and the Association authorities to "collaring" and "charging" respectively. Reform there must be, for the game is still only too well described by an old writer as "a friendlie kind of fight rather than a play or recreation—a bloody and murthering practise than a felowly sporte or pastime."

SANITARY PROGRESS IN COVENTRY.

Dr. Fenton's annual report for 1884 refers to the circumstance that his appointment has recently been made under the order of the Local Government Board. The occasion is opportune for giving a summary of the history of sanitary work in the borough during recent years. When the appointment of an officer of health was made in 1874 it was somewhat tentative in character. No means then existed for dealing with infectious diseases, some 2000 old-fashioned middens existed, well water liable to pollution by soakage of filth was somewhat extensively in use, the town water was in part derived from a stream which received sewage, and there was generally much carelessness and ignorance in sanitary matters. At the present date matters stand on a very different footing. Scavenging is done efficiently by the corporation officers, and it is in contemplation to erect a destructor; the offensive middens are largely done away with, only 200 of these structures remaining; the local wells have been, and are still being, closed; and the town water, which has been freed from the risk of contamination at its source, is replacing the former supply. Further, excellent hospital accommodation has been provided for cases of infectious diseases. First, a temporary iron structure was erected, and this, coupled with a voluntary system of notification, materially aided the authority in staying the spread of infectious diseases. Now, however, a modern hospital of two pavilions, with all needed administrative buildings, and a Ransome disinfecting stove, are available for the purposes of the urban district. Some practical outcome of this action may naturally be looked for, and it is forthcoming. In the five years preceding 1874, when the medical officer of health was first appointed, the annual death-rate from all causes and that from the seven principal zymotic diseases stood at [illegible] and [illegible] per 1000 respectively. In the five years ending 1884 the respective rates were 18·7 and 2·1—figures which indicate a large saving of valuable lives. In some towns officers of health were appointed, under statute, with much reluctance. Whatever may have been the case in Coventry, the authority of that town have now recognised the value of Dr. Fenton's work, and have, as the result of his efficient labours, placed his appointment on a higher and more satisfactory footing.

HEALTH OF THE POLICE.

The Report on the Health of the Metropolitan Police for the year 1884 has just been issued by the chief surgeon, Mr. T. Holmes. The force numbers over 13,000 men. The daily average loss on the whole force by sickness was 2·93, which is nearly identical with the previous year's rate. The total injuries were 1129—727 "on duty," 230 "not on duty," and 172 sore feet. The ratio of these to the total number of men is about the same as the year before. The diseases of exposure, chronic and muscular rheumatism, coryza, bronchitis, and tonsillitis, were 874, 631, 461, and 1007 in the four quarters of the year respectively; making a total of 2973, which is rather less, both absolutely and relatively, than in 1883. For venereal disease 22 were suspended, 14 of these being sent to the Lock Hospital. During the year there were only 6 cases of small-pox, 2 of which were doubtful or "modified"; all were slight. One hundred and sixty-four men were admitted into hospitals; these were chiefly distributed amongst St. George's, Westminster, St. Bartholomew's, Guy's, University College, the London Fever, and the Lock; besides which twenty-six men of the outlying dockyard divisions were admitted into naval hospitals. The number of deaths in the Town and Woolwich divisions was 47, of which 15 were referred to consumption and "disease of lungs," 4 to pneumonia and pleurisy, 4 to bronchitis, 3 to rheumatic fever, 3 each to apoplexy and heart-disease, 2 each to typhoid, erysipelas, acute nephritis, and diabetes, and 1 each to scarlet fever, pyæmia, tumour of brain, phlebitis, psoas abscess, cancer, and drowning. Besides those who died, 223 were removed from unfitness through age or disease.

EPIDEMIC OF MEASLES IN GUERNSEY.

A widespread epidemic of measles occurred in the Island of Guernsey during the last quarter of 1884, and it is the subject of a paper by Dr. J. Aikman in the *Glasgow Medical Journal*. The disease appears to have been imported from Jersey, to have been nurtured among the parish patients in the north district until it gathered epidemic force, and then to have spread to all classes of the population. It is explained that there are no data upon which to base any statistics with regard to the extent of the epidemic, but the local papers stated that there had been from 3000 to 4000 cases, in a population of some 30,000. Guernsey has been so free from epidemics for the past thirty-five years that it has been thought by some that local insanitary conditions must have been the cause of so exceptional a prevalence. The situation of its principal town on the slope of a hill, permitting the fresh aeration of even its narrowest streets by means of the sea-breeze from the Channel, and a sub-soil of gravel and granite, afford natural conditions in favour of healthiness. But fault is found with the method of sewer ventilation; and house-drains are in this respect probably far more in fault. The water-supply is from public and private wells, many of which are in proximity to buildings and are liable to accidental contamination. It is always difficult to determine how far measles is associated in its spread with faulty sanitary circumstances, and the fact that Guernsey had long been free from it, supplies an explanation of the extent of the epidemic by reason of the number of children and young persons who would have been susceptible to its influence. But whatever conclusion may be arrived at on this point, it is certain that the sanitary conditions to which we have adverted, and which are a blot on the reputation of a charming pleasure and health resort, should be at once remedied. We are glad to learn that a scheme is already on foot for supplying the town with a water which shall be free from suspicion.

THE APOTHECARY, ANCIENT AND MODERN.

THE peculiar position in which the Society of Apothecaries of the City of London has been placed by threatened legislation and by the new regulations of the Medical Council, has induced Dr. Corfe, the present Master, to sketch briefly the history of the Society, from the time of its foundation to the present time. Commencing with a cursory review of the rise and varied conditions of the body of men styled "apothecaries" during seven centuries (1180 to 1880), Dr. Corfe glances at the four stages of their history—viz., 1st, as Pepperers, of Soper's-lane, or Easterling's, trading with Egypt, Arabia, India, through Constantinople; 2nd, as a class becoming incorporated with the Company of the Grocers, but retaining their special title of apothecaries, and practising as such; 3rd, the disseverance of the fraternity from this company, and the establishment by Royal Charter of the present Society as an independent body; and lastly, the acquisition, by the Act of 1815, of the privilege of constituting itself as a Society for educational, examining, and licensing purposes. The remainder of the book is occupied with an account of the nature of the examination for the licence, a description of the hall and the articles of interest in it, a chronological glossary, and a list of eminent men who have been directly or indirectly connected with the Society. The work is intended, it is stated, to illustrate the facts—(1st) that the apothecary of the first and last portion of the nineteenth century is a coördinate practitioner with the same personage who carried on this profession in the twelfth century; and (2nd) that such persons were viewed as educated men, though traders. In another portion of the pamphlet, however, the author expresses the hope that he will be able to convince his readers of the great benefit which the Society has rendered to science, the advantages which it has conferred on the world at large, and the ability it still displays to carry on its functions for the good of mankind whilst it upholds its own reputation and the honour of the medical profession; and it may be fairly supposed that this is his main object.

ALLEGED CHOLERA VACCINATION.

CONSIDERABLE excitement has been aroused in Spain, both within and without scientific circles, upon the alleged discovery of protective inoculation for cholera; and we read that already numbers of people (300 according to one report) have submitted to inoculation with the choleraic "virus." In spite of the statements made by Dr. Ferrán (*vide* p. 489) we would venture to submit that the fact of such protective inoculation is by no means proved, if indeed it be capable of proof. For, so far as we know, cholera has never been transmitted by inoculation, and cannot therefore be placed on the same footing as small-pox, anthrax, and other diseases, in which the blood is apparently the seat of the organised virus. Nor can it be yet considered as determined that the microbe discovered by Koch is the specific cause of cholera. We have so recently heard this latter point discussed that there is no need to allude to it further; and it seems not only premature, but absolutely wrong, to promulgate the doctrine that cholera can be prevented by inoculation before these points are settled. The profession in Spain would do far more to protect their country from an epidemic if they urgently pressed on the authorities to undertake sanitary measures in the towns, than by lulling people into a fancied security by spreading the belief that inoculation will protect an individual from the disease. If cholera does visit Spain they will be wofully undeceived.

OVER-PRESSURE IN SCHOOLS.

DR. CRICHTON BROWNE'S letter in *The Times* a few days ago will be read with interest. He contends that the recent reduction in the rate of mortality among children, upon which Lord Aberdare laid great stress in his address at Manchester, is no proof of beneficial results from the effects of education; and he urges, on the other side, that disease and disturbance of the nervous system are increasingly frequent among the young. This is a fact which cannot be gainsaid. Headaches and nerve troubles of various descriptions are extremely prevalent, and we have no doubt that they are in great part the effects of brain work of a class and kind which is injurious to health, and will hereafter be found to be detrimental to progress. Mr. Mundella may try to sweep back the Atlantic with a broom, but, as Dr. Crichton Browne remarks, he must find better brooms than have yet been made available, Sir Lyon Playfair and Lord Aberdare not excepted.

VIRCHOW'S ARCHIV.

THE commencement of the one hundredth volume of the world-famous *Archiv für Pathologische Anatomie und Physiologie* is signalised by a few pages of retrospect by its illustrious editor, Professor Virchow. When he recalls the condition of medical science in 1847, the year of the first issue of the *Archiv*, and contrasts it with its position at the present day, he may well be pardoned any feelings of pride at the advances that have been made therein to which his *Archiv* has so remarkably contributed. He tells us that the enterprise undertaken by himself and B. Reinhardt was at the outset almost alone—at any rate in North Germany—in its object of promoting scientific research with direct application to medicine, and he pays a well-merited tribute to the encouragement and aid furnished by the publisher, G. Reimer, whose death at an advanced age occurred quite recently. The first numbers were almost solely composed of the contributions of the editors, and before the fourth volume was completed in 1852, the death of Reinhardt left Virchow alone in the editorial chair. But contributors were not lacking, and as years passed on they became so numerous that after the thirty-first volume (1864) the *Archiv* was issued monthly, forming three volumes a year; and in 1879 a further enlargement was found necessary, so that since that date four volumes have appeared annually. It would be quite possible to extend it still further, for the contributions are so numerous; but Virchow deprecates any further extension on the ground of cost. The statement speaks well for the great success and high reputation of the *Archiv*, which is read in all parts of the world. At first it was intended to confine its scope to subjects directly related to medicine; but it was soon found necessary to widen this area, with the result that its volumes contain much of the early work of anatomists, histologists, physiologists, and embyologists; and this in spite of the vast increase in scientific periodical literature that has taken place. In its pages may be found a complete history of the development of medical science; for it has fulfilled the object of its founders in making it a repertory of detailed observations to elucidate the problems of pathology. Prof. Virchow goes on to review this progress in one department with which his name is specially connected—viz., the application of the cell-doctrine of nutrition to morbid processes, and he clearly shows how the doctrine has been enlarged and elaborated in course of time. He alludes with sorrow to those amongst the contributors to the work who have since died, including Reinhardt, Leubuscher, Beckmann, Friedreich, Otto Weber, C. E. Hoffmann, Förster, Buhl, v. Wittich, Rudnew, Hüter, and Cohnheim, many of whom are famous in their writings, but whose earliest ideas found expression in the pages of the *Archiv*. Not a few of them were his own pupils, several were long engaged as his assistants, and in losing them he feels a pang as if a part of himself had been torn away. In a few words at the close of this article he expresses his confident belief that the work thus commenced will be carried on with the same earnestness and vigour, and that the history of the *Archiv* in the future will be as rich as it has been in the past. That it may be many years before it is deprived of the guidance of its founder is the earnest hope of all who reckon this as not the least of his many great achievements in the cause of science.

ASSOCIATION FOR PROMOTING A TEACHING UNIVERSITY FOR LONDON.

AN important Conference between the Executive Committee of the above Association and representatives of the London Medical Schools will take place at 4.30 P.M. on Monday next (May 4th), at the rooms of the Society of Arts. The following medical schools have chosen the gentlemen named to represent them upon this occasion:—St. Thomas's Hospital: Dr. Bristowe, Dr. Bernays, and Mr. Sydney Jones. Middlesex Hospital: Dr. Cayley and Dr. Coupland. St. Bartholomew's Hospital: Dr. Norman Moore, Dr. Dyce Duckworth, Dr. Russell, and Mr. Willett. University College Hospital: Dr. Barlow, Professor Schäfer, and Professor Berkeley Hill. King's College Hospital: Dr. Curnow, Professor Bentley, and Professor Gerald Yeo. St. Mary's Hospital: Dr. Sieveking. Westminster Hospital: Dr. De Havilland Hall and Mr. George Cowell. Guy's Hospital: Dr. Taylor, Dr. Stevenson, and Mr. Howse. London Hospital: Dr. Down and Mr. Treves. It is expected that the medical schools of St. George's Hospital, Charing-cross Hospital, and the Royal Free Hospital will also be represented at the Conference.

THE EXPLOSION AT THE ADMIRALTY.

MR. SWAINSON, who was injured by the explosion at the Admiralty, we are pleased to say continues to make satisfactory progress. The recovery of consciousness was accompanied by vomiting, which lasted at intervals until midnight. The wounds of the scalp are healing, there having been very little suppuration. The wound of the left conjunctiva was accompanied either by fracture of the lacrymal bone (no bone was, however, felt on probing) or wound of the nasal duct, as sudden emphysema of the upper eyelid followed an attempt to blow the nose on the day following the injury. There was no wound of the eyelids. The temperature has not exceeded 99°. There has been no headache or deafness, and the mind has been quite clear since the 24th.

CYSTICERCUS IN THE VITREOUS.

DON PEDRO LAGLEYZE describes, in a Buenos Ayres medical journal, a case of cysticercus in the vitreous, this being the only recorded instance of an inter-ocular entozoon occurring in the Argentine Republic. The patient was a man thirty-four years of age. Six months before his eye trouble commenced he had passed a tape-worm. The first symptoms were pains in the supra-orbital arch and flashes of light in the right eye, the power of vision of which rapidly deteriorated. A month after these symptoms commenced he noticed that the vision of the left eye was beginning to be impaired; he then first consulted a medical man, who treated him for more than a year before he was admitted to the hospital at Buenos Ayres, under the care of Dr. Don Cleto Agiurre. There was no injection of either conjunctiva; pupils sluggish, vision much impaired. Left eye: fingers scarcely counted at fifteen centimetres, tension normal, atrophy of papilla. Right eye: an extensive hiatus in the superior half of the field of vision, central vision $\frac{1}{4}$, tension greatly diminished. With the reflector a characteristic cysticercus was seen in the vitreous, with two suckers visible, but not the corona of booklets; it was dead, but apparently had not been long so, for about a month afterwards there was a considerable change, the head having become globular and the neck shrunken. The body, which had been translucent, and therefore appeared red by the transmission of rays from the fundus, was now opaque. The retina was detached at the point where the animal pierced it. The papilla was white, as in the left eye, this being not due to the entozoon, but merely a coincidence. The atrophy continued to increase in spite of remedies.

THE MEDICAL SOCIETY OF LONDON.

THE Medical Society is the first of the London Societies to bring its session to a close. The last ordinary meeting was held on Monday last. Next Monday the annual oration will be delivered at 8.30 P.M. by Professor Humphry of Cambridge, when it is anticipated that a large and distinguished audience will be present. The conversazione takes place immediately after the delivery of the oration.

A HEROIC GIRL.

AT an inquest held at St. Thomas's Hospital on the body of Elizabeth Chandler, aged three years, who died from burns received at the fire which lately occurred in the Borough, the jury returned a verdict of "Accidental death," adding that the conduct of the unfortunate young woman, Alice Ayres, who was instrumental in saving the lives of two other young children, and who herself had fallen a victim to the disaster, was beyond all praise. So far the jury have expressed the opinion of everyone who read the sad story of this brave girl's presence of mind and dreadful death. But we would go a little further, and urge that such conduct is not beyond recognition. Why should not the name of a heroine be kept in memory? and what more appropriate way, in the case of one who saved little children's lives only to lose her own, than by the establishment of a ward for children, or at least a cot, in one of the hospitals, which should bear the name of "Alice Ayres"?

HISTOLOGY OF SYMPATHETIC GANGLIA.

THE paper which was communicated by Dr. Hale White to the Royal Medical and Chirurgical Society, at its last meeting, on the Morbid Histology of the Sympathetic Ganglia, is one which merits some attention. In all researches in which almost negative results are arrived at there is a tendency for the mind to *overlook* and forget. The only change which Dr. White has felt himself justified in pronouncing as pathological is an increase in the number of the elements in the connective tissues of these ganglia—an abnormal condition, that is to say, of the purely supporting structures of the bodies in question. Though this is a conclusion which cannot be cavilled at in the present state of microscopical investigation, yet it must be admitted that it is anything but satisfying to the clinical physician. It may be that more minute methods of examination may at some future time reveal changes of the finest sort in the most intimate structure of the nervous tissues. The possibility of ultra-microscopical alterations of texture still remains to us to explain some affections which are obviously related to disordered action of parts of the nervous system. Chemical or other modes of investigation of the protoplasm of nervous tissues may give us an earlier insight into the molecular disorder which certainly exists, whether it be perceptible or not by any of our present methods of inquiry.

SMALL-POX IN WEST HAM.

Small-pox is widely prevalent in West Ham, and Dr. Drake, the medical officer of health, is stated to have recently reported that no less than 290 fresh cases had come under his notice during three weeks. A house-to-house inspection has been instituted by the guardians with a view of promoting vaccination, and if this work is carried out promptly and systematically, it cannot fail to be of material value in saving the inhabitants from preventable disease and death. Nothing short of the efficiency obtained by the St. Pancras guardians in this matter should be aimed at. But the intervention of the sanitary authority appears to be much needed. Thus, we read in the local press of a girl who suffered from small-pox being found to occupy the same bed as her parents, and this in a small house of four rooms, holding no less than twenty-one persons. Overcrowding is one of the nuisances most dangerous to health, and as such it should be dealt with without delay wherever it is found to exist.

ALVELOZ IN CANCER.

The United States consul at Pernambuco has forwarded to his government a report by Dr. Bandeiro, surgeon to the Hospital Pedro II., on the value of the juice of the alveloz as an external application in cancer. It seems to have been useful in epithelioma of the lips, nose, face, and eyelids, but to have been less successful in ulcerated sarcomas and carcinomas not of the epithelial variety. Several preparations are made with salicylic acid, &c., but it is thought that the juice is far more active when used in a fresh state. The natives employ the cut end of the stem of the plant, Euphorbia heterodoxa, to cauterise the sore, using at the same time a decoction of tobacco leaves. A supply of the prepared juice has been forwarded to the Marine Hospital in Washington and to the Cancer Hospital in Liverpool, from which institutions reports will doubtless be forthcoming if the alveloz juice treatment prove to possess any advantages over other methods of treatment of cancers.

SYPHILIS IN HOOFED ANIMALS.

The Veterinary School of Madrid has reported that the disease from which solipedes are suffering in the district of Villarcayo (Burgos) is syphilis. It is feared that it may extend to animals whose flesh is used for food, and that syphilitic meat may be sold in the markets. A suggestion as to protective legislation, which is stated to have the approval of the Director of Charity and Health and of another important official, has been made to the Royal Council. It is not, however, expected that more will come of it than of numerous other projects which have previously been presented and quietly shelved.

CHOLERA IN EUROPE.

Rumours of cholera from time to time remind us of the prospect of a recurrence of the disease in an epidemic form during the coming summer. The most important announcements have come from Spain, where early in April a considerable number of cases were alleged to have occurred in the province of Valencia. The statement was, however, soon followed by contradictions, and precise information on the subject has since then not been forthcoming. France, however, imposed a three days' quarantine on arrivals from Spain. Since then we have heard that a case has occurred at Osio, not far from Bergamo, and a French newspaper has reported cases at Cairo. In the meantime, the oft-postponed European Conference has again been postponed to May 15th, and it is stated that the India Office will send separate representatives. Switzerland will be represented by M. Bavier, the Swiss Minister to Italy, assisted by Dr. Souderberger and Dr. Reali.

URIC ACID CALCULUS OF ENORMOUS SIZE.

We desire to place on record some particulars of one of the most remarkable calculi that the records of surgery furnish. It was removed by the high operation (Petersen's modification), on Wednesday morning, by Sir Henry Thompson, from a man aged sixty-two. The stone was of an oval form, of pure uric acid, without any phosphatic incrustation whatever. It weighs 14 oz. avoirdupois (405 grammes), and measures 4½ in. long, 3¼ in. wide, and 2⅛ in. thick. The operation was rapid, and performed without difficulty; and the patient's present condition is unusually good and promising.

REMOVAL OF INFECTIOUS CASES.

Mr. W. G. Lacy, of 24, Ringford-road, West-hill, Wandsworth, has introduced an innovation in the means of removal of infectious patients to the several infectious hospitals which is, we think, likely to work well. By employing a private brougham, which he keeps for this purpose, all publicity is avoided, and less excuse is offered to persons to keep infectious cases in their homes on the plea of the injury to their business that the ordinary conspicuous removal entails.

ENTERIC FEVER AT NORWICH.

A somewhat wide and sustained prevalence of enteric fever is in progress in Norwich, and, so far as can be judged at the present time, the disease is more likely to be associated with faulty conditions of sewerage than with the water or milk supplies. Dr. Herbert Airy, of the Local Government Board, is making local inquiry into the matter.

SIR WILLIAM JENNER.

We are happy to be able to state that Sir William Jenner is progressing as favourably as is possible towards recovery.

At the recent meeting of Middlesex magistrates for the transaction of county business, upon the suggestion of the Parliamentary Committee, the Lunacy Acts Amendment Bill was referred to a special committee composed of the justices on the visiting committees of the three county lunatic asylums, with power to confer with the authorities, and to take such steps as might be deemed necessary to secure any necessary alterations. It was also decided to provide an additional asylum for the pauper lunatics of the county to accommodate 1000 patients, the administrative offices and plans generally being so arranged that provision may be hereafter made for additional patients up to 1000.

At the same meeting it was resolved that the committee appointed to superintend the administration of the Adulteration Acts be authorised to seek counsel's opinion as to the power of the county inspectors to require samples of milk in course of delivery, and that the inspectors under the Adulteration Acts be authorised, under the directions of the committee, to pay and charge to the county the reasonable expenses of an assistant and of a witness, and that they be authorised to obtain professional assistance in the conduct of prosecutions in which legal or other difficulties are likely to arise.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of March, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained on the whole less organic matter than in either of the previous months of the present year, the amount being small for this season. The water drawn from the Lea contained slightly more organic matter than the previous month's samples. All the waters were clear and bright.

AT the monthly meeting of the Board of Management of the Manchester Royal Infirmary on the 27th ult., it was stated that there had been a very considerable increase of small-pox in the city during the past month, and in order to meet it the Monsall Hospital Committee had been obliged to erect at once an emergency building to accommodate twenty-four patients. As many as forty cases had been received during the preceding seven days; and there were at the time of the meeting 119 cases in the hospital.

THE question of lay administration of hospitals is not confined to this country. A Madrid paper states that the functions of Director of the Provincial Hospital of that city are now discharged, with assistance, by a lawyer. The Zaragoza *Clinica* also complains that a young lawyer has just been appointed Director of the Hospice of Calatayud.

DR. HUGHES BENNETT will deliver at the Westminster Hospital during the ensuing summer session a short course of lectures on the Recent Advances in Neurology, with their practical application to the investigation of diseases of the nervous system. They will be given on Mondays and Thursdays at four o'clock, beginning on May 4th.

DR. CHAMPNEYS has been appointed Lecturer on Midwifery and Obstetric Physician to St. George's Hospital, in succession to Dr. Barnes. This is an appointment which we feel sure will give general satisfaction.

PROFESSOR LORETA performed his operation of divulsion of the cardiac orifice for the seventh time on April 8th in the surgical clinique of Bologna. The proceeding was successful, and the patient is doing well.

AN exhaustive account of what is known of the therapeutics of antipyrin has recently appeared from the pen of H. Huchard. (Paris: Octave Doin, 8, Place de l'Odéon.)

THE *American Quarterly Journal of Neurology and Psychiatry* has closed its career at the end of its third year of publication.

BROWN INSTITUTION.

THE following is extracted from the Report by the Professor-Superintendent, Mr. Victor Horsley, to the committee of the Brown Institution for the year 1884, and presented to the Senate of the University of London on February 25th.

The report describes the whole of the past year's work of the hospital only, that part of it relating to the work done in the laboratory being an account of researches carried on during the autumn since the appointment of the present Professor-Superintendent on September 1st.

The report of the curative work of the institution has been drawn up by Mr. Ernest Barr, M.R.C.V.S., &c., who has fully maintained the high efficiency of this department.

The most noticeable feature in the list of diseases from which the animals treated have suffered, is the increase in cases of rabies. After a considerable period of complete immunity an outbreak of rabies took place towards the end of the year, which at one time appeared likely to assume alarming proportions. Nearly the whole of the tabulated cases (nineteen) occurred in the course of a few weeks, and many animals in the neighbourhood of the institution were known to have been bitten. Fortunately, however, the outbreak subsided, and for some weeks past no fresh case has come under notice. A suggestion was at one time made by a late Professor-Superintendent (Dr. Burdon Sanderson), but not acceded to by the Government authorities, that the leading symptoms of rabies should be printed on the back of dog-licences. They might, with advantage, be again counselled to follow this good advice.

The success of the stamping-out process as followed in glanders is proved by the continual small percentage of that disease: if it were possible to adopt a plan to pay compensation and destroy those doubtful cases which are so frequently the means of spreading the disease, it would not be too much to hope that in a few years London might be almost free from glanders.

The difficulty noted in previous reports of conducting the in-patient department of the institution has been intensified in a year that has seen the ruin of so many small traders. Day after day it is found that the very poor, those for whose benefit the institution is especially intended, are unable to pay the cost, or anything like the cost, of keeping an animal in the hospital. Frequently, in fact generally, the horse is the chief or sole means of gaining the living of a family, so that when its services are lost, it is as much as the members can do to earn sufficient for daily food, without paying from 1*s*. 3*d*. to 2*s*. 6*d*. daily for the maintenance of the horse.

Another point that might be brought to the notice of the Committee is the absence of a veterinary library. For years past it has been felt as a great inconvenience by gentlemen working in the laboratory subjects relating to animal pathology that there is no collection of foreign or English books of reference. A few pounds spent yearly would go far to lessen the inconvenience.

From September 1st to December 31st, the laboratory has been actively used for various researches in comparative pathology. 1. Dr. Theodore Cash has continued his researches (*a*) into the means of preventing the action of the poison of splenic fever and tuberculosis by means of certain disinfectants; and (*b*) into the subject of visceral innervation and abdominal temperature. 2. Mr. G. F. Dowdeswell, M.A., has been conducting experimental researches into the virus of (*a*) fowl cholera and Davaine's septicæmia, in the course of which investigation he has made the important observation that the organism, "which is presumably the cause," is identical in both diseases; (*b*) hydrophobia; and (*c*) human cholera, especially with relation to the lower animals, and particularly the cause of their power of resistance to the influence of the comma bacillus of Koch. 3. Dr. Wooldridge, who has for some time been engaged in researches on the albumen of the blood, and especially in relation to various forms of anæmia, has been able (by means of the facilities offered him by the institution, in the shape of the gas engine, &c.) to confirm his previous investigations, and to considerably extend them. 4. Dr. Angel Money, by a few experiments, has succeeded in elucidating some of the symptoms which render diagnosis of coarse brain disease uncertain, and he has also commenced a research into the pathological anatomy of paraplegia following interference with the circulation in the spinal cord, a condition of things the correct knowledge of which is of practical importance in the diagnosis of paraplegia in animals. 5. Dr. Erb carried on for six weeks a research into the anatomy of the ear in fishes. 6. I have myself been engaged in a series of experiments on monkeys, which have resulted, I believe, in the demonstration that the loss of function of the thyroid gland is the cause of the obscure disease known as myxœdema. By the same research I have shown that the operation of thyroidectomy, as at present practised by surgeons, is unjustifiable, and should be modified. I have also, as occasion offered (twice), performed inoculation experiments, to lay the foundation of a research into the causation of the melanotic disease to which every white horse beyond middle age appears to be liable. With Mr. Shattock I have commenced an investigation into the healing of wounds by the first intention. This appeared to me desirable on taking office, seeing that it is a subject of vital importance, and one the details of which are as yet unknown.

OUR WAR CORRESPONDENT'S EXPERIENCES IN THE SOUDAN.

No one, I venture to assert, ever knows, or can appreciate to their fullest extent, the true comforts of a happy home until he has been away from it for a time; and surely the feeling is intensified tenfold by what an onlooker, especially a non-combatant, has to face, to see, and to endure amongst the distressing and harrowing scenes observed after a well-contested, hard-fought action on some foreign battle-field. Here, there, and everywhere shocking details present themselves in sufficient abundance to unnerve the very strongest mind, whilst the disparity between order and disorder, betwixt calm and fury, reason and frenzy, is so great as to make the bravest recoil from and shudder at the sickening sights which present themselves again and again on the gory trampled sod.

But hearts may break, and tears may flow;
The bugle will sound, and the soldier must go.

By-the-bye, that reminds me that neither the early morning slumbers nor the noontide siesta of those taking passage in that admirably-arranged troopship *Persian Monarch* were ever disturbed this side of Gibraltar by sounds of martial music. For some reason best known to the officials at home, no enthusiastic bugler—no, not even a scatter-brained drummer—figured amongst the list of troops despatched to the seat of war in the above-named vessel. The situation for the young artillery officer in command was as novel as well as unpleasant a one as could be well imagined. In his dilemma he applied to the captain of the ship, who suggested the use of the ordinary ship's bell, the ringing of which had on the first occasion the effect of instantly bringing all hands on deck to extinguish some imaginary fire—the more hungry in search of their dinner; whilst a general belief that the ship had run into some fog became so prevalent that this substitute for a bugle or a drum had at last to be given up altogether. Of course amongst us there were some carping critics who never let an opportunity slip for saying bitter things against the powers that be—oversight, blundering, &c.; but to me there was something particularly droll, as well as rich, in the practical joke played upon the military element by the transport department at home in depriving Lieut. —— and his subs of two such necessary but at the same time ear-splitting military accompaniments. With fine fast-steaming vessels to order, and with ample funds to freight and despatch them, it has become an easy matter for our Government to transport a large and powerful army even to the littoral of the Red Sea, as a passage of some sixteen days is now quite sufficient to span the distance from Portsmouth to the Soudan. But what a change has already come over the scene! A fortnight since those sturdy fellows in front of me were, with reddened noses, pinched features, and wrapped up in their great military overcoats, trying to dodge the cold nipping gusts of a strong north-easter by crowding together to leeward and under shelter of the ship's warm funnel and casing. Now these self-same men, in the scantiest of attire, and under an increase of thirty degrees in the temperature, are seeking shady corners, or leaning over the gunwale, intent on noting the progress of our ship, and, lost in admiration, are beguiling their leisure hours by watching Sol from his height playing fantastic sport with his rays on the glassy surface of this loveliest of cerulean-coloured seas.

Some smoke, some play at cards, others merry ditties sing,
While idle ones there are who never do a single blessed thing.

Yes, there they are in all directions, from forward to aft, in their shirt-sleeves and trousers, with sunburnt faces, and with heavy drops of perspiration exuding from every pore, crying out about the heat already, and begging for a drop of water—a good long drink to assuage their inordinate thirst; not a few, too, still more overcome by the languor that invariably seizes all on their first visit to the Red Sea, are lying helplessly on their backs beneath a double awning, a barely sufficient protection from the heat and glare of a mid-day tropical sun. Happily, our vessel has made a smart run of it, and by midnight of the 15th the engines are stopped in order to pick up the outer reef buoy on the following morning. An excellent landfall has been made, for just as daylight breaks the desired object is seen about a mile and a half away on our weather bow. Towards it we cautiously proceed at half speed.

WHAT ONE SEES ON ARRIVAL OFF THE PORT.

Breakers on all sides of us. To the right, to the left, they are discerned. Huge white-crested rollers, sending their rainbow-tinted spray aloft, are observed, one after another, dashing over and amongst the coral reefs which encircle as well as protect the harbour of Sawakin, twenty miles away, to which we are bound. Our charts being accurate, and our commander careful as well as very experienced, there is small need of fear in navigating the narrow though straight channel, which, running inside of the reefs and parallel with the shore, leads up to the place we are in quest of. After getting into deeper water our speed is somewhat increased, so that by breakfast-time we come in sight of the shipping, whitewashed houses, and tents of our army, dotted here and there over the sandy-coloured plain. Sawakin (usually spelt Suakin) is situate on the eastern coast of Africa, about two-thirds of the distance down the Red Sea. Its harbour proper, if not land-, is certainly coral-locked; not steep to approach, but from a very deep middle channel the water suddenly shoals to either shore. Its entrance is very narrow, and the mouth of it is guarded by a British gunboat lying there for that purpose. As most of the vacant berths are occupied by transport and other ships, all vessels arriving off the main harbour must heave to (they cannot anchor in sixty fathoms), and wait until boarded and brought in by a Royal Naval navigating lieutenant appointed specially for that purpose. Proceeding cautiously up harbour, the hospital ship *Ganges*, suitably painted white, is first noticed as she lies moored along the northern shore. Astern of her is the B.I. steamship *Bulimba*; she provides the expedition with machine-made ice, and is devoted to the reception of medical and surgical cases of a specific nature; whilst abreast of her, on the opposite side of the fairway, is anchored (or supposed to be so, for she sometimes drags her anchor and falls foul of her consorts) the hulk for the reception of small-pox patients. Still further westward and nearer to the town lies the *Arab*, of the Union line, a naval transport ship used as a sort of headquarters by that courteous and very indefatigable officer, Captain Fellows, R.N., and the really hard-worked staff immediately under his command. Astern of the *Arab* is the *Calabria*, utilised as a distilling vessel, whence issue the many thousands of gallons of bright clear water supplied daily for the entire force in camp. After inspecting her,

WE GO ON SHORE

at Quarantine Island, and close to the water's edge see lines of white tents of every shape and pattern. The best are the square-shaped ones. They are made of a material something like twill, lined with yellow calico, double roofed, both lofty and airy, and have four openings, one on each face, for the freer admission of both light and air. The few bell-shaped ones there are have to be exchanged shortly as soon as the new can be obtained from the store. To the eastward are pitched those belonging to the firm of Messrs. Lucas and Aird, railway contractors for the Berber line; these are in turn succeeded by the auxiliary hospital pavilion, and farther on follow the private tents of Surgeon-Major Hinde and the medical staff attached to that institution. The rising ground upon which these temporary habitations are placed is light-yellow in colour, and of a sandy porous nature. This sand is only some eighteen inches deep, a very hard, white, compact, coral formation existing beneath. No moisture, therefore, ever remains long on the surface. The latrines, placed to leeward and in rear of the tents, are simply spaces enclosed by bamboos and coarse Indian matting, supplied with a strong horizontal wooden bar, beneath which are two or three zinc buckets, which, with sand ready at hand, are used and cleaned upon the earth-closet system. Offensive smells seldom result from their use, and if they should at any time become obnoxious, the effluvium could readily be removed by the free use of disinfectants—MacDougall's powder, &c. Passing by the engineer's camp, crossing the causeway, and entering on the desert, on a somewhat elevated sand mound is seen

THE MAIN OR BASE HOSPITAL,

under the immediate superintendence of Brigade Surgeon Tanner. This camp hospital consists of a number of tents, most of which are of Anglo-Indian pattern and construction. They are not, as elsewhere, placed too near to one another, but are pitched with some regard as to method and regularity. In the centre of the group is a large square pavilion, called the operating theatre, and on entering it one is at once struck with the comfort and perfection of arrangement the interior of this place displays. An operating-table occupies the central position, and on the walls or sides of this calico habitation are hung up square creamy-white coloured bags, containing sponges, lint, bandages, antiseptic dressings, in fact any and everything needed, and that should be readily accessible in case of urgency or hurry. Already another correspondent, as well as myself in a former communication, has paid a well-merited compliment to Surgeon-Major Tobin for his energy and painstaking in this special portion of the department. Now, the store-room, or rather store-tent, with its heterogeneous assortment of goods, medicines, hospital equipment stores, and sanitary necessaries, must not be omitted from the list. I do not know the name of the officer in charge of it; but for the method, as well as the care displayed in the arrangement of the various odds and ends, from a bedstead down to a mosquito curtain, the superintendent deserves my warmest congratulations for the manner in which his different duties have been carried out. Each of the officers' hospital-tents can accommodate about eighty beds; the bedstead itself is very light and formed of thin split bamboos, and each one is supplied with more than sufficient bedding for use in this hot climate. Before leaving the subject of the base hospital I may take this opportunity of thanking the medical officers there for their courtesy to me on every occasion, and more especially give my thanks to Surgeon-Major Allan for supplying me with statistical information, which he, as the able representative of the Registrar's Department, is always desirous as well as capable of giving. Adjacent to, but south-west of, the "H" Redoubt, is

THE NEWLY-SELECTED CEMETERY.

Up to the time of my quitting Sawakin, the former burial-ground was close to and situate just opposite and to windward of where the transport ships *Arab*, *Bulimba*, and *Ganges* are moored. In this badly-selected portion of ground set apart for burial purposes, after our recent actions with the foe, a great number of interments had taken place, and as the graves for the corpses could not be dug more than some eighteen or twenty inches deep in consequence of the existence of a very hard substratum of coral, whenever the wind blew from the northward (the usual direction during the night and after-portion of the day), a horrible effluvium percolated through the superficial layer of sand, and was wafted directly across the vessels moored close to it. This I am told not only proved most offensive to the nostrils of all on board, but threatened most dangerous results from a sanitary point of view. During my sickness on board the *Arab* a very strong remonstrance against any further interments was made to the officials at head-quarters, and resulted in their ordering an immediate discontinuance of any more burials in this spot, and in the selection of a more appropriate *locale*—the new cemetery above referred to. Let us now pay a flying visit to

THE ORDNANCE WHARF,

situated at the head of the creek, and just above where our men-of-war are anchored. The major in charge of this place (where all the military stores are accumulated) evidently has his hands full enough to discharge with efficiency the duties of so trying as well as difficult a department. Around the officers' tents, alongside of, and adjacent to the pier, lie scores of bales, hundreds of boxes, and packages of every conceivable shape, size, and description. In one spot carts are drawn up in a row; in another groups of harness. Not far from these, again, coils of telegraph wire and a host of water-pipes are seen; and would it be believed that by some wiseacre arrangement at home, amongst all this heterogeneous assortment of general merchandise and collection of commercial goods, a medical officer has himself to go, search for, and pick out the requisites for his own department. Dr. ——, of the Base Auxiliary Hospital, *assured me—in fact, I saw it with my own eyes*—that it had taken him some days to segregate from the rest the few hospital belongings urgently wanted, and that were then lying on the ground in front of me. A medical officer might be spared this difficulty surely, especially when in face of the enemy, by all the medical stores and hospital equipments being forwarded together in a hospital vessel, or placed in some portion of a ship where they could be readily got at on her arrival in port. The *Ganges* and her arrangements throughout set our authorities an admirable lesson in medical transport, and her well-organised system could certainly be copied with advantage by anyone desirous of improving the conditions under which these things are now done. Yet another little matter requires looking into. I have every reason for believing that in the present campaign one or two senior medical officers have taken a passage in one ship, while their junior brethren are sent out possibly some days afterwards in another. The one party arrives without his assistants, without medicines or appliances, to find nothing ready, everything to do, everything to organise, and no junior officer to lend assistance in the difficulty. More than this: when the "subs." present themselves, Brigade and simple Surgeon So-and-so are unknown to one another. How, then, in the name of goodness, can the principal medical officer direct with advantage? He should be acquainted with the capacity, as well as the fitness, of any and each officer for any special post he may feel desirous of appointing him to, and not have all this organisation to go through when the services of all his men are urgently needed in the field. That the principal medical officer has perfected his arrangements in the Soudan with great judgment and considerable tact and skill is no answer in face of a possible difficulty likely to occur in less able hands; and it would be well if the Home officials, acting on the well-known maxim that "prevention is better than cure," considered the propriety of holding a course of practical field hospital training during the summer season, and when perfected in drill send the officers and their bearer companies all out together, and not despatch them piecemeal abroad to serve under new officers and in new duties, as they hitherto seem to have been doing. And now let me say a word or two about

THE CLIMATE,

concerning which so much has already been written and said. Climate, everyone knows, is an important factor in the success or otherwise of any expeditionary undertaking. Especially would it be so in the African Soudan. It is a well-recognised fact amongst travellers and persons who have lived out in the Soudan that, with the exception of the Persian Gulf, there is no hotter or more unhealthy locality than the western littoral of the Red Sea in the summer season. During the months of October, November, and December, even up till the beginning of April, the climate is pleasant and healthy enough, with genial warm days and cool nights, a cloudless sky, dryness of air, an average daily temperature of 78° F., and refreshing sea-breezes setting in about 10 A.M. and continuing till after dusk, the climate of the Soudan at this season is by no means prejudicial to health, and not one-half as bad as is commonly supposed. The sense of freedom, moreover, and elastic buoyant health, which so many describe as experiencing when they first arrive out, and the stimulus to appetite afforded by a brisk early march across the sandy plains, are the best evidences of salubrity, as well as of a certain amount of health-promoting power. The existence of so small a percentage of sick amongst the number employed during the past three months is more than confirmatory of this view; but let April pass and a complete change sets in. The thermometer no longer remains at 70° or 80° during the day, and falls as low as 50° at night; but rises to 112° in the shade, and remains at 100° during the night. No fresh sea-breeze sets in to cool this awful temperature, and man as well as beast fall prostrate beneath its influence. The super-heated air becomes then terribly relaxing, and has a most depressing effect upon the animal economy. Such a feeling of languor and lassitude seizes on one that it cannot by any effort of will be shaken off. The depression increases hourly, and, possibly with scarce any further appreciable warning, heat apoplexy strikes its victim and speedily relieves him from any additional tortures of mind and body; or to take a more lingering case still, after such a terrible drain upon the system, such an exhaustion of all the vital powers, through loss of appetite and deprivation of sleep, dysentery, that scourge of the tropics, sets in, with all its chain of most distressing and painful symptoms, and continues with all its agonising characteristics until death at last comes along to finish what heat and the overpowering influences of such a detestable climate has begun. Granted, some have withstood the climate well enough; but the majority have but too easily succumbed to its disastrous effects. I believe 40 per cent. were invalided last summer season, and nothing short of sheer madness should tempt any government to sanction the retention of troops, especially under canvas, in so dangerous a summer climate as that of the African Soudan. My own experience in the Red Sea (by no means limited) would scarcely warrant my giving so dogmatic an opinion on this subject were not my ideas backed up by what I hear from all others who have lived out there. They are unanimous in condemnation of leaving the troops at Sawakin to stew in their own gravy. The Arab knows what the effect of permitting this will end in. From what I learnt from a friendly sheikh, Osman Digna, after his last great attempt on March 22nd, is reported to have said, "I shall no longer attack the enemy in force; I shall retire to the mountains, and simply harass his lines of communication; the climate during the coming season will do the rest." God forbid, say I, it ever should. And the question naturally arises,

WHAT SHOULD BE DONE WITH OUR TROOPS?

Perhaps the Government are in a strait, having found out to their cost that it is a far easier matter to get into a difficulty than it is to escape out of one. To remove our troops from the Soudan at this juncture simply means death to, and total annihilation of, those friendly natives we leave behind us at Sawakin; and yet a decision to leave our men out there, under the scanty protection afforded by a tent's cover, will be fraught with equally unsatisfactory results. The consensus of opinion amongst my press colleagues is decidedly adverse to such a determination on the part of the Horse Guards. More than this, one or two correspondents have already spoken out with no uncertain sound. They have issued a warning not one moment too soon, as well as stated their opinions in language not one word too strong. Our only policy now is to confess to a serious mistake, and get out of the dilemma as soon as we possibly can. Now,

THE PAGES OF JOURNALISM

are always open for the insertion of fair criticism, in order not only to expose arrant blunders and point out grave and wretched mistakes, but also to accord honour where honour is due. Now, while paragraph upon paragraph in the public press has been lavish in its praises of the conduct and bravery of our English troops, especially the Berkshire regiment, the sailors, and marines, and have not hesitated—and very justly so, too—to speak of the thorough efficiency with which the Transport Department has been administered in the Soudan by such able officers as Captain Fellows, R.N., and the other members of his staff, surely we must not, indeed we cannot, forget that there are other brave hearts (the Medical Staff) who have equally borne their share of the heat and burden of the day. Amongst that heroic band there has, too, been no shrinking, no holding back, but always hard at work—ay, in the very thick of the fight, too, these men have carried their lives in their hands, and by their praiseworthy conduct and painstaking certainly deserve a modicum of that approval and praise a satisfied and generous public is more than ever ready to bestow. John Bull has a long urse we know, but in spending his money freely he certainly desires to see something for his outlay, and he may rest assured (lay correspondents have noticed it) that the sick and wounded are well cared for, and that no department has been better administered in the Soudan than this has been. The hospital accommodation has as yet been ample. The bearer companies are complete and efficient, the medicines and the comforts sufficient and good, whilst the officers themselves have been kind, patient, as well as brave unto death. Poor Lane was nearly the first to fall, and Surgeon-General O. Barnett may be well complimented indeed for the excellence as well as the efficiency of his arrangements throughout the present campaign.

UNIVERSITY DEGREES FOR LONDON MEDICAL STUDENTS.

A NUMEROUS and influential deputation of the Metropolitan Counties Branch of the British Medical Association was received by the Senate of the University of London (Sir James Paget in the chair) on Wednesday last, at 5 P.M. From the large attendance of the members of the Senate of the University there is every reason to think that the objects of the deputation are engaging, at least, the serious attention of those interested in the cause of medical education.

Sir JAMES PAGET, in opening the proceedings, informed the deputation that the report of the Council of the Metropolitan Counties Branch of the British Medical Association had been in the hands of each member of the Senate, and had received the earnest consideration of that body. He would be glad to hear any remarks from the members of the deputation.

Mr. MACNAMARA, President of the Branch, said that the chief object of the deputation was to obtain from the Senate of the University some promise that the examinations of the University for the degree of Doctor of Medicine should undergo certain modifications which would have the effect of rendering it possible for the majority of London medical students to obtain a degree in Medicine. He did not wish to define accurately the changes which ought in the opinion of the deputation to be made, but it would be sufficient if the Senate would undertake to make such concessions as would meet the necessities of the case. Speaking for himself, Mr. Macnamara considered that the present examinations were too stringent only in the requirements of the Preliminary Scientific and Matriculation Examinations; but he did not think there would be any occasion to lower the standard of the final examinations. He urged that the time at the disposal of medical students generally being limited, it should not be wasted by the acquisition of knowledge which would ultimately prove useless.

Dr. BRISTOWE urged that the preliminary examinations were unnecessarily severe, and considered that all that was necessary for the medical student to become a sound practitioner, and deserving of a degree, was that he should have a tolerable general education, and that he should be well grounded in the practice and theory of medicine.

Dr. CHOLMELEY was of opinion that the examinations were too stringent all round, and hoped that the Senate would see its way to compliance with the objects of the deputation.

Dr. LAUDER BRUNTON said that there was a want of sympathy between the University of London and the medical schools, and this was different from what existed at other Universities, such as Victoria and Edinburgh. In the last named Universities the teachers of the students formed part of the examining body of the University. At the University of London, the teacher seldom being the examiner, it was possible for the candidate to fail to satisfy the examiner, because what the teacher perhaps considered unimportant the examiner might regard as very important and give discredit accordingly, and *vice versâ*. He suggested that a less severe curriculum should carry with it the title of M.D., whilst the present stringent course should confer the degree of Doctor of Medical Science.

Dr. WADE (Birmingham) hoped that the Senate would bring the degree in Medicine within reach of the majority of medical students.

Sir WILLIAM MAC CORMAC pleaded for modifications in the earlier examinations only.

Sir JAMES PAGET said it was a mistake to suppose that it was useless to approach the Senate with the views which the deputation had put forward. It was the object of the Senate of the University of London to raise medical education in all its branches, and at the same time to make the degrees accessible to medical students. But it was very difficult to strike a fair medium between all the various views which had been laid before the Senate. The Senate had considered how this might best be done in conformity with the aim of the University that its M.D. degree should represent a higher degree of attainment than that expressed by the M.D. degree of any other University. He assured the deputation that the Senate was very far from disregarding the views of others, and he asserted that movements had gone on in the Senate which already had resulted in considerable modification—as, for example, in the Preliminary Scientific Examination. The deputation might rest assured that their views would receive careful attention.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Blackpool Urban District.—The death-rate for Blackpool during 1884 was 19 per 1000, including visitors; but on making the needed corrections the rate was 17·1, which exhibits an excess on that for 1883, the excess being accounted for by the prevalence of autumnal diarrhœa. For much the same reason the infant mortality under one year reached 146 per 1000 births registered, as opposed to 139 in the previous year. These higher death-rates have to a large extent been due to mortality in the summer quarter, and, as Dr. Welch remarks, they are suggestive, in connexion with the overcrowding of the town at that season, of want of cleanliness personal and domestic, and of the general neglect of children. Superadded to these normal conditions, the heat of 1884 was exceptional. But Blackpool, though a principal health resort, is not altogether free from conditions which are distinctly inimical to health. Some of the old large privy-pits, which give off foul vapours and contaminate the subsoil, still exist; many of the ash-pits are uncovered, and are almost as great a nuisance as the privy pits; drainage is defective in nearly all the older houses, and the ventilation of the sewers is by no means perfect. Fortunately, however, sanitary work, which aims at the removal of these causes of disease, is steadily in progress. Thus, no less than 630 ash-tubs replaced offensive ash-pits last year, a house-to-house inspection is securing many improvements as to internal drainage, and Dr. Welch's advice as to conveying the sewer air above the level of the houses and otherwise improving the system of sewerage is being considered. The Sanatorium, which we assume is the same faulty one as formerly, did some substantial good by securing the isolation of twenty infectious cases. Some work of disinfection is also carried out, but it would appear to be hindered from want of proper appliances. Blackpool is so largely frequented by those who are in quest of health, and it is so deservedly a popular pleasure resort, that we hope no efforts will be spared in the direction of getting rid of all removable causes of disease, and in providing the town with suitable modern buildings and appliances for preventing the spread of infection amongst the population.

Aylesbury Rural District.—Dr. Hilliard reports that during the drought of 1884 the sources of the Chiltern Hills water-supply failed to give an adequate service. This is a most unfortunate occurrence, since one of the principal sanitary wants of many places within reach of the company's works, lies in the substitution of the Chiltern Hills supply for the suspicious well waters. Both scarlatina and diphtheria were somewhat severely prevalent in the district, the latter notably at Bierton. Dr. Hilliard refers to the analogy between the two diseases, but expresses the belief that they are distinct in their origin and that neither is capable of producing the other. On the other hand, he suggests that the conditions which favour the germination of the scarlatina spore are equally favourable to the development and support of the seeds of diphtheria, so that the two diseases flourish contemporaneously, and in the theory that both may have evolved from a remote common ancestor he sees a harmony with the new favourite evolution theory. The mortality of the district was 18 per 1000 for 1882, in 1883 it was 17, and for 1884 it had fallen to 16.

Sittingbourne Urban District.—The general sanitary work of this district is reported by Dr. Sutton as progressing favourably, and the death-rate for last year is given as 16·6 per 1000. The infectious hospital has again proved to be a great safeguard against the spread of disease. Four patients were attacked with scarlatina, they were removed to the sanatorium, and no other cases ensued. The slaughter-houses and bakeries have been carefully inspected, and such defects as were found in them and elsewhere have been remedied.

Milton Rural District.—Here Dr. Sutton reports a death-rate of only 11·9 per 1000. The prejudice formerly existing against isolation in the Sittingbourne and Milton Joint Hospital is disappearing, and sanitary work is steadily advancing, defective conditions being remedied by such structural alterations as are needed.

Watford Urban District.—In his annual report for 1884 Dr. Brett draws the serious attention of the Local Board of Health to the want of means of isolation for non-pauper patients, the only accommodation available being an iron shed on the workhouse grounds, and even this is not furnished. He also advocates the provision of efficient sewer ventilation, and points out that the iron shafts at present existing are useless for this purpose. Permanent means of sewer flushing are also wanted to replace the work now inefficiently carried out by water-carts. Excluding deaths, occurring in the workhouse, of persons from outlying places, the rate of mortality was 17·8 per 1000.

Hastings Urban District.—The borough of Hastings, with a population now estimated at 46,310, had in 1884 a death-rate of 15·9 per 1000, which is below the average of that which prevailed during the preceding ten years. The zymotic rate was 1·8 per 1000, and it included 28 fatal attacks from diarrhœa, which was more than usually prevalent amongst children. For some of the zymotic diseases the sanatorium was most useful, 45 patients, including 31 cases of scarlatina, being admitted during the year. A thorough system of house inspection is in progress, 790 premises having been overhauled during the past year, and many defects being in consequence remedied. Dr. Knox Shaw also reports an improvement in the removal of house refuse from premises. A Bill is to be presented to Parliament which includes certain clauses as to sanitary matters. One relates to the appointment of a building surveyor, an officer who is really essential in every populous place where the authority are desirous of seeing efficient building bye-laws properly carried out. Another requires notification of infectious diseases from both the occupier and any medical practitioner in attendance. Opposition to that part of this provision which relates to the medical practitioner is being raised by many medical men in the borough. A third clause authorises the construction of a destructor for the treatment of all forms of waste refuse.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5799 births and 3994 deaths were registered during the week ending April 25th. The annual death-rate in these towns, which had been equal to 25·0 and 23·2 per 1000 in the two preceding weeks, rose again last week to 23·4. During the first three weeks of the current quarter the death-rate in these towns averaged 23·9 per 1000, against 24·1 in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 15·7 in Derby, 17·4 in Portsmouth, 18·4 in Leicester, and 18·8 in Birmingham. The rates in the other towns ranged upwards to 31·2 in Sunderland, 32·2 in Preston, 31·9 in Cardiff, and 35·4 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the eight previous weeks from 377 to 484, further rose last week to 524; they included 213 from measles, 127 from whooping-cough, 45 from diarrhœa, 42 from small-pox, 40 from "fever" (principally enteric), 32 from scarlet fever, and 25 from diphtheria. No death from any of these diseases was registered last week either in Derby or in Bolton; whereas they caused the highest death-rates in Manchester, Cardiff, Sunderland, and Newcastle-upon-Tyne. The greatest mortality from measles occurred last week in Manchester, Sunderland, and Newcastle-upon-Tyne; from whooping-cough in Cardiff and Blackburn; from scarlet fever in Leicester and Sunderland; and from "fever" in Portsmouth, Salford, and Norwich. The 25 deaths from diphtheria in the twenty-eight towns included 10 in London, 7 in Liverpool, 2 in Preston, and 2 in Newcastle-upon-Tyne. Small-pox caused 72 deaths in London and its outer ring of suburban districts, 1 in Bristol, 1 in Liverpool, and 1 in Manchester. The number of small-pox patients in the metropolitan asylum hospitals, which had increased in the preceding four weeks from 830 to 1062, declined again to 1034 on Saturday last; the admissions, which had been 141, 185, and 307 in the previous three weeks, declined again last week to 246. The Highgate Small-pox Hospital contained 89 patients on Saturday last, 26 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 512 and 449 in the preceding two weeks further declined last week to 382, and were 41 below the corrected weekly average. The causes of 82, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Bristol, Leicester, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, Derby, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 25·0, 23·4, and 23·3 per 1000 in the preceding three weeks, further declined to 22·7 in the week ending the 25th ult., and was 0·7 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 12·9 in Leith and 18·3 in Greenock, to 23·7 in Paisley and 27·1 in Glasgow. The 555 deaths in the eight towns included 30 which were referred to whooping-cough, 20 to measles, 14 to diarrhœa, 9 to "fever" (typhus, enteric, or simple), 4 to scarlet fever, 4 to diphtheria, and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 68 and 76 in the preceding two weeks. These 81 deaths were equal to an annual rate of 3·3 per 1000, which was 0·2 above the mean rate from the same diseases in the twenty-eight English towns. The deaths from whooping-cough in the eight towns, which had been 34, 17, and 23 in the preceding three weeks, further rose again to 30 last week, of which 19 occurred in Glasgow, 4 in Edinburgh, and 3 in Greenock. The 20 fatal cases of measles showed a decline from recent weekly numbers, and included 19 in Glasgow. The 14 deaths attributed to diarrhœa differed very slightly from the average. The deaths referred to "fever," which had been 10 and 7 in in the previous two weeks, were 9 last week, of which 3 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. Three of the four deaths from diphtheria were returned in Glasgow; and the 4 from scarlet fever included 2 in Glasgow and 2 in Paisley. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 134 and 131 in the preceding two weeks, further declined to 118 last week, but were 9 above the number returned in the corresponding week of last year. The causes of 72, or 13 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 32·2 and 33·7 per 1000 in the preceding two weeks, further rose to 34·0 in the week ending April 25th. During the first three weeks of the current quarter the death-rate in the city averaged 33·3 per 1000, the rate during the same period not exceeding 22·6 in London and 18·6 in Edinburgh. The 230 deaths in Dublin last week showed a further increase of 2 upon the numbers in the two preceding weeks, and included 28 which were referred to the principal zymotic diseases, against 29 in each of the two preceding weeks; 15 resulted from measles, 4 from "fever" (typhus, enteric, or simple), 3 from scarlet fever, 3 from diarrhœa, 2 from whooping-cough, 1 from diphtheria, and not one from small-pox. These 28 deaths were equal to an annual rate of 4·1 per 1000, the rate from the same diseases being 3·3 in London and 2·1 in Edinburgh. The fatal cases of measles in Dublin, which had been 19 and 15 in the previous two weeks, were again 15 last week The deaths referred to "fever" showed a decline of 4 from the number in the previous week; while the deaths from the other zymotic diseases scarcely differed from the numbers in recent weeks. Six inquest cases and 6 deaths from violence were registered. Nearly a third of the deaths were recorded in public institutions. The deaths of infants showed an increase upon those in the previous week, while those of elderly persons had declined. The causes of 32, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL ARRANGEMENTS IN CASE OF WAR.

In case of war, the Director-General of the Army Medical Staff is believed to have arranged for the employment on active service of a large number of civilian surgeons at such a rate of pay as to secure the services of really good men—£3 a day is mentioned. It would be cheaper to do this than to give an indefinite number of commissions in the Medical Staff, as in that case, at the conclusion of operations, the number of medical officers would far exceed the requirements of the service. As almost all the officers of the staff would be ordered abroad, the home duties would be performed by retired medical officers and civilian surgeons engaged for the emergency, with perhaps one medical officer on full pay in charge of each important hospital or station.

Surgeon-General Charles Dodgson Madden, of the Army Medical Staff, who served with distinction in the Crimean, Indian mutiny, and Abyssinian campaigns, has taken over the position of Principal Medical Officer to the troops in India, vice Surgeon-General Sir A. D. Home, V.C.

It having been decided to strengthen the medical department at Quetta, in view of the augmentation of troops there, Surgeon-Majors Montgomerie, Blennerhasset, and Fitzroy Maclean, of the Army Medical Staff, have been ordered thither, and several other officers of the same department have also been placed under orders for the same destination.

War Office.—Army Medical Staff: Surgeon-Major Tobias Barnwell is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Edward Eustace is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major William O'Byrne White is granted retired pay, with the honorary rank of Brigade Surgeon; Deputy Surgeon-General Edward Malcolm Sinclair, M.D., has been placed on temporary half-pay on account of ill-health; Surgeon-Major William Frederick Ruttledge is granted retired pay, with the honorary rank of Brigade-Surgeon.

India Office.—The Queen has approved of the retirement from the Service of the undermentioned Officers of Her Majesty's India Military Forces:—Deputy Surgeon-General Arthur James Payne, M.D., of the Bengal Army; Deputy Surgeon-General William Pearl, of the Madras Army; Brigade Surgeon Edmund Eyre Lloyd, of the Madras Army; Surgeon-Major Thomas Stick Veale, of the Bengal Army. The undermentioned Officers have been granted a step of honorary rank on retirement:—Deputy Surgeon-General Arthur James Payne, M.D., of the Bengal Army, to be Surgeon-General; Brigade Surgeon William Peyton Partridge, of the Bombay Army, to be Deputy Surgeon-General; Surgeon-Major Robert Pringle, M.D., of the Bengal Army, and Surgeon-Major Thomas Stick Veale, of the Bengal Army, to be Brigade Surgeons.

Militia Medical Staff.—Surgeon Thomas Allman, 3rd Battalion, the Connaught Rangers, to be Surgeon-Major.

Admiralty.—The following appointments have been made:—Surgeon H. S. R. Sparrow, to the *Asia;* Mr. R. F. B. Halpen, to be Surgeon and Agent at Arklow, Mizen Head, and Kilmichael; and Mr. John Macdonald, to be Surgeon and Agent at Ardrossan.

Artillery Volunteers.—2nd Devonshire: Alfred Hughes Twining, Gent., to be Acting Surgeon. 1st East Riding of Yorkshire: Acting Surgeon William Draper to be Surgeon.

Rifle Volunteers.—4th Hampshire: Surgeon Henry Geary Dyer, from the 2nd Hampshire Rifle Volunteer Corps, to be Surgeon; Acting Surgeon Edward Roe, from the 2nd Hampshire Rifle Volunteer Corps, to be Acting Surgeon; Acting Surgeon Justyn G. D. Douglas, M.D., from the 2nd

Hampshire Rifle Volunteer Corps. to be Acting Surgeon. The above-named officers will be considered to have received Commissions of the same rank and date as those previously held by them in the 2nd Hampshire Rifle Volunteer Corps.—2nd Volunteer Battalion, the Worcestershire Regiment: Honorary Assistant-Surgeon William Smith Batten to be Surgeon. 1st Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Surgeon and Honorary Surgeon-Major Robert Fothergill resigns his Commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.

"Audi alteram partem."

DR. WEBER'S CROONIAN LECTURES.

To the Editor of THE LANCET.

SIR,—In one of Dr. Hermann Weber's interesting Croonian Lectures on the Hygienic and Climatic Treatment of Chronic Pulmonary Phthisis, which have just appeared in THE LANCET, he expresses a hope that some means may eventually be discovered of destroying the bacillus and its spores, either in the air we breathe or in our tissues, without injury to ourselves. I have long thought that if we are to contend successfully with phthisis, and set some limit to its diffusion, it is in the direction here indicated that our labours may most profitably be expended. For, as Dr. Weber remarks, "when once the system is infected, we do not yet know of any parasite-killing remedies which, in effective doses, would not injure the host together with the parasite." The mischief, in fact, is then done, the fatal seed is sown, the bacilli are protected within the tissues and secretions of the lungs, and antiseptics are comparatively useless. *On the subject* of disinfectants in their varied bearings much has been written of late years: some apparently coagulate albumen; others oxidise organic matter; while others, again, are fatal to the growth and increase of microzymes. Many of these substances have long been used in cases of sickness, and in numerous instances beneficial *results have* followed their adoption. But though we are often told that antiseptic gases sufficiently potent to destroy contagium cannot be tolerated by the living tissues, we still know comparatively little regarding the amount of rough usage the respiratory organs are capable of enduring, not only with impunity, but in some cases with apparent advantage. The information we possess on this subject is certainly scanty; still, certain facts have been recorded which tend to show that healthy lung tissues may be beneficially influenced by the action of disinfectants, and at times *seemingly* protected from the inroads of the bacillus. Whether in such cases these organs become so altered in their chemical composition, or in their *vital* properties, as no longer to prove a congenial soil for the growth of the parasites, or whether the bacilli and their spores are themselves destroyed, we have at present no means of deciding. In confirmation of these remarks, I would refer to what really may be looked upon as extended experiments on antiseptic remedies, continually and efficiently carried out in the north-western Highlands and islands of Scotland. The great majority of the inhabitants of these districts unwittingly expose their lungs to an atmosphere largely charged with disinfecting fumes, thereby teaching us a useful lesson on the extraordinary tolerance of the respiratory organs to such sources of irritation. I will briefly describe the mode of life of these Highlanders in so far as the construction and heating of their dwellings is concerned, as in this manner the singularly abnormal atmospheric conditions to which they are exposed may be most conveniently studied. The houses to which I refer are known in the Highlands as "bothies," and are the homes of the hardy Crofters to whose grievances public attention has of late been so strongly directed. Many of them live under the same roof as their cattle, and in numerous instances the air of the dwelling reeks with the [illegible] ammoniacal exhalations given off from the excretions of these joint inmates of the cabin. These primitive dwellings are warmed by a peat fire kept constantly burning in the centre of the floor; the luxury of a chimney is often altogether unknown. The smoke which rises from the combustion of this fuel, after thoroughly diffusing itself through every nook and corner of the building, makes its escape by a hole in a corner of the roof. Now, it may be asked, how is the health of these persons influenced by inhaling constantly both by day and by night such an atmosphere as this—an atmosphere so pungent that considerable irritation of the eyes and nostrils is frequently experienced by those exposed to the fumes? Generally speaking, these Highlanders are remarkably vigorous and long-lived, and singularly exempt from the ravages of tubercular phthisis. Indeed, so rare is consumption in these hovels that I was led to investigate the causes of this immunity upwards of twenty-five years ago, and published the results of my inquiries in an article on "The Non-prevalence of Consumption in the Hebrides and along the North-Western Coast of Scotland," which appeared in the *British and Foreign Medico-Chirurgical Review* for October, 1860. At that time I visited most of the districts to which my investigations extended, and from what I saw and heard came to the conclusion that the comparative immunity from phthisis which these persons enjoy is to be ascribed, chiefly at all events, to the inhalation of the peat smoke and the antiseptic ingredients contained therein, the tar, the creasote, and the tannin, together with various volatile oils and resins. Black unctuous peat is rich in these substances. At that time, I need hardly say, nothing was known of the bacillus of Koch. It further appeared that any exemption from attacks of consumption which these Highlanders enjoy was only extended to them so long as they resided in their smoky huts. When they migrated to other parts of the country, or took up their abode in chimneyed dwellings, they often suffered like their neighbours; nor after the lungs once became infected was a return to the homes of their fathers followed by favourable results; the fumes of the smoky cabin then exercised no curative influence. The inference to be drawn from these remarks is sufficiently obvious: when the bacillus has once established itself in the lungs the time for antiseptic remedies has gone by. On the other hand, where there is merely a predisposition to phthisis, whether hereditary or acquired, where also the climatic or social conditions for its diffusion are favourable, and where healthy persons are brought into close contact with those who are suffering from the disease, there it is reasonable to assume that disinfectants may prove of great value as prophylactics. Hence we may anticipate that in the course of time an efficient system of aerial fumigation will not alone assist the physician in warding off disease, but may enable the surgeon also to dispense with the cumbrous appliances associated with antiseptic dressings and the steam-diffusing urn. I am, Sir, yours truly,

Manchester, April, 1885. JOHN ED. MORGAN, M.D. Oxon.

THE VICTORIA UNIVERSITY, MANCHESTER.

To the Editor of THE LANCET.

SIR,—In reference to the paragraph in your issue of April 25th relating to the facilities for graduation offered by this University to qualified practitioners, I wish to be allowed to state that attendance upon lectures in a college of the University for at least two years is indispensable in all cases before graduation. This is a provision of the Charter empowering the University to grant medical degrees, and is one which the authorities have no power to dispense with. I should be much obliged if you would publish this explanation, as I have received many letters written under an impression that the degree of M.B. is now offered to qualified practitioners on condition only of their passing the Intermediate and Final Examinations for that degree. The new regulation simply excuses those whose qualification is anterior to 1885 the Preliminary Examination in Science and the attendance thereat.—Yours faithfully,

April 28th, 1885. ALFRED T. BENTLEY, Registrar.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—It would appear that the Council of the College, in their proposed new Charter, desires to perpetuate a grievance, and to still render meetings of Fellows and Members inoperative, by providing that only business shall be entertained which has *the consent of the Council*. What would be thought if the Government—with the view, for instance, of silencing the Home Rulers—were to enact that nothing should be brought forward in the House of Commons without the consent of the Cabinet? And yet this is the position in which the Council of the College desires to keep the Fellows and Members when proposing to meet in their corporate capacity. I feel that such legislation, or the desire to retain it, by those appointed to represent without fear or favour a great English institution, is much to be regretted. If the right of meeting is to be conceded at all, let it be free and unfettered, or it is not worth having at any price. I trust that a representation will be made to the Home Secretary upon this point, before an unconstitutional regulation is allowed to form part of the revised Charter of our College. I am, Sir, your obedient servant,

Liverpool, April 25th, 1885. REGINALD HARRISON.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

PUERPERAL FEVER AND PRACTITIONERS.

AT an inquest held here last week upon the body of a female who died a few days after her confinement, the cause of death was shown to have been puerperal fever. It appeared that the gentleman who attended at the confinement was unable to attend, on an urgent message being sent as to the patient's condition, but another practitioner went in his place. It came out in the evidence that both had been attending cases of puerperal fever previous to their seeing the deceased. The jury found that death had resulted from puerperal fever, but how she had contracted that disease there was not sufficient evidence to show. They were, however, of opinion that the conduct of the doctor in attending deceased in her confinement and at the same time attending persons suffering from puerperal fever, was highly unsafe and improper. This is one aspect of the case; but there is another not shown. In poor neighbourhoods often very pressing demands are made upon the practitioner as regards midwifery attendance, and if engaged to a case he feels bound to attend, while if he neglects he is equally open to censure from a coroner's jury should any untoward event take place. The moral is that young practitioners, in attending cases, should be more careful of risk to their patients and themselves.

THE VOLUNTEER REVIEW AT GOSFORTH.

A meeting of the Volunteer medical officers has been held in Newcastle, when it was unanimously resolved to form a complete bearer company of the ambulance detachments of the different corps taking part in the review at Gosforth-park on Whit Monday; and to march past in bearer company formation. This is the first bearer company that has paraded at a review in the north. Surgeon-Major Frazer, A.M.D., from the depôt, occupied the chair at the meeting, when it was stated that the general commanding the district would inspect the Gosforth Corps, of whom from 7000 to 8000 volunteers will be present. It may not be amiss to mention an incident which occurred here at a former review, as showing that some little discrimination is desirable in giving tickets to those who are appointed to fall out as wounded and requiring ambulance attention. A corporal was found as wounded, and the bearers from his ticket saw that it was a case of gunshot wound of the leg, and that the corporal would have to be carried to the ambulance tent in the rear, and at a considerable distance. The corporal, whose "fighting weight" was nearly 20 st., was duly and carefully rolled on to the stretcher; but the bearers, being slight lads, found that they could make no progress with their burden, while the "wounded," thinking it rather dull, picked up his rifle and ran back to the ranks.

DEATH OF DR. BOWMAN.

The death of Dr. H. O. Bowman, of Sunderland, has deprived that borough of a well-known physician and magistrate. Dr. Bowman, who was in his sixty-sixth year, had been ailing for some time, but it was not until about a week ago that his illness assumed a serious character. On the 22nd ult. he was known to be in a sinking state, and he died on the following Thursday night. The deceased was a native of Carrickfergus, near Belfast, and had been in practice at Sunderland for forty years, first coming as an assistant to the well-known Dr. Clanny; afterwards he commenced practice on his own account. About eighteen years ago he gave up general practice, but continued acting as a physician until quite lately. He was consulting surgeon to the Royal Albert Asylum, Lancaster, and also a consulting surgeon to the Sunderland Infirmary.

A VERY "CURIOUS" CASE.

"Vomiting an Ask." Under this heading a paragraph has appeared in the *Alnwick Herald*, stating that a boy, aged ten, fell ill about three months ago. He lost appetite and became very weak and emaciated, being at one time treated for gastric fever, but all to no avail until a local practitioner was called in, and he at once administered an emetic, which resulted in bringing forth from the boy's stomach a full-grown newt, locally termed an "ask" (*asker*). Since then the boy has completely recovered health, and has "never looked behind him." I make no comment on the case further than to say that country editors sometimes swallow "queer" things.

Newcastle-on-Tyne, April 20th, 1885.

EDINBURGH.

(*From our own Correspondent.*)

UNIVERSITY GRADUATION IN ARTS.

ON Wednesday, April 22nd, the annual graduation ceremonial in the Faculties of Arts, Law, and Divinity took place. Honorary degrees were conferred upon several distinguished scholars and authors, amongst whom were M. Renan (conferred *in absentia*), Mr. Leslie Stephen, Mr. Theodore Walrond, and Dr. C. J. B. Williams.

ANNUAL ADDRESS: UNIVERSITY REFORM.

After the formal ceremony of "capping" the graduates was concluded, Professor Crystal delivered an address dealing chiefly with the subject of University Reform, and advocated the adoption of open teaching within the University. Each subject, he said, should be taught by additional teachers as well as by the ordinary professor, and these should be recognised as professors extraordinary or as *privatim docentes*, with a definite academic position. This he would wish carried out in all the Faculties in the University; and the intra-academical competition thus produced would obviate the necessity for an extra-academical school. The provision of *increased scope for extra-mural teaching* he deprecated on the ground that its main object would be to prepare candidates for examination, and it would thus inevitably bear upon it the stigma of a cramming system. Professor Crystal's reasoning may, and probably does, bear cogently upon the case of an Arts or Philosophical Faculty, but it is directly at variance with what long experience has proved to be the best arrangement in the Faculty of Medicine. The greatest teachers of whom Edinburgh can boast were extra-academic lecturers at one part of their career, and in most cases made their fame as such; and the extra-mural school has kept up the name of Edinburgh as a popular seat of learning during periods when the light within the University was darkness. The historical argument tells strongly against Professor Crystal's view, and it is to be feared that his system, applied in however broad a spirit to the Faculty of Medicine, would not prevent temporary diminutions in the lustre which the present keen competition outside tends to preserve within the University. A plea for the extension of the extra-mural system of teaching under the provisions of the Universities (Scotland) Bill has already been urged by the Edinburgh University General Council Association, and similar representations were recently made to the Lord Advocate by representatives of the corresponding Association of Glasgow University.

ST. ANDREWS AMBULANCE ASSOCIATION.

At a meeting lately held, the Edinburgh branch of the St. Andrews Association gave a series of practical demonstrations of the work carried on under its auspices. The necessary evolutions for the resuscitation of the drowned, the temporary treatment of fractures and other injuries, and a number of ingenious methods of transporting the injured were put into practice by the trained students of the Association before a large and enthusiastic general audience.

UNIVERSITY EDUCATION FOR WOMEN.

In presiding recently at a meeting of the Edinburgh Association for the *University Education of Women, the* Countess of Aberdeen referred to the presence of clauses in the Universities Bill enabling the Scottish Universities to provide for the graduation of women, and congratulated the Association upon the results of the work which it has carried on in the same direction.

IRELAND.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The annual election for examiners of this College takes place the first Tuesday in May; but on this occasion the Council, in order to obtain the new supplemental Charter, which is now in the hands of the Lord Lieutenant, have at a recent special meeting adjourned it to the 19th, or the third Tuesday in the same month. By the new Charter lecturers attached to medical schools will now be eligible for examiners. No examiner for the future is to hold office for more than three consecutive years, and if he engages in private teaching his election will be null and void. It is understood that not more than two teachers connected with any one school or hospital will be eligible to obtain seats on the Board of Examiners. These alterations are just and proper, and, by providing for a more frequent change in the composition of the Courts of Examiners, will do away with the long-existing evil. Rumour has it that one or more members of Council under the new regulations will be candidates for examinerships, and if so they must previously resign their seats as councillors. The annual elections for President and Council will take place early in June. Among other candidates for seats in the Council will be Dr. Edward Hamilton, Professor of Surgery in the Medical School of the College, who, it is needless to say, will be duly elected.

VISIT OF THE PRINCE OF WALES.

Among the numerous addresses presented to the Prince and Princess of Wales during their visit to Belfast was one from the President and Professors of the Queen's Colleges, and another from the members of the Ulster Medical Society. In that from the College it was remarked that it was the first University College in Ireland to admit women to its classes. The Prince having replied, Miss Everett, mathematical scholar of the Royal University of Ireland, on behalf of her fellow-students, presented a bouquet to the Princess, in recognition of the interest evinced by Her Royal Highness in the higher education of women. The visit of the Prince of Wales to this country has been a most successful one; but I regret to have to add that two members of our profession conducted themselves in a manner unworthy of their education and social position. Dr. Charles Tanner of Cork, for the part he took among a disorderly mob on the occasion of the visit of the Prince, has received an intimation from the secretary of the Royal Cork Yacht Club at Queenstown that it is the intention of the members to propose his expulsion from the Club. The other person is a Dublin surgeon, who had a black flag attached to his residence during the visit. It is gratifying to note that this conduct has met with a well-merited rebuke, for at a meeting of a Medical Society last week, on his commencing to read a paper, almost all present rose *en masse* and left the room, to express their disapproval of his conduct.

UNIVERSITY OF DUBLIN.

In consequence of the death of Earl Cairns, Chancellor of this University, an election of a successor will take place early in May. The Board have submitted the following to the Senate for their selection: viz., the Earl of Rosse, the Marquis of Waterford, and the Earl of Milltown.

A FOOLISH HOAX.

A very stupid trick was played by some person who inserted in the obituary column of a Dublin newspaper this week a statement to the effect that Mr. Wheeler, a hospital surgeon well known in this city, had died last Sunday. As Mr. Wheeler is still in good health, it is to be hoped that the perpetrator of this hoax will be discovered and punished.

DUBLIN HOSPITAL SUNDAY FUND.

Before leaving Dublin the Prince of Wales handed the [illegible] Royal [illegible] 100 guineas, in order to be lodged to the account of the Hospital Fund for 1885.

As regards the statue in memory of the eminent lithotomist, Mr. William Dease, to which I alluded last week, I may add that it will be placed in the entrance hall of the Royal College of Surgeons, and probably will represent Mr. Dease seated instead of standing, as the height of the hall is not such as will permit the latter position.

Dublin, April 28th, 1885.

THE ROYAL COLLEGE OF PHYSICIANS.

At a Comitia of the Fellows of the College, held on Thursday (30th ult.), Dr. Frederick Farre, Vice-President, in the chair, a large number of Members were duly elected to the Fellowship of the College. (The list is published on another page.)

On the motion of the President, an honorarium of 100 guineas was unanimously voted to Dr. Ord in recognition of his services as Secretary of the Committee and Editor of the Revised Edition of "The Nomenclature of Diseases."

A Report from the Council respecting the Croonian Trust was, after some discussion, received and ordered to be circulated. Owing to the great increase in the sums received under this Trust, it is proposed to take steps to obtain permission to extend its application beyond the payment of an annual lecturer.

A recommendation was adopted from the Committee of Management of the Examining Board for England to the effect that the regulations applicable to the admission of candidates from the English Universities be extended to such of the Scotch and Irish Universities as require a residence of at least two years at the University: and that the Colleges retain the right to withhold such privilege if the examination of any University fail to come up to a certain standard. It was also resolved to accept the diploma of M.D. of the University of Toronto as qualifying for admission to the Membership Examination.

A report of a committee appointed to consider the question of publishing Harvey's manuscript lectures was received, and its consideration adjourned.

On the motion of Dr. Wilson Fox, the College appointed a committee to advise as to steps to be taken with reference to the signing of lunacy certificates.

SHIRLEY MURPHY TESTIMONIAL.

FIRST SUBSCRIPTION LIST.

Samuel Morley, Esq., M.P.	£10	0	0	Dr. James Wakley	£2	2	0
Dr. Cayley	2	2	0	R. F. Charles, Esq.	1	1	0
Dr. Jas. F. Goodhart	1	1	0	Dr. E. Seaton	1	1	0
Dr. Thos. Barlow	1	1	0	W. Ash, Esq.	5	5	0
Rev. A. Godson	1	1	0	Miss E. S. Ledgett	1	1	0
William Wilson, Esq.	2	2	0	J. Whitcher, Esq.	1	1	0
Chas. Wilson, Esq.	1	1	0	Jas. Fraser, Esq.	1	1	0
William Hickson, Esq.	1	1	0	T. F. Gandar, Esq.	2	2	0
Dr. J. G. Glover	2	2	0	Miss Gandar	1	1	0
Thomas Wakley, Esq., *jun.*	1	1	0	J. A. Hexton, Esq.	2	2	0
J. W. Gandar, Esq.	2	2	0	W. Adams, Esq.	1	1	0
John Hamer, Esq.	2	2	0	G. C. Ash, Esq.	21	0	0
Isaac Butler, Esq.	1	1	0				
A Well-wisher	5	0	0	Berkeley Hill, Esq., F.R.C.S.	2	2	0
Lady Henry Somerset	21	0	0	John Faulkner, Esq.	2	2	0
P. Banting, Esq.	1	1	0	Thos. Reynolds, Esq.	1	1	0
A Friend	15	0	0	*Morris Lewis, Esq.*	1	1	0
J. Northcote Vince, Esq.	1	1	0	Thomas Wakley, Esq.	2	2	0

The Executive Committee wish it to be understood that the smallest contributions are acceptable.

MEDICAL NOTES IN PARLIAMENT.

Cremation.

In the House of Lords on the 24th ult., the Earl of Dalhousie, in reply to the Earl of Onslow, stated that he did not quite know what the powers of the Government in the matter of cremation were. Some time ago they were asked to legislate with the view of regulating the practice of cremation by certain safeguards, but the Secretary of State thought at that time that the people of this country were not the least inclined to adopt it as an [illegible] of disposing of the dead. He would endeavour to ascertain what the views of the Secretary of State now were.

Lunacy Acts Amendment Bill.

On the 27th ult. the Lord Chancellor moved the second reading of the Lunacy Acts Amendment Bill. The Earl of Milltown, in supporting the Bill, thought it was to be regretted that the Government had not seen their way to vesting compulsorily private licensed houses in some public body, and thus get rid of that most objectionable element, profit. As long as the profitable system was allowed to continue he feared the public would never be altogether satisfied. At any rate he hoped this Bill would eventually and speedily lead to the total suppression of the system. Again, there was an absence of any provision that the proprietors of these houses should be properly qualified and fit persons; that was a point which was well looked after in other countries, and he thought it ought to be provided for in the Bill. Then, again, the Bill contained no provision that the medical officers should be independent persons, and that was a deficiency which he thought ought to be supplied. He could not understand why the Bill did not extend to Ireland. The lunacy laws of Scotland differed materially from those of England, and he could therefore understand why the Bill should not extend to Scotland; but there was very little difference between the law in England and in Ireland, and consequently he thought the Bill ought to include Ireland. The Bill was read a second time; and a Bill for consolidating the laws relating to lunacy was read a first time.

Rags and Small-pox.

In the House of Commons on the 23rd ult., the Lord Advocate, in reply to Dr. Farquharson, stated that he had communicated with the Board of Supervision in regard to the recent occurrence of two cases of small-pox among workers in the Woodside Rag Works, and that the attention of the Board has been directed to the fact that small-pox on more than one occasion had occurred among the operatives in the works referred to, and others. There could be no doubt that in some of these cases the infection had been traced to rags imported from abroad, as well as to the rags collected in this country. The Board's medical officer had made inquiries at the instance of the Board, but as it appeared very doubtful whether, under the Public Health Act, the Board could compel the papermakers to disinfect the bundles of rags before being used, the Board had mainly directed the attention of the local authority to the importance of making provision for the isolation and treatment of the infected persons, so as to prevent the spread of the disease.

The Custody of Lunatics.

On Thursday, Sir W. Harcourt, in reply to Mr. W. Corbet, who asked if his attention had been called to several cases recently reported, in which workhouse authorities refused to receive, even temporarily and pending inquiry, wandering insane persons for whom reception orders were duly made by police magistrates, said that he was clearly of opinion that the proper place for those poor unfortunate persons was neither the police cells nor the gaols, but the workhouse; but great difficulties had been raised by the workhouse authorities. He trusted to be able to insert a clause in the Lunacy Bill, now before the House of Lords, that would clear up the matter.

Obituary.

PAUL BENNETT CONOLLY,

SURGEON, ARMY MEDICAL STAFF.

This young medical officer, as we announced last week, died near Korti, on the Nile, of enteric fever, at the age of thirty. The news will cause great grief to a wide circle of friends, and at Charing-cross Hospital (his old school) his untimely death has produced a universal feeling of dismay and sadness. All who knew him predicted for him a brilliant future, and some account of what he has done is here appended. His first experience of war service was in the Russo-Turkish campaign at Bucharest, and he was present at the final attack upon Plevna. He was decorated by the King of Roumania with the Gold Cross. He next volunteered for service at the Cape during the last Zulu war, and was with Sir E. Wood in the many engagements preceding that of Kambula, taking part in the attacks on the Zlobani Hill and in the battles of Kambula and Ulundi. He was mentioned in dispatches for his gallantry at the Zlobani Hill, and at the end of the war received the medal and clasp. On returning to England he determined to enter the Army, and shortly after finishing his course at Netley was sent in command of a bearer company to the Cape during the Boer war. His next active duty was in the Egyptian campaign of 1882, where he was surgeon to the 2nd Bearer Company, and was present at the battles of Kassassin and Tel-el-Kebir, receiving the medal and clasp and Khedive's star. After his return he read for the Primary F.R.C.S., which examination he passed in May, 1884, holding at the time the appointment of Assistant Instructor to the Army Hospital Corps at Aldershot. When the relief of Gordon was determined on he volunteered his services, and was appointed to the light division of the Camel Corps, and has during the campaign been mentioned more than once in flattering terms by those who saw his arduous work between Korti and Gakdul. He was a typical specimen of the soldier-surgeon; pleasant, light-hearted, though sensitive to a degree, he combined a brave heart with a steady hand and a winning manner, with all the highest and essential qualities of a thorough surgeon.

STEPHEN HEMSTED, M.R.C.S.

Mr. Stephen Hemsted, whose death occurred recently at Newbury, Berks, was the eldest son of Henry Hemsted, M.D., many years coroner of the borough of Newbury; grandson of Stephen Hemsted, M.D., of Ilsley Hall, one of the coroners for the county of Berks; and great-grandson of Stephen Hemsted, surgeon, of Haverhill. He was born in 1802, and obtained his professional education under Mr. Abernethy at St. Bartholomew's Hospital. In 1825 he obtained the diploma of Membership of the Royal College of Surgeons of London, and commenced practice in Newbury, where he soon acquired an extensive reputation. Mr. Hemsted was universally respected throughout the district in which he resided, and will be long regretted by those who had the pleasure of being intimate with him.

JOHN CAUNT, M.R.C.S.

We have to record the death of Mr. John Caunt, who for many years resided and practised as a surgeon at Wheeler Gate, Nottingham. He left Nottingham in 1856, and some time after was appointed by the chief inspector of factories, A. Redgrave, Esq., C.B., to a district in London. He discharged the duties of this office faithfully to within a short time of his death. The deceased gentleman was greatly esteemed by a large circle of friends and patients, by whom the announcement of his death will be received with regret, though he had attained the ripe age of eighty-two years. Mr. Caunt died on the 19th ult. at Dudley-place, St. Mary-terrace, Paddington, and was buried at Great Willesden.

Medical News.

Royal College of Physicians of London.—The following Members have been elected Fellows of the College:—

Carter, William, M.B. Lond., Liverpool.
Davidson, Alexander, M.D. Edin., Liverpool.
Smith, Thomas Gilbart, M.D. Dub., Harley-street.
Herman, George Ernest, M.B. Lond., West-street.
Finlay, David White, M.D. Glas., Montagu-street.
Skerritt, Edward Markham, M.D. Lond., Clifton.
Bennett, Alexander Hughes, M.D. Edin., Queen Anne-street.
Sangster, Alfred, M.B. Camb., Savile-row.
Semon, Felix, M.D. Berlin., Welbeck-street,
Harris, Vincent Dormer, M.D. Lond., Welbeck-street.
Ormerod, Joseph Arderne, M.B. Oxon., Upper Wimpole-street.
West, Samuel Hatch, M.D. Oxon., Wimpole-street.
Smith, Robert Shingleton, M.D. Lond., Clifton.
Smith, David Boyes, M.D. Edin., Netley.
Savage, George Henry, M.D. Lond., Bethlehem Hospital.
Thorburn, John, M.D. Edin., Manchester.
Owen, Herbert Isambard, M.D. Camb., Gloucester-gardens.
Carrington, Robert Edward, M.D. Lond., St. Thomas's-street.
Kidd, Percy, M.D. Oxon., Brook-street.
Sharkey, Seymour John, M.B. Oxon., Portland-place.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 23rd ult.:—

Arnold, William, L.S.A., Hale, Altrincham.
Hayes, Julian Philip Swindell, L.K.Q.C.P.I., Tavistock-crescent.
Collins, George Fletcher, L.K.Q.C.P.I., Dublin.
Barendt, Frank Hugh, L.R.C.P. Lond., Liverpool.
Fowler, Thomas Webb, L.S.A., Matlock.
Carrington, George Hedwig, L.S.A., Eccles.
Hughes, Samuel, L.S.A., Liverpool.
Robson, Herbert John, L.R.C.P. Ed., Leeds.
Crosby, Robert, L.S.A., Sunderland.
Armstrong, Leonard Henry, L.S.A., Cambridge-street.
Brown, Thomas Alexander, M.B. Edin., Edinburgh.
MacLaren, Murray, M.B. Edin., Edinburgh.
Barwise, Sidney, L.S.A., Birmingham.
Smith, Franke Chamberlain Hart, L.S.A., Bedford.
Cooper, Chas. Bolingbroke, L.R.C.P. Lond., Liverpool.
Hubbersty, Robert Stephen, M.B. Edin., Stamford.

Admitted on the 24th ult.:—

Whitwell, Alfred Frank, L.S.A., Shrewsbury.
Hodgson, Gerald George, L.S.A., Brighton.
Matthey, Arthur, L.R.C.P. Ed., Southampton.
Hunter, George Holbrey, L.S.A., Frohlake, near Doncaster.
Strong, Henry Barlow, L.K.Q.C.P.I., Bernard-street.
Hebblethwaite, Septimus Montague, L.S.A., Moor Allerton.
Crowdy, Francis Demainbray, L.S.A., Harcourt-buildings.
Scott, Bertal Hopton, M.D. Toronto, St. Peter's-road.
Joberns, William, L.S.A., Walsall.
Cockerill, John William, L.R.C.P. Lond., Portsdown-road.
Simpson, James Tracy, L.R.C.P. Ed., Approach-road.
Cook, Henry Samuel, L.S.A., Birmingham.
Beater, Orlando Palmer, M.B. Dub., Dublin.
Melson, George Hyde, L.S.A., Knowle, Warwickshire.
Wigam, William Harper, M.B. Durham, South Shields.
Hall, Gilbert Capel, L.S.A., Birmingham.
Fisher, Thomas Hammond, L.S.A., Southport.
Wakefield, Mark Joseph, M.B. Durham, Gateshead.

Admitted on the 25th ult.:—

Blakeney, Hugh Theophilus Weare, L.A.H. Dub., Dorking.
Evans, Robert, L.R.C.P. Ed., Granville-square.
Basset, Walter, L.R.C.P. Lond., Bristol.
Lysaght, William Connor, L.R.C.P. Lond., Bristol.
Kendall, Hy. Wm. Martindale, L.S.A., Bexley Heath.
Brooks, Jabez Pratt, L.S.A., Torrington-park.
Barnett, Lawrence, L.S.A., Swansea.
West, Charles James, L.R.C.P. Lond., Warwick-street.
Failes, Frederick George, L.S.A., Kings Lynn.
Baker, George Henry, L.S.A., Argyll-road, Kensington.
Brito, Philip Sebastian, M.B. Aberd., Ceylon.
Edginton, Alfred Dudley, L.S.A., Southampton.

Admitted on the 27th ult.:—

Browne, Harold Elliott, L.R.C.P. Lond., Wisbech, Cambs.
Hanson, Albert George, New South Wales.
Morgan, Edward Hume, New South Wales.
Harries, John Frail, L.S.A., Shrewsbury.
Davis, Edward Sandom Stone, L.S.A., Fowey, Cornwall.
Rothera, Frank, M.B. Ed., Nottingham.
Green, Chas. Robt. Mortimer, L.S.A., Morpeth-street.

Admitted on the 28th ult.:—

Blight, John Henry, L.R.C.P. Lond., Sladesbridge.
Cayley, Guthrie Neville, L.R.C.P. Lond., Windsor.
Booth, William Henry, L.R.C.P. Lond., Plymouth.
Smith, Frederick John, L.R.C.P. Lond., Bishopsgate.
Maynard, Frederic Pinsent, L.R.C.P. Lond., Barnes.
Walsh, Charles Lawrence, L.R.C.P. Lond., Oxford.
Armstrong, Hugh, L.R.C.P. Lond., Chalcot-crescent.
Tanner, Herbert, L.R.C.P. Lond., Bicester.
Creasy, Rolf, L.R.C.P. Lond., Ealing.
Garmany, Jasper Jewitt, M.D., Bellvue, Savannah, U.S.A.

Admitted on the 29th ult.:—

Nutting, Philip Henry, L.R.C.P. Lond., Warwick.
Woolmer, Shirley Lawrence, L.S.A., Charrington-street.
Wood, Edward, L.S.A., Tottenham.
Barrett, William Peard, L.S.A., Cheltenham.
Pedler, William Frederick, L.S.A., Tiverton.
Simmons, Harold, L.S.A., Ladbroke-grove-road.

The following candidates passed the Primary Examination in Anatomy and Physiology for the diploma of Member of the College at a meeting of the Board of Examiners on the 16th ult.:—

Anatomy and Physiology.—G. Oliver Richards and R. Baxter Booth, Charing-cross; Arthur Gervase Hendley, Arthur Bentham, and W. G. S. Brown, St. Bartholomew's; Jeremiah Penny, King's College; J. Albertus Exton and S. J. Cole, London; Cyril S. Davis, A. E. Poolman, W. E. Tressider, W. G. Brett, and J. E. Moyse, Guy's; A. J. Moss, Manchester; L. W. Powell, University College; Charles S. Vines, E. Lycett Cropp, and G. J. Harris, Westminster; C. F. Rilot and W. H. Charles, Middlesex; J. H. Fardon, Bristol; F. W. Parker, A. H. Ward and E. Le Cronie Lancaster, St. George's; J. C. Barr, St. Mary's; R. F. Walker, St. Thomas's.

Anatomy only.—Albert Pearse, St. Bartholomew's; E. Stock Bell, St. Thomas's.

Physiology only.—J. L. Johnston and C. H. Smale, Manchester; J. D. O'Sullivan, Dublin; H. B. Seddon, St. Thomas's; J. R. Gallard, London; A. Norman, Guy's; Frank Gilpin, Middlesex; H. Hanlton Coates, St. Bartholomew's.

(Candidates referred for three months, 2; six months, 4.)

Passed on the 17th ult.:—

Anatomy and Physiology.—W. H. Cooper, W. Wallis Ord, C. H. James, J. H. Lotlz, Frank Fowler, and H. H. Heffernan, St. Thomas's; H. W. Lewis, C. T. Boodlee Maltey, W. Wilfred Williams, Lewis Brown, G. L. Kemp, and Arlingham Carter, Guy's; C. Charan, Sen., and Charles Duer, University College; T. H. Clarke and John Maberly, Middlesex; Nugent E. Smyth, Birmingham; John Norton, Westminster; C. W. Ensor and W. Gostwyck Sargent, London; W. Byam Lane and T. Lakeman, St. Bartholomew's; S. E. Pedley, Charing-cross.

Anatomy only.—J. Mackenzie Bremner, King's College; W. H. F. Godwin, Westminster; Samuel H. Hughes and Frank Heasman, St. Bartholomew's; Nicholas Tyacke, Middlesex; G. H. Trenfield, Bristol; H. Cockerton, St. George's; G. R. Anderson, St. Thomas's.

Physiology only.—F. Price Drury and A. F. Tyrrell, Middlesex; T. Warne Sargent, London; P. Allison Linnell, Manchester; C. B. Seal, University College.

(Candidates referred for three months, 3; six months, 3.)

Passed on the 18th ult.:—

Anatomy and Physiology.—T. J. Dabell, W. Griffith Williams, T. E. Spencer, and Reginald Martyn, St. Bartholomew's; John Forster, William Powell, W. A. T. Twemlow, and A. H. W. Hunt, Westminster; J. Porter Parkinson, E. B. Hastings, R. Foster Gill, and J. E. Gould, University College; Charles H. Eccles, St. Thomas's; W. Heatley, Ernest Baly, and A. B. Davies, London; H. Carlos Barr, St. Mary's; W. J. Radford and J. G. V. Sapp, Charing-cross; G. C. B. Atkinson and W. Gifford-Nash, Middlesex; F. W. Pearce, Guy's.

Anatomy only.—Albert Lucas and C. R. B. Alexander, St. Bartholomew's; Edwin Webster, St. Thomas's; F. J. Oxley, London.

Physiology only.—F. J. Brown, Middlesex; J. S. Part, Westminster; G. T. Mould, St. George's.

(Candidates referred for three months, 6; six months, 1.)

Passed on the 20th ult.:—

Anatomy and Physiology.—L. T. F. Bryett, H. R. Henley, King's College; E. A. Snape, Charing-cross; E. O. Ashe and F. G. Twigg, London; G. Seymour and E. E. Lewis, Middlesex; R. A. Sawyer, Guy's; Charles J. Weekes, University College; C. W. Cooke, St. Thomas's.

Anatomy only.—G. John Cressy and R. Teale Wallace, Guy's.

Physiology only.—J. Conyers Bell and W. G. Thorpe, Guy's; Isaac G. Modlin, Newcastle.

(Candidates referred for three months, 3; six months, 5.)

[In the list of candidates who passed in Physiology on the 15th ult., for "Cartmil" read Cartmel.]

The Library of the College will be closed on Monday, Tuesday, and Wednesday, 4th, 5th, and 6th of May, at 4 P.M. each day, for the purposes of the examination in Medicine and Midwifery for the diploma of Member; and on Friday, May 8th, for the Primary Examination, 156 candidates having entered for that examination.

University of Durham.—At the recent examinations for the certificate of proficiency in Sanitary Science, the following satisfied the examiners:—

Roberts, James Reid, M.R.C.S., L.R.C.P.
Walker, Charles Pope, M.R.C.S.

For the above examination only two candidates entered. For the first examination for the degree of Bachelor of Medicine, of sixty candidates thirty-two satisfied the examiners.

University of St. Andrews.—The following registered medical practitioners having passed the required examinations, the degree of M.D. was conferred on them on April 24th:—

Anderson, John, M.R.C.S., L.S.A., Brigade-Surgeon Half-pay, London.
Davidson, Chas., M.R.C.S., F.R.C.S. Ed., L.K.Q.C.P.I., London.
Fenn, Edwin, M.R.C.S., L.S.A., Dover.
Knott, Sydenham John, M.R.C.S., L.S.A., London.
Marriott, Charles W., F.R.C.S. Ed., M.R.C.S., L.S.A., Surgeon-Major, A.M.D., Leamington.
Morgan, George, M.R.C.S., L. R.C.P. Ed., L.S.A., Pontypool.
Skelton, Henry, M.R.C.P. Ed., M.R.C.S., Downend, near Bristol.
Stott, William John, M.R.C.S., L.R.C.P. Ed., Haslingden.
Wickham, Richard Henry Brenton, F.R.C.S. Ed., F.R.C.P. Ed., Newcastle-on-Tyne.

The following gentleman also proceeded to the degree of M.D.:

Lowe, George, M.B., C.M. St. Andrews, Wymondham.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the final examination for the triple qualification granted by the above-named bodies:—

Gordon, A. S., M.A., Edinburgh School.
Hill, Andrew, Glasgow School.
Laing, J. B., Glasgow School.
Spittel, Frederick George, Ceylon Medical School.

Faculty of Physicians and Surgeons of Glasgow. The following candidates passed the Final Examination at the April sittings of the Examiners, and were admitted Licentiates:—

Clark, S. P., Glasgow Royal Infirmary.
Modder, Eugene, Ceylon Medical College.
Malcolmson, John F., Dublin and Glasgow.
Plummer, Ed., King's College and Glasgow.
Rugg, J. Foster, L.R.C.P. Edin., St. Thomas's Hospital
Somerville, Wm., Anderson's College.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At meetings of the Court of Examiners held on April 7th and following days, the undermentioned obtained the diploma in Surgery of the College:—

Alfred George Beale, Jeremiah Beahan, Louis Aloysius Byrne, Robert George Christy, Thomas Codd, James Corcoran, Edward George Cotton, Patrick James Curtin, John Cuthbert William Daune, John Joseph Davoren, John Dawson, John Empson, Frederick Hall, Michael St. Lawrence Harford, Patrick Heelan, Arthur Joseph Hogan, George Edgar Hughes, John Keany, Henry T. Knaggs, David Humphreys, Reginald Levinge, Daniel McCann, James Douglas McDonagh, William Arthur Mahon, Matthew John Marmion, John O. Callaghan, John Rogers, William John Russell, Edmond Aloysius Ryan, Jeremiah B. Ryan, John Joseph Savage, James Albert Frederick Sawyer, Robert Dudley Alger Stone, Ernest Hastings Tweedy, Thomas F. Wade, Hugh Whelan, and John Whyte.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 23rd ult.:—

Gifford, George Taylor, King's College.
Hillier, Thomas Ernest, St. Bartholomew's Hospital.
Ritchie, Edward Duguid, St. Thomas's Hospital.

A TELEGRAM from Dongola announces the existence of an epidemic of small-pox at Omdurman.

WOOTTON WARREN, a small village near Leamington, with 700 inhabitants, is credited with having living in it seven persons whose united ages amount to 651 years, or an average of ninety-three years each.

A PORTRAIT of Dr. Fordyce Barker has been presented to the New York Academy of Medicine. The portrait, by Lazarus, represents the ex-president of the Academy in his Edinburgh academical robes, and is said to be an excellent likeness.

AT the Guildhall on the 29th ult., a butcher of Burgess-hill was sentenced to six weeks' imprisonment, without the option of a fine, for having sent four quarters of diseased meat to the London market, the same being unwholesome and unfit for human food.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—The next meeting will be held at the rooms of the Social Science Association, Adam-street, Adelphi, on Saturday next, May 2nd, at 6 o'clock P.M. An address will be delivered by the President, Mr. Edwin Chadwick, C.B., entitled (probably) "A Review of the past Session."

AT a meeting of the Paddington Vestry on the 21st ult., it was decided, previous to affixing the seal of the Vestry to the contract for a new sewer, to obtain the opinion of a sanitary expert as to whether the sewer is required, whether it should be a brick or glazed stoneware pipe sewer, and what provision should be made for the ventilation of the sewer recommended.

THE METROPOLITAN ASYLUMS BOARD.—At the meeting of the managers of this Board on the 25th ult., another serious outbreak of small-pox in the metropolis was reported. The disease had a short time ago decreased to such an extent that it had been proposed to close the Western (Fulham) and North-Western (Hampstead) Hospitals, the wards of which were empty. In four weeks, however, no less than 874 cases have come into the hands of the medical officers, and there are now 1039 patients in the eight asylums. The motion for the closing of the two asylums mentioned was accordingly withdrawn.

AT a meeting of the City Commissioners of Sewers on the 28th ult., the Sanitary Committee presented a report stating that they had from time to time considered the question of the advisability of erecting a crematorium that the public might adopt that mode of sepulture should they so wish, and, in order to acquire every information on the subject, they requested the Court's authority to visit some place where the system was in operation, so that they might witness the cremation of a human body. Rome, Milan, or Gotha, were the places to one of which the Committee wished to proceed. The report was negatived by a large majority.

MIDLAND MEDICAL SOCIETY: PRESENTATION TO MR. HARMAR.—At the last meeting of the session, held at the Birmingham Medical Institute on Wednesday, April 22nd, Mr. Harmar, the late treasurer of the Society, who had held that office for eighteen years, was presented with a handsome timepiece, a pair of silver candlesticks, and an illuminated address, subscribed for by 163 members. The President (Mr. T. H. Bartleet), in making the presentation, spoke of the great services Mr. Harmar had rendered to the Society. The address, which was beautifully illuminated, was as follows: "To James Harmar, Esq., M.R.C.S., L.S.A. Dear Sir,—The members of the Midland Medical Society, on your resignation of office as treasurer, are desirous of expressing their sincere appreciation of the zeal, ability, and success with which you have discharged the duties of that office during a period of eighteen years." Affixed to the clock was a plate with an inscription also testifying to Mr. Harmar's valued services.

OXFORD GRADUATES' MEDICAL CLUB.—The chair at the next dinner of this Club is to be taken by Dr. John W. Ogle, of Trinity College, and, it being the anniversary meeting, only members of the Club will attend. The dinner is to take place on Thursday, May 21st, at 7.30 P.M., at Limmer's Hotel, George-street, Hanover-square. It will be remembered that the Club was started only last year, and it already numbers more than one hundred members, a very large proportion of these practising medicine or surgery and holding Oxford degrees. The Secretaries are Dr. Samuel West and Mr. J. H. Morgan, and those intending to be present should forward their names to one of these gentlemen.

HOSPITAL SUNDAY AT ROCHESTER.—Hospital Sunday has been observed as usual in Rochester and Chatham by the Mayor and Corporation attending the Cathedral in state. There were large congregations at both services, as well as at other places of worship in the neighbourhood where sermons were preached in behalf of the fund. At St. Bartholomew's Hospital, Chatham, more than 12,000 patients have received treatment during the past year, and these have come from sixty-one different parishes. The superintendent of St. Paul's Sunday School, writing to the local press, says that by encouraging children to bring their pennies on Hospital Sunday he has collected seventeen or eighteen shillings a year for the fund, and he suggests that this plan might be generally adopted in Sunday schools belonging to both churches and nonconformist places of worship, with the result of considerably augmenting the collections already made.

UNIVERSITY OF CAMBRIDGE.—The preliminary notice of the dates of the examinations for Medical and Surgical Degrees, for Easter term, 1885, has been issued. For the degree of Bachelor of Medicine, the first examination will begin on June 5th, the second on June 9th, and the third (Parts I. and II.) on May 12th and 13th; for the degree of Bachelor of Surgery, on May 16th; for the degree of Master of Surgery, on May 15th and 16th. The names of candidates for the third examination and for the examinations in Surgery must be sent to the prælectors of their respective colleges on or before May 4th; those for the first or second examinations on or before May 26th. The certificates of candidates, accompanied by their postal addresses, must be sent to the Secretary, not less than seven days before the beginning of the examination for which they are entered. The fees for the examination must be paid to the Registrar of the University before the certificates are sent in.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BAKER, THOMAS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District of the Havant Union.

BENNETT, E. A., L.R.C.S.Ed., L.S.A.Lond., L.M.Ed., has been appointed Honorary Surgeon to St. Mary's Cottage Hospital, Southampton, vice Wilme, deceased.

CHAPMAN, GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Yoxall District of the Lichfield Union, vice Ramsden.

FERNANDEZ, EDWARD J., L.R.C.P., L.R.C.S., L.M., has been appointed Medical Officer of Health and Port Surgeon under the Bombay Government at Perim Island, Red Sea, Arabia.

FOORD-CLARK, HARRY, L.R.C.P., L.R.C.S., L.M.Ed., has been appointed Government Medical Officer and Public Vaccinator to the Town and District of Moree, New South Wales.

FOWLER, TREVOR, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Nazeing District of the Epping Union, vice Priest.

HANDFORD, HENRY, M.D., M.R.C.P., has been appointed Physician to the General Hospital, Nottingham.

HELM, ROBERT DUNDAS, M.B. & C.M.Ed., has been appointed Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

MCCRACKEN, JOHN, M.B., M.Ch.Glas., has been appointed Medical Officer for the Kilburn District of the Thirsk Union, vice Stevens.

MACKENZIE, HECTOR WILLIAM GAVIN, M.A., M.B.Cantab., has been appointed Resident Assistant-Physician at St. Thomas's Hospital, vice Percy Smith, M.D., resigned.

MARR, JOSEPH BELL, L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Health Officer for the Shire of Ballan, Victoria.

MYDDELTON-GAVEY, E. H., M.R.C.S. & L.S.A.Lond., has been appointed House-Surgeon at the Leeds General Infirmary.

PARRY, GEO. HALES, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Dorking District and Workhouse, Dorking Union, vice Batson.

POPE, PERCY, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Havant Union.

ROBINSON, ARTHUR HENRY, M.D.Dur., M.R.C.S., has been appointed Medical Superintendent of the Infirmary, and Medical Officer of the Workhouse and Schools, Mile-end Old Town Hamlet.

SMITH, PERCY, M.D., has been appointed Assistant Medical Officer to Bethlem Royal Hospital.

SYMONS, GEO. FRANCIS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Third District of the Newton Abbot Union.

WHITELEY, GEO. WILLIAM, L.R.C.P.Ed., L.R.C.S.Ed., M.R.C.S., has been appointed Medical Officer for the Second District of the Alderbury Union.

Births, Marriages, and Deaths.

BIRTHS.

BEAUMONT.—On the 24th ult., at Shirley, Southampton, the wife of Charles G. Beaumont, M.D., of a daughter.

BUNN.—On the 25th ult., at Ferndale, Upper Norwood, the wife of C. Grinling Bunn, L.R.C.P., M.R.C.S., of a son.

HINE.—On the 23rd ult., at Eppingdale, Leytonstone-road, the wife of A. Leonard Hine, L.R.C.P., M.R.C.S., L.S.A.Lond., of a son.

NORTON.—On the 28th ult., at Upper Gloucester-place, the wife of G. Everitt Norton, M.R.C.S. &c., of a daughter.

STOCKS.—On the 22nd ult., at Courland, Wandsworth-road, London, S.W., the wife of Frederick Stocks, M.R.C.S., of a daughter.

MARRIAGES.

HARE—CUMMINS.—On the 23rd ult., at St. Paul's, Brentford, Evan Herring Hare, M.A., M.R.C.S., son of Evan Hare, of Kew, to Emily Lucy, daughter of the late Richard Norris Cummins, of Mortlake.

HIGGENS—GREENWOOD.—On the 22nd ult., at Titchborne, Hants, by the Hon. and Rev. Everard Arundell (cousin of the bride), Charles Higgens, F.R.C.S., 38, Brook-street, W., Ophthalmic Surgeon to Guy's Hospital, to Evelina, eldest daughter of the late Colonel Greenwood, of Brookwood Park, Hants.

KNOTT—HOLMES.—On the 23rd ult., at St. Andrew's Church, Higher Blackley, near Manchester, by the Rev. E. Parker, William Knott, surgeon, of Waterhead, Oldham, to Aimée, only daughter of E. Holmes, Esq., Boothroyden, Manchester.

MATTHEWS—VEVERS.—On the 20th ult., at Holmer Church, Samuel Richard Matthews, M.D., of Hereford, to Maria Elizabeth (May), youngest daughter of Henry Vevers, Esq., of Highmore House, Hereford.

MACQUEEN—COMBERBACH.—On the 22nd ult., at Huyton Parish Church, Thomas MacQueen, M.B., C.M., of Eastbourne, to Edith Mary, youngest daughter of Robert S. Comberbach, of South Park, Huyton.

MOTT—SOLEY.—On the 22nd ult., at Christ Church, Sefton Park, Liverpool, by the Rev. Henry Coote, A.B., Rector of Donaghadee, Fredk. Walker Mott, M.B., B.S.Lond., to Georgiana Alexander, daughter of the late George Thomas Soley, Esq., of Parkfield-road, Liverpool.

RINGER—RICH.—On the 16th ult., at Hardwicke, Aylesbury, by the Rector, the Rev. W. Bigg-Wither, assisted by the Rev. Newton B. Young, Rector of Tillbrook and Rural Dean, Deputy Surgeon-General Theobald Ringer, late 7th Bengal Cavalry, son of the late William Ringer, Esq., of Laugharne, Carmarthenshire, to Frederica Adela, eldest daughter of the Rev. Henry Rich, Great Alne, Alcester, Warwickshire, and formerly Curate of Hardwicke-cum-Weedon.

DEATHS.

ANDERSON.—On the 28th ult., at Abingdon-road, Mark French Anderson, L.R.C.P.Ed., M.R.C.S., in his 51st year.

BLAKEMORE.—On the 19th ult., at his residence, Montpellier-road, Brighton, William Blakemore, F.R.C.S., late of Grosvenor-street, son of the late William Blakemore, of H.M. Exchequer.

CAUNT.—On the 19th ult., at Dudley-place, Paddington, John Caunt, M.R.C.S., formerly of Nottingham, in his 82nd year.

CRERAR.—On the 1st ult., at the Royal Military Asylum, Chelsea, James Crerar, Deputy Surgeon-General.

DIXON.—On the 25th ult., at Lansdowne-terrace, West Brighton, Joseph Dixon, M.R.C.S. and L.S.A.Lond., aged 62.

DUNCAN.—On the 22nd ult., at 6, Harley-street, Cavendish-square, W., after a few days' illness, Ada Mary, the loving and much-loved wife of William A. Duncan, M.D., F.R.C.S.Eng., aged 28.

EDMONDS.—On the 22nd ult., at Fowey, Cornwall, Fredric Edmonds, M.D., F.R.C.S.E., late of Guanajuato, Mexico, aged 75.

FRANKS.—On the 19th ult., at Billesdon, Leicester, William Francis Franks, M.R.C.S., L.S.A.Lond., aged 71.

GARDINER.—On the 23rd ult., at Wimpole-street, G. G. Gardiner, M.D., also of Finsbury-circus, aged 49.

GLEADALL.—On the 22nd ult., at his residence, St. George's Villa, Sheffield, James Gleadall, F.R.C.S., in his 67th year.

INNES.—On the 23rd ult., at Lyndhurst-road, Hampstead, Surgeon-General Francis William Innes, C.B., aged 73.

WHITELOCK.—On the 27th ult., at Chalcot-crescent, Regent's-park, Surgeon-Major Thomas William Whitelock, in his 70th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 4.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. E. Lloyd Williams, F. I. Hutchinson, W. A. Hunt, David Hepburn, and C. W. Dunn of Florence (per Mr. Storer Bennett, Hon. Sec. Foreign Correspondence).—Dr. W. St. George Elliott: Bridge Work, with Remarks on Electro Motors.

Tuesday, May 5.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Charlewood Turner: (1) Tumour of the Brain; (2) Posterior Sclerosis of the Cord (card).—Dr. Norman Moore: Malignant Disease of the Cranial Bones in a Child.—Dr. Dyce Duckworth: Sarcoma of the Lung and Brain in a Child.—Dr. G. N. Pitt: The Viscera of a Syphilitic Infant.—Dr. Payne: Varicella Gangrenosa.—Mr. Paul: A group of cases of Primary Carcinoma of the Liver.—Dr. Goodhart: Cirrhosis simulating Cancer of the Liver (card).—Mr. Shattock: Actino-mycosis of the Liver (card).—Mr. Bilton Pollard: Callus of Tibia and Fibula.—Dr. Hadden: Chronic Cerebro-spinal Meningitis.—Mr. Sutton: Typhoid Fever in Animals.—Mr. Battle (for Mr. Croft): (1) Primary Sarcoma of the Kidney (card); (2) Fistula between Small Intestine and Bladder (card).—Mr. Doran: Pedunculated Fibroma on the Outer Wall of an Ovarian Cyst (card).—Mr. D'Arcy Power: Three Specimens of an Encysted Hernia (card).—Dr. Percy Kidd: (1) Intercalar Ulceration of the Tongue (card); (2) Small Fibroma of Cæcum (card); (3) Tubercular Ulceration of the Tongue (card) (for Mr. H. H. Taylor).—Mr. Churchill: (1) Congenital Papillomata of Mouth and Neck (card); (2) Acute Ostitis of Tarsus.

Wednesday, May 6.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Horrocks and others.—Dr. Matthews Duncan: On the Ulceration of Lupus of the Female Generative Organs.—Dr. W. H. Day: Case of Uterine Fibroid complicating Labour treated by Enucleation.—Dr. John Williams: On Serous Perimetritis.

Thursday, May 7.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Tyndall: Natural Forces and Energies.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. M. Handfield Jones: Notes on a case of Porro's Operation, with Specimen.—Dr. A. de Watteville: Methods of Electrical Diagnosis in Nervous Diseases.

Friday, May 8.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—2.30 P.M. Council Meeting.—4 P.M. Quarterly Meeting. A resolution will be proposed to express the feeling of the Association on the retirement of Lord Shaftesbury from the Lunacy Commission. The provisions of the proposed Lunacy Amendment Bill.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hadden: A case of Obstruction of the Arteries and Veins extending over many years.—Mr. J. R. Lunn: Osteitis Deformans.—Dr. Cayley: A case of Hæmoptysis treated by the Induction of Pneumothorax so as to Collapse the Lung.—Mr. Charles Symonds: A case in which, at the request of the late Dr. Mahomed, a Calculus was removed from the Vermiform Appendix for the relief of recurrent Typhlitis.

ROYAL INSTITUTION.—9 P.M. Mr. W. F. R. Weldon: On Adaptation to Surroundings as a Factor in Animal Development.

Saturday, May 9.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. W. Carruthers: Fir-trees and their Allies.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

AN OLD POOR-LAW MEDICAL AGREEMENT.

To the Editor of THE LANCET.

SIR,—Perhaps the following extract from the meetings of the Vestry of West Coker, Somerset, giving the terms of agreement for the "parish doctor," may be of sufficient antiquarian interest as to merit insertion in your columns. It is the earliest notice of the kind that I have seen. Like the present arrangements with the Local Government Board, it will be seen that midwifery and compound fractures are "extras."

I am, Sir, yours faithfully,

West Coker, Somerset, April 27th, 1885. JNO. EADIE.

"1778, May 18th.—At a vestry legally held it was agreed on the part of the parishioners to advance yearly the sum of five guineas to Mr. Shorland of Yeovil for the following purpose: that is to say, that he, the said Mr. Shorland, shall give due and necessary attendance on the poor of this parish when required, and lend them when needful his good assistance as a surgeon and apothecary, compound fractures and midwifery excepted in the first and small-pox in the latter; and Mr. Shorland on his part doth promise faithfully to fulfil the above when required."

(Here follow the signatures.)

Another extract:—

"24th April, 1786.—This agreement then ceased."

"AGORAPHOBIA."

To the Editor of THE LANCET.

SIR,—In reply to Dr. Evans's question in your last issue concerning the treatment of agoraphobia, allow me to refer him to my letter on this symptom in THE LANCET of Jan. 17th last. The best prescription for this disagreeable state of things is a mixture of bromide of potassium with sal volatile. Walking at night is, I find, in these cases much less dreaded than walking in the glare of the day; and by degrees the muscles of the limbs become firmer and more developed, and a general healthy tone takes the place of the former miserable condition of nervousness.

I am, Sir, yours faithfully,

Richmond-terrace, S.W., April 27th, 1885. H. SUTHERLAND.

To the Editor of THE LANCET.

SIR,—In answer to Dr. Evans, I may say that I have found the above condition to be a very frequent, and sometimes the only, symptom of a neurasthenic state characterised by loss of vaso-motor tone and an increased quantity of urea in the water passed by the patient. I have had a considerable number of such cases lately under my care, and, with one or two exceptions, have found that the patients have completely recovered their health in periods varying from a week to a month under the internal administration of three grains of valerianate of soda three times a day, and systematic vibration of the peripheral nerves with the electro-percuteur. I shall be happy to give Dr. Evans any further information he may desire upon the subject.—Yours truly.

Moorgate-st., E.C., April 27th, 1885. GEO. HERSCHELL, M.D.Lond.

"THE PRIMROSE."

THE first number of an amateur monthly magazine christened *The Primrose*, and published on April 19th in honour and commemoration of the late Lord Beaconsfield, has recently appeared. We understand that the magazine is intended for private circulation, and with a view of adding to the funds of the National Aid Society for the care of the sick and wounded in the Soudan. The first number contains many little stories and fragments of an amusing kind. Copies of the magazine may be ordered of A. Wilson Fox, Esq., 67, Grosvenor-street, or of C. L. Sclater Booth, Esq., 74, St. George's-square, London, S.W.

Dr. Golaub Sing is referred to some remarks which appear on another page.

REAL DISEASE OR MALINGERING?

To the Editor of THE LANCET.

SIR,—About a fortnight ago I was asked by a patient to examine a servant in his employment. She was nineteen years of age, and was described as a steady, industrious girl. She complained of palpitation of the heart, with periodical attacks of syncope. I elicited that she had had rheumatic fever, and was subject to irregular and excessive menstruation. But the symptom which caused her employers the greatest uneasiness was the markedly cyanotic appearance of her lips whenever she was seized with one of these attacks. When I saw her, her lips were of a normal colour. Her pulse was slightly irregular in rhythm, but more so in volume. On examination, I detected a very slight mitral systolic murmur. Her lungs were sound. I noticed no embarrassment in her breathing, nor was there any anasarca; the urine was found to be free from albumen. I communicated my diagnosis to the girl's master and mistress, and expressed my ignorance as to the cause of the cyanosis, telling them that, in my opinion, the lesion of the heart had not produced sufficient disturbance in the pulmonary circulation to produce such an advanced symptom. Four days ago I was summoned to see the girl, as she was very much worse. I found her in bed; her face was very pale, and her lips were of a cobalt blue. Examination revealed that the inside of the lips was of the natural colour. With the aid of a moistened towel I proceeded to restore the natural colour to the outside of the lips, and transferred the cyanosis from the lips to the towel, on which I discovered traces of previous attacks of cyanosis. I then informed her employers that it was a case of "fiction founded on fact," and that the girl, through hysteria or for the purpose of malingering, had had recourse to Nature to supply a symptom of which she deemed herself deficient. This they cannot, and will not, believe, remarking that the girl has never sought to profit by her cyanosis, and that a careful examination of her effects had failed to discover the wherewithal for the fraud. The girl, who is very intelligent, has, to me and to her employers, strenuously and in the most indignant manner denied the truth of my statement.

I would esteem it a great favour if in your next issue you would inform me whether my opinion is capable of error in this case, and whether there is really any morbid state capable of producing a cyanosis susceptible of cure by soap and water. You would thus satisfy me, and I would be enabled to satisfy my patients.

I am, Sir, yours faithfully,

FREDK. W. FRIEND,

Hon. Surgeon, Isle of Man General Hospital.

Douglas, Isle of Man, April 20th, 1885.

CONTAGIOUS DISEASE CARDS.

To the Editor of THE LANCET.

SIR,—At page 677 of THE LANCET of April 11th there is a paragraph stating that Mr. Adams "has devised a card" which "embodies a neatly-drawn-up chart, and indicates the presumed normal periods of latency, premonitory fever, duration of pyrexia, and of infectiveness" of certain contagious diseases. "It is issued by Messrs. Churchill." I think it is only right that attention should be called to the fact that the figures given by Mr. Adams were previously published in the *Health Journal* of March, 1884, accompanied by a coloured chart, and that the figures and chart were shortly afterwards republished in a pamphlet issued by Mr. Heywood at 6*d*.

I am, Sir, your obedient servant,

Chester, April 18th, 1885. G. A. KENYON.

⁂ We think it only due to Mr. Francis Vacher, the author of the pamphlet referred to by our correspondent, to insert the above. So far as the chart and tables go, the similarity between the two is absolute; and it is to be regretted that Mr. M. A. Adams has not acknowledged the source from which he apparently derived not merely the idea, but the actual figures of his "card." Mr. Vacher's pamphlet contains the evidence upon which these figures are based, and is well worthy of perusal.—ED. L.

"IS ALCOHOL A FOOD?"

To the Editor of THE LANCET.

SIR,—In my paper on the above subject, which you were kind enough to publish last week, I notice a printer's error, which I trust you will allow me to correct. In page 744, twenty-third line from the bottom of the first column, instead of "sulphate or oxide of chromium" read "sulphate *of* oxide of chromium.—I am, Sir, yours truly,

Potter's Bar April 27th, 1885. T. W. THOMPSON.

SPURIOUS CUBEBS.

To the Editor of THE LANCET.

SIR,—A few days ago a patient of mine who had been taking cubeb powder called on me, complaining of its having made him feverish, with sickness and purging. He looked wretchedly ill and weak; the pulse was feeble, the tongue very much coated, and he had general aching pains all over. He told me that he had taken the powder for a week without its disagreeing with him; then he had to buy some more. The new sample had a more acrid and unpleasant taste, and gave rise to nausea, followed by diarrhœa, &c. He persevered with it for three days, when he became so ill that he could not go to business. He attributed his present condition entirely to the new cubebs, which he brought for me to see. On comparing it with a sample procured at Messrs. Corbyn's, I found that it was lighter in colour, and that on crushing some of it on a sheet of white paper lighter streaks were seen amongst the general brown. The smell was drier, less aromatic, and the taste hotter, more peppery, with less of the aromatic cooling pungency of pure cubebs. It appeared certain that this sample was adulterated with some powder possessing acrid and irritant properties. On inquiring amongst the wholesale houses, I found that a spurious berry had lately been offered for sale under the name of cubebs, and that a certain quantity had been sold; and I feel sure, on comparing the berry with the adulterated powder, that it was mixed with it. I understand that these spurious cubeb berries were offered for sale in the French markets, but were seized by the authorities. The berry somewhat resembles cubebs in its external character, being wrinkled and stalked, but it contains a single hard seed; it is not a pepper, but is the berry of a species of laurel from West Africa. I may add that my patient soon recovered, and is now taking cubeb powder without any bad effect, so that it is clear his recent indisposition was caused by the adulterated sample.

The consideration of this gross example of adulteration shows how impossible it is for us to depend upon the present system of Government inspection, for the bags of spurious cubebs were publicly offered for sale without any hindrance from the authorities, although Mr. Holmes called attention to them in the *Pharmaceutical Journal*. The subject is one of great importance, and I hope that we may look forward to some more perfect means for preventing the wholesale adulteration of drugs than at present exists; for surely it is as important to have the supplies at the drug brokers inspected as it is to test a few drops at the retail chemist's.

I am, Sir, yours faithfully,

Frederick-place, Old Jewry, April 27th, 1885. BUXTON SHILLITOE.

Mr. F. P. Smith (Shepton Mallet).—The firm in question has acted in accordance with the practice of high-class publishers.

"TRANSVERSE HERMAPHRODITISM."

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 25th Mr. J. H. Morgan is reported to have said, in the discussion on a case of Hypospadias at the Pathological Society, that he was uncertain whether the mixture of external and internal organs of different sexes in the same individual had ever been observed. In the last bulletin of the Anatomical Society of Paris will be found the report on such a case. The specimen is in the Museum at Paris. It was that of a full-grown fœtus which died during protracted delivery, and which I dissected, fully believing that it was a male. The penis was well formed but for slight hypospadias, and the scrotal raphé was very marked. The bulb and prostate were extremely well developed, and into the latter opened a vagina, above which were a perfect uterus, ovaries, Fallopian tubes, &c. The other viscera were normal. So far as I have been able to ascertain, this is the first dissected specimen in this country; but cases have been recorded in France in which such a strange condition (well expressed by the term "transverse hermaphroditism") must have existed. Thus M. Petit was consulted by a married man who was sterile, and who had a flow of blood from the urethra every month; so that it is plain that if my case had attained adult life he would have presented no external appearances hindering him from being married. There is no note as to the state of the mammæ in M. Petit's case, but they could not have been large. See also M. Bouillaud (*Journal Hebdomadaire de Médecine*, tome x., p. 406). Transverse hermaphroditism as a rare cause both of sterility and of hæmaturia is worth being kept in mind.—I am, Sir, yours truly,

Cavendish-square, April 27th, 1885. J. HUTCHINSON, Junr.

Mr. G. Heaton.—In 1883 the births of males in England and Wales were 103·5 to 100 of females. The numbers for the United Kingdom are not yet available.

Zero.—We are not aware that anything has been done in the matter to which our correspondent refers.

"CORONERS AND POST-MORTEM EXAMINATIONS IN WORKHOUSES."

To the Editor of THE LANCET.

SIR,—Your Liverpool correspondent, under the above heading, calls attention to the "Croydon Workhouse case" in your issue of April 25th. In all the published reports of the case which I have read, and I think I have perused nearly all of them, the judge was careful to use the word "workhouse infirmary," and not simply "workhouse"—a distinction which carries a great difference.

I am, Sir, yours faithfully,

April 27th, 1885. A MEDICAL OFFICER.

RINGWORM.

To the Editor of THE LANCET.

SIR,—All of us will agree with Mr. Alder Smith when he asserts, in speaking of tinea capitis, that he "considers it extremely difficult to certify that a child who has had ringworm is absolutely well" (THE LANCET, January, 1880); but one rarely has the same experience in mild cases of the disease attacking other parts of the skin. In fact, if no spores are to be found in the epidermis scraped off the spot at the end of two weeks after treatment has been discontinued, it has always been, under ordinary circumstances, in my experience, safe to permit the child to mingle with its companions, and resume school work. That this, however, is not invariably a course free from risk the following case has lately shown me. A little boy, on Feb. 17th last, was observed to have a red spot on the outer side of the right eye. As it increased in size, he was sent to me on the 19th, when it had reached the size of a sixpence; the margin was slightly papular and red, and the centre was much paler and somewhat scaly. The epidermis scraped off and soaked in liquor potassæ showed under the microscope plenty of ringworm spores. After a few days' treatment no spores could be seen. The treatment was discontinued on March 1st. On the 5th there were no spores, the spot appearing almost natural; and a week later the same condition was noted. The child resumed the companionship of his brothers, but had separate toilet arrangements and bed. On April 17th he came again to me. On the outer edge of the old spot a small red papule was seen, and under the microscope a few conidia were found in the epidermis scraped from it. In fact, the ringworm had recurred after five or six weeks of apparent absence on the face of a thin-skinned child, who had not another spot on him, and who had not been exposed to any fresh infection that could be discovered. I may remark that there is much fine downy hair all over the skin, such as is not uncommon in a certain type of children, and the germ that revived probably found a safe hiding-place deep in some of the hair follicles.

The above case has only been narrated with the object of eliciting the observations and experience of others as to the interval after which it is safe to allow a child who has had mild ringworm (not affecting the scalp) to return to school and family life. The fortnight, which I have always considered enough after treatment has been left off and the case apparently cured, appears to be, at all events in some cases, insufficient.

I am, Sir, yours faithfully,

East Twickenham, April 23rd, 1885. H. HOWARD MURPHY, M.D.

"DISINFECTING CHAMBERS."

To the Editor of THE LANCET.

SIR,—Permit me to inform "A Medical Officer of Health," in answer to his question under the above heading in your issue of April 18th, that I think he will find Dr. Scott's disinfecting apparatus a most efficient one. It is made by Maguire and Son, of Dawson-street, Dublin, who have been awarded prizes and diplomas of merit for it at various exhibitions where it has been shown. In Dublin it is used at the Cork-street Fever Hospital and at the Rotunda Lying-in Hospital, and gives satisfaction. I believe it has been supplied to several union districts and townships both in England and Ireland, as well as to the War Department for use in military hospitals. One of the chambers is, I know, at the Herbert Hospital, Woolwich, and there is another at Blackpool. By means either of gas or of a coal and coke furnace a temperature of 300° F. can readily be obtained and maintained in them as long as requisite.

I am, Sir, yours truly,

GEORGE F. DUFFEY, M.D. Dub.,
Vice-President, King and Queen's College of Physicians,
Dublin, April 24th, 1885. Ireland.

To the Editor of THE LANCET.

SIR,—In reply to "A Medical Officer of Health," I would beg to draw his attention to Dr. Scott's Patent Self-regulating Gas or Coal Disinfecting Chambers, awarded a gold medal in Dublin, and several special prizes at London and other exhibitions. Several improvements have been recently added, partly on the suggestions of the authorities most interested, and partly from actual experience. An arrangement is made whereby the heated air is caused to circulate within the chamber to maintain even temperature throughout. An appliance is also added by which hot air is forced into the interior of mattresses and feather beds. The various improvements render Dr. Scott's invention the best, the safest, the easiest worked, and the most economical in fuel. The regulator turns down the gas when the desired temperature is reached, and no gas is wasted. A very large number have been supplied to Government and other institutions.

I am, Sir, yours truly,

Dublin, April 22nd, 1885. WM. ROBT. MAGUIRE, F.R.M.S.

Mr. T. H. Buckler (Biarritz).—We have nothing to add to our remarks published in THE LANCET, vol. ii., 1882, page 851.

"AUTUMNAL STONE."

To the Editor of THE LANCET.

SIR,—Could any of your readers give me any information about the "autumnal stone"? It is like a piece of white marble. Does it possess any medical properties? It is kept in cotton wool in a stoppered bottle, and has on the bottle the words "Wuhu No.," with some Chinese writing on. It was given to me by a friend, and came from abroad.

I am, Sir, yours respectfully,

Conway, April 23rd, 1885. ROBERT JONES, Surgeon.

Dr. Sargent (Shadwell).—Although the unregistered practitioner referred to by our correspondent has no legal right to use the official form of medical certificate issued by the Registrar-General "for the use of registered practitioners only," we fear that there is no legal penalty incurred by such misuse of the document, since the unregistered practitioner is careful to guard against any pretence of being registered, which would be a punishable offence. Forms are only issued to persons *supposed to be registered practitioners. A certificate signed in such a* manner as the one *enclosed by our correspondent would not be* accepted as a legal certificate by the local registrar, and the cause of death would be entered in the death register as uncertified.

Mr. E. Shoesmith (Rochdale).—So far as we know, data are wanting to show whether injurious results follow the constant use of salicylic acid as a preservative of animal food.

A. B. has not enclosed his card.

AFTER-CARE OF MENTAL CONVALESCENTS.

To the Editor of THE LANCET.

SIR,—The Ladies' Committee of the Association for the After-care of Poor and Friendless Female Convalescents on Leaving Asylums for the Insane propose holding a bazaar at the Town-hall, Kensington, on Tuesday, May 19th, and the following day, in order to raise funds towards the *opening of a Home for Mental Convalescents. Contributions* may be forwarded to Mrs. Ellis Cameron, 27, Church-street, Kensington, or to me. I am, Sir, yours obediently,

HENRY HAWKINS, Hon. Sec.

Chaplain's House, Colney Hatch, N., April 27th, 1885.

*** This is an excellent charity, and deserves sympathy and practical help.—ED. L.

CASCARA SAGRADA.

To the Editor of THE LANCET.

SIR,—Perhaps some of your readers can inform me whether cascara sagrada possesses two principles, one an hepatic and the other an intestinal stimulant, so that the difference in the action of the two preparations might be explained by the removal during manufacture of one or other of them, or their presence in different proportions in the crude drug. I am, Sir, yours truly,

Glan Menai, Llandudno, April 28th, 1885. T. L. K. DAVIES, M.B.

Late Assistant.—The original letter cannot now be recovered. If our correspondent will repeat his inquiry and append his name, we will endeavour to answer his question.

A M.O.—We cannot decide the question.

Inquirens.—The spirituous tincture should be used.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Buxton Shillitoe, London; Dr. C. E. Saunders, London; Dr. De Watteville, London; Mr. Reginald Harrison, Liverpool; Dr. Luke Armstrong, Newcastle-on-Tyne; Dr. Thin, London; Mr. A. T. Bentley, Manchester; Mr. A. Field, Bradford; Dr. Shirtliff; Dr. Cartwright Reed, Douglas, Griqualand; Dr. Musser, Philadelphia; Dr. Althaus, London; Dr. H. Sutherland, London; Dr. Massy; Dr. Illingworth; Dr. Edge, Salford; Mr. Harvey, London; Mr. Jackson, Somerby; Mr. W. M. Maguire, Dublin; Mr. Pilkington; Dr. H. M. Murphy, Twickenham; Mr. Wm. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready *means of finding any notice, but is in itself an additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

L DEPARTMENT

The Annual Oration

DELIVERED ON MAY 4 AT THE

MEDICAL SOCIETY OF LONDON

ON

OLD AGE AND THE CHANGES INCIDENTAL TO IT.

By G. M. HUMPHRY, M.D., F.R.S.,

PROFESSOR OF SURGERY AT THE UNIVERSITY OF CAMBRIDGE.

MR. PRESIDENT AND GENTLEMEN,—Old age acquires a gradually increasing interest as advancing civilisation enables a larger number of persons to attain to it, and affords them additional means of enjoying it and profiting by it. From the schoolboy day, now full fifty years ago, when the "De Senectute" of the great Roman orator made a lasting impression upon me, the subject of old age has had some fascination for me, though multifarious avocations have prevented my giving much attention to it. In the past year the Collective Investigation Committee of the British Medical Association, at my instance, commenced an inquiry respecting aged persons, and issued a form, with a memorandum, for the purpose of collecting information of various kinds respecting the condition, habits, &c., past and present, of persons who had attained to advanced age. The minimum age for the subjects of inquiry was fixed at eighty. We are indebted to many members of the profession, and to some others, for the returns they have taken the trouble to make, which at the present exceed 500, the number of males and of females being nearly equal. These have been, in part, carefully tabulated and analysed by myself, with the aid of my friend and assistant, Mr. A. Francis. It is not to be supposed that from this, or other investigations of the like kind, any very startling results will be obtained; for the hill of knowledge is mounted with slow and laborious steps, and we must be content to advance little by little. Moreover, I do not propose to weary you with many of the details of this inquiry, which, I may observe, is not yet completed, but to make a few remarks upon the subject of old age, which will be to some extent based upon information derived from the inquiry just mentioned.

We are, I think, too much accustomed in our ideas to limit the work of development to the periods of adolescence and maturity; and, indeed, the surpassing wonders of that work—I say surpassing wonders, for unquestionably the processes of development of an animal body are the most marvellous, the most mysterious, and the most interesting in the whole range of the physical world—are most fully demonstrated in the early periods of life. But they do not end in them, or even when the body has been brought to its fully matured condition. They continue in a definite and orderly manner, though with lessened and lessening activity, to the termination of life, at whatever period that termination may occur. The march of changing events in the human body, from the age of forty or fifty to one hundred, is as regular, as orderly, as developmental, though less quick, and therefore less apparent, as it is from birth to adolescence, or from conception to birth. It is one of the resultants of that inscrutable *vis*, call it what you will, and refer it to what you will, which makes all nature one, which determines the course and end of each animate and inanimate object, and by which, in the well-known words of Keble,

> "To its funeral pile this aged world is borne."

A main feature of the "ascending," if we may so call it, development, the development from birth to maturity, is an increase of material, an increase of activity, and an increase of strength—of passive or resisting, as well as of active, strength; and the main feature of the "descending" development, the development from maturity onwards, is a lessening of material, a lessening of activity, and a lessening of strength. In the normal "ascending" development, material and strength are added to the several parts of the body in due relation to their respective requirements, so that they may all grow on *pari passu*, and the proper harmony of proportion may be maintained between them; and in the normal "descending" development, the relative proportions of the several structures and organs are preserved, while weight, force, and activity are being lowered by gradual and well-adjusted diminution of material and of nutritive activity. During the time that the bones are becoming lighter and less capable of offering resistance, the muscles become, in like proportion, lighter and weaker, and with a narrowing range of action; and the associated volitional and other nerve-apparatus exhibits a corresponding lowering of energy and force. The loss of will to run, jump, and indulge in athletic sports is, or should be, commensurate with the inability of the muscles to effect the requisite movements, and of the bones to bear the requisite shocks. There should not even be a sigh for what is gone, or a longing for its return, though great, perhaps greater than ever, may be the pleasure in beholding the perfection of bodily form and in witnessing the manifestations of strength and activity in the supple frames of the young. The weakening of the heart and the diminished elasticity of the arteries provide a proportionately feebler blood-current; and a lower digestive power and a lessened appetite provide a smaller supply of fuel to feed, not enough to choke, the slowing fires. Thus the capacity for action is diminishing, and the demand for it and the material for it are diminishing also; and all are diminishing in due ratio to one another. It may be said, indeed, that at all periods of life the healthy and well working, and especially the enduring, quality of the body, depends upon a good adjustment, a good balance, of the several parts; and it is upon the well-ordered, proportionately or developmentally regulated, decline in the several organs that the stages which succeed to maturity are safely passed, and that crown of physical glory, a healthy old age, is attained.

A time comes at length when, in the course of the descending developmental processes, the several components of the machine, slowly and much, though equally, weakened, fail to answer to one another's call, which is also weakened, when the nervous, the circulatory, and the respiratory organs have not force enough to keep one another going; then the wheels stop rather than are stopped, and a developmental or physiological death terminates the developmental or physiological decay. The old man who had gone to bed apparently much as usual is found dead in the morning, as though life's engine had been unable to repair itself in sleep sufficiently to bear the withdrawal of the stimulus of wakefulness. Or some exertion may be followed by too great exhaustion. Dr. Willis, the attendant upon King George III., at the age of ninety, after a walk of four miles to see a friend, sat down in his chair and went to sleep, or was thought to be asleep, but he did not wake again. Or some slight, unusual, scarcely noticed excitement may have the same result. A cattle-dealer, aged ninety-eight, who attended Norwich Cattle Market on a Saturday in December of last year, soon after talking and laughing somewhat heartily with a few friends on the following Tuesday was found to be dead. Or a slight indisposition, further lowering the status and force of some organ, fatally disturbs the feebly maintained equilibrium. A lady, aged ninety-four, attended the early service at church, to which she walked a distance of a quarter of a mile to and fro, caught a slight cold, and died in the night.

How much may those who pass gently into this natural or physiological death be envied by the many sufferers under the protracted and painful pathological processes which too often induce a premature extinction of life! The most distressing part of medical duty is the being called upon to witness, with the inability to arrest, the onward course of disease, such, for instance, as that of a slowly but surely growing cancer, boring its way into the strong and sturdily resisting frame: and the great hope and aim of medical study is to prevent such fatal interferences with the developmental processes, and to enable these processes to work out, in their own uninterrupted way, the quiet, easy, gradual method of dissolution.

Yet, strange and paradoxical as it may seem, this gradual natural decay and death, with the physiological processes which bring them about, do not appear to present themselves in the ordinary economy of Nature, but to be dependent upon the sheltering influences of civilisation for the opportunity to manifest themselves and to continue their work. For the needs of the first, or infantile, period of helplessness Nature has made a sufficient provision in the parental instinct which protects and nurtures the young. But this lasts only so long as the requirement for it exists. It ceases as soon as the young has the ability to help itself; and it does not return and is not supplemented by anything of its kind. It gives way before that struggle for existence which is the engenderer of selfishness, dominating over all other impulses and shutting out all heed for the worn and weary, for the feeble and the decaying. These, being unable to help themselves, are crushed out by the various provisions which Nature makes for their destruction. The good result of this great seeming evil being that all in the natural, or, primitive, animal world is in the ascendant to, or in the enjoyment of, bodily perfection. All teems with budding life or full health and strength. To falter is to fall; forasmuch as the *first evidences of weakness and the beginning* of decay arrest themselves by preventing the power of self-maintenance in the weak and the decaying.

The same with disease. It, in like manner, stops itself. Indeed, it can scarcely be said to be allowed to enter into the pure realm of Nature. Sick animals are not there provided for, have no abiding-place there, and soon perish; so that there is no wasting and pining, no lingering fevers, no destroying cancers, no decrepit frames. Neither the bird that fails to elude the hawk nor the hawk that fails to seize the bird can long continue in existence. Each animal has its so-called enemy ready and at watch to deliver it from feebleness and disease; and the sudden destruction which *awaits them all, without fearful premonition and with little* pain—this killing in lieu of death—instead of being, as it is sometimes regarded, a cruel feature in Nature's plan, is a happy provision for deliverance from the slower death which increasing failure or progressing disease would have involved.

Thus, in the economy of Nature, death is swift, and comes early, as soon, at least, as failure of strength renders the animal unable to protect, or provide for, itself; and man, it would seem probable, had no exemption from this sharp, though, on the whole, beneficent law of animal life. In early times, when the race was to the physically strongest, when health, and strength, and activity were necessary to provide the *hand-to-mouth means of sustenance, and to give* defence, when men and animals were much on a par in this and many other respects, early death must have been the common fate, being brought about by climacteric agencies or by the tooth of the hungry beast, or by the hand of man himself. This, indeed, we still find to be the case among some of the rude races of mankind. But in man was the germ of a better order of things, the germ of sympathy with, of feeling and love for, others, which was besides and above the mere parental instinct, and which was calculated to counteract and over-ride the selfish bent, and to raise man in this, as in some other respects, above the mere animal. This has already done much, *and it has still an ample field for future development.* Through the growth of this germ it was given to man to introduce a new factor into the economy of Nature, and, by forethought, by mutual co-operation, and by care for others, which are the very essence, at any rate the very best feature, of civilisation, to prolong life, when by this very forethought and sympathy life had become more valuable, and when the prolongation of it had, consequently, become more desirable; and scope was thus afforded for the carrying out of those descending or senile developmental processes which must have been nearly dormant in the earlier periods of human existence.

It was not to be expected that this good seed should be without a blending with tares, and the scope thus given for the fuller development of the physiological processes gave scope also for the development of the pathological processes, and enabled the various diseases to spring up and take their course, afflicting not man only, but those animals also which come under his fostering or protecting influence. It may therefore be said that the prolongation of life into and through the periods of decay, and into and through the processes of disease—indeed, almost, if not quite, the very existence of decay and disease—is the result of human forethought and sympathy. In other words, decay and disease are, by civilisation, substituted for quick and early death. Without attempting to balance the *pros* and *cons* of this, we know it to be a position from which there is not, and ought not to be, any disposition to recede; and if there were the wish, there is not the possibility. The onward march of civilisation is a necessity, and the onward progress of disease will tend to go with it. But it does remain for forethought and sympathy to narrow the range of the evils they have themselves engendered, or which have sprung up with them; and it is pre-eminently the noble work of our profession to contribute to this—to weed out and check the growth of the morbid tares, and to help the good seed to grow on to its full harvest,—to prevent, that is, the origin, and to arrest the advance, of disease, and to give to the body the best opportunities for health and longevity. In this great physical work, let it be remembered, we shall not to any great extent succeed, unless our efforts are accompanied by equal efforts to carry out the higher and more important work of removing those impurities in the moral atmosphere for which civilisation has so much to answer, and with which the sources and spread of disease are closely—more *closely, perhaps, than we think—associated.*

The first requisite for longevity must clearly be an inherent or inborn quality of endurance, of steady persistent nutritive force, which includes reparative force and resistance to disturbing agencies, and a good proportion or balance between the several organs. Each organ must be sound in itself, and its strength must have a due relation to the strength of the other organs. If the heart and the digestive system be disproportionately strong, they will overload and oppress the other organs, one of which will soon give way; and as the strength of the human body, like that of a chain, is to be measured by its weakest link, one disproportionately feeble organ endangers or destroys the whole. *The second requisite is freedom from exposure to* the various casualties, indiscretions, and other causes of disease to which illness and early death are so much due. Now, in both these—notably, in the second—woman has the advantage over man, and she consequently attains to greater age. In the report of the Registrar-General for 1873, eighty-nine persons were returned as dying at or over the age of 100. Of these, ten only were males; and the superiority of female life is well known by insurance offices to exist, notwithstanding the higher rate of mortality that has been observed during the child-bearing period, and which, there is reason to think, is now slowly disappearing. That this superiority is not entirely due to the comparative *freedom from exposures* and to the greater temperance in the woman, but is partly a result of a stronger or more enduring inherent vitality, is shown by the fact that, even in the first year of life, when the conditions and exposures of male and female infants are the same, the mortality of girls is less than that of boys. A somewhat larger number of boys are born, but they are more difficult to rear; so that the females soon gain the numerical lead, and maintain it, with almost steadily increasing ratio, to the end. This superiority may be to some extent associated with the less wear and tear in the smaller machinery of the woman's frame as compared with that of man; and one might expect that the small persons in both sexes would live longer than those of greater stature. This, however, scarcely seems to be the case. We find from our returns that the average height of the woman above eighty is about 5 ft. 3 in., which, allowing an inch for the shortening incidental to age, makes it to fall little, if at all, short of the average middle-age stature. The men also we find to be 5 ft. 6 in., which, making a corresponding allowance, gives them a good average height. It may also be observed, which we should not have expected, that the rate both of the pulse and respiration is quicker in the longer-lived sex; the average pulse in the women over eighty being 78 to 79, while that in the men is 73; and the respiration in the women is 22, while that in the men is 18 to 19.

It is a point of interest, in connexion with the inborn or hereditary quality, that phthisis is reported to have appeared in some of the immediate relatives—father, mother, brothers, or sisters—of 82 of the 500 aged persons; in 51 of the relations of the 250 females, and in 31 of those of the 250 males. In the reports of some of these, it is stated to have occurred in several members of the family; and, in a few instances, the disease was manifested in both father and mother. It is evident, therefore, that the delicacy, or peculiarity, whatever it be, of constitution, which is associated with the tendency to the development of tubercle, is not only not *incompatible* with longevity, but is not unfrequently associated with it. No other special peculiarities have been shown in sufficient numbers to deserve notice here. The greater proportion are reported to be of long-lived families, to have enjoyed good health throughout their lives, to have had good appetite and good digestion, requiring little or no medicine, to have been moderate or small eaters, to have taken little alcohol, and, commonly, not much meat; they have been good sleepers; and they show no traces of gouty or rheumatic affection in the joints of the hands.

I have said that the main features in the downward, or senile, developmental process are a diminution of material and a diminution of force; and I apprehend that in the normal state it should be simply this—such a diminution, with, perhaps, a slight addition to the amount of oily matter naturally existing in the tissues; and that the other changes and degenerations that are incidental to age are no part of, but are rather to be regarded as deviations from, or morbid departures from, the natural phenomena. Let us consider the changes which take place in the skeleton, forasmuch as they are most appreciable, and, in many respects, the most interesting. The bones which, up to maturity, had been gaining in weight and size, now gradually lose weight, but do not ordinarily diminish in size, as they do in atrophy, from paralysis; indeed, they not unfrequently rather increase in size from the continuance of a slow process of subperiosteal ossification. To this, in part, may be attributed the sharp outlines which the figure of old persons commonly acquires, except in the case of those who become corpulent. The absorption takes place first and chiefly in the more vascular and cancellous parts, the bony plates becoming thinned and removed, and the cancelli and the canals being enlarged and filled with marrow, while the bony tissue itself becomes often, though not always, more impregnated with oily matter. Hence, although the walls of the shaft are being gradually thinned from within, the ends of the bones are first and most affected, which explains the greater liability to fractures near the joints in old persons than in the middle-aged. This change, with the proportionate liability to fracture, is especially remarkable in the trochanteric and cervical parts of the thigh-bones, the strength of which is so much dependent upon the strength and disposition of the cancellous plates.

This change takes place earlier in women than in men, which may be a consequence of the earlier cessation of active occupation in them, and the less amount of out-door exercise they usually take, or it may be due to some natural predisposition in them, associated with a greater tendency to adipose degeneration in other parts, and evincing itself occasionally in an exaggerated manner in the production of osteomalacia. The greater frequency of fracture of the neck of the thigh-bone in them is to be attributed to the greater weakening which the part thus undergoes, as well as to the more near approach to a right angle which the neck naturally forms with the shaft in women than in men.

The vascular and cancellous character of the alveolary processes of the maxillary bones renders these parts peculiarly liable to undergo wasting or absorption, causing the loosening and falling out of the teeth. This takes place earlier in women than in men; the average number of teeth, according to our returns, in men above eighty being 6 and in women 3. Of 221 males, 57 are reported to be edentulous, and of 234 females, 113 are said to be in that condition. The process of absorption and loosening of the teeth also bears a relation to the sponginess of the alveolary processes, being greatest in the upper jaw, in which the teeth in 455 of our octogenarians, in whom an account of the teeth is given, are 736, those in the lower jaw amounting to 975. For the same reason they are greater in the molar and premolar regions than in the incisor and canine, the numbers of teeth remaining being 559 molars and premolars, 409 canine, and 743 incisors.

This absorption of the alveolary processes and consequent removal of a part of the bodily machine which is in full and daily use is remarkable, though it has something of a parallel in the removal of another cuticular appendage—namely, the hair of the head. For the reasons I have given it can scarcely take place in the condition of struggle for existence of the natural animal world, or in man in his primitive state; and it is accordingly commonly observed that the unearthed skulls of our early ancestors are well provided with teeth. The loss of teeth would imply a decay which the early man could scarcely have survived. What effect in more modern life this loss has upon the general health and the duration of the body is not easy to determine. It is often survived for many years; and it may be noted that, as before stated, it takes place more in women than in men, though they are the longer lived. Civilisation is doing something to supply the deficiency which it thus brings in its train by providing artificial substitutes; and they are at any rate free from some of the disadvantages, such as disease and decay, associated with the natural organs.

It is remarkable how completely the alveolary processes become cleared away, so that scarcely a trace of them remains above or below; and the whole framework of the face, which ministered with them to mastication, is attenuated, and the body of the lower jaw is reduced to the narrow bar of its hard lower margin. At the same time, the resistance of the teeth being removed, the direction of the pull of the muscles upon the jaw is altered so as to open out the angle of the bone and bring the ramus and the body almost into a horizontal line. Thus the form of the lower jaw returns nearly to that of the infant. But there is this great difference, that whereas in the infant the bone consists mainly of the tooth-bearing or alveolary part, and the sub-alveolary portion scarcely exists, in the senile condition the latter only remains, the former having been cleared away.

A similar alteration of form in a bone, from an alteration in the direction of muscular force, or from pressure by other cause, may, as we know, be produced in any part of the skeleton, and at any time of life; and a very analogous change to this in the lower jaw may be observed to take place in the neck of a thigh-bone after amputation in the thigh; for the nearly horizontal pull of the muscles upon the trochanter, not being resisted by the vertical weight of the body upon the head and shaft of the bone, will have the effect of widening or opening out the angle. Some years ago I placed in the Pathological Museum at Cambridge two specimens illustrating this; and the fact is not without its interest in connexion with the often-debated question whether the converse of this change takes place in old age—that is, whether the angle between the neck and the shaft of the thigh-bone becomes lessened. A change of the kind certainly takes place in the ascending period of life, the angle being widest in infancy and lessening during growth; and this change is more marked in females than in males, the difference in the angle of the thigh-bone between the two sexes taking place, in all probability, about the time of puberty, when the pelvis is widening in the female and the hips are becoming more prominent. But does this alteration continue in the descending period? I have taken some pains to ascertain this, and have made several measurements of the angle at the junction of the neck with the shaft of the thigh-bone in old people; and though I have in some instances found it less than in the adult, in the greater number of cases it was not so. I have not had the opportunity of making sufficient measurements to settle the question, but, so far as my observation goes, the change is the exception rather than the rule; and I am not aware that a change of the kind takes place in any other bone as a mere consequence of senility—without, that is to say, there being some alteration in the direction of the pressure or forces exerted upon the bone. In the bent back of old age the vertebræ become modified in form; but this is a consequence of the stoop, from enfeebled action of the dorsal muscles, throwing the weight of the trunk too much upon the fore part of the spinal column.

The changes which take place in the skull during old age are interesting. Commonly they correspond with those in the facial part, and the whole cranium becomes lighter and thinner, and therefore smaller. In some cases, however, it acquires an increase of thickness, by deposit of bone on the interior of the brain-case, and chiefly of the calvarial part, which seems to depend upon the lessened pressure there, and the consequent greater afflux of blood caused by the shrinking of the brain. The increase is usually most marked in the frontal region, which accords with the fact that the shrinking is most pronounced in the frontal lobes of the brain. In not a few instances I have found, as mentioned in my treatise on the skeleton, that there has also been an increase in the density and weight of the brain-case to such an extent that, in spite of the loss of the teeth and of the alveolary processes of the jaws, and the atrophy of the face, the weight of the entire skull exceeded that of the average adult skull. In a woman reputed to be 103, whom I examined, the contrast between the thick, dense, heavy skull, and the extremely attenuated light thigh-bone, both of which are in the Cambridge Museum of Anatomy, is very striking. In connexion with this change and the cause to which it is referred, it may be observed that other parts of the osseous system, particularly the harder parts, are liable to undergo similar changes, leading to enlarged and sclerotic conditions, when at any period of life and from any cause they are subject to an increase of blood-supply.

The cartilaginous parts of the skeleton become somewhat thinner, which accounts for the loss of height in the aged; but I do not think that they usually undergo any other perceptible change in ordinary healthy old age. I have invariably found the costal cartilages soft in old people in whom I have had an opportunity of making an examination after death; the body of Old Parr, as described by Harvey, therefore presenting in this respect, as I believe, no exception to the general rule. And I regard the calcification of them to be a morbid rather than a senile change—a degenerative change to which the body is liable, as it is to cataract, bronchitis, and some other conditions, when it has passed maturity; and not one of the natural senile developmental processes. At whatever period of life it occurs—and it is not unfrequent about sixty—it omens ill for the further prolonged wear of the fabric. It is not quite easy to put the condition of these cartilages to the test, especially in elderly persons. It may, perhaps, be best done by estimating the elasticity perceived when gentle pressure is made upon the lower part of the sternum, though there are obvious difficulties and objections to this method; and of 274 returns in our inquiry upon this point, it is as much as can be expected that the elasticity should be stated to be distinct in 126; in the remaining 148 it is said to be indistinct.

It may, I think, in like manner, be said, with regard to the calcification of the arteries, that it is the result of a morbid process intruding itself upon, interfering with, and arresting, the normal progress of senile development. That it is not, at any rate to a perceptible amount, a usual accompaniment of old age is shown by the fact that in 362 returns respecting the condition of the arteries in persons over eighty these vessels are stated to be knotty in only 40, and even in 257; they are noted as being tortuous in 71. Moreover, the pulse is reported as compressible in 311, and incompressible in 72, in the returns relating to it. In the majority of cases, therefore, the arterial system appears to present a healthy condition in those who attain to great age.

The rate of the heart's beats, according to our returns, does not vary much as age advances. From eighty to ninety, it averages 73 to 74 in men, and 78 to 79 in women. It is stated to be regular in 322, and irregular or intermitting in 85.

The respiration in 110 returns of men between eighty and eighty-five averages 17 per minute. In 47 returns of men between eighty-five and ninety it averages 19 to 20; and in 16 returns of men at and over ninety it averages 23; in women it is a little quicker. Thus, in 86 returns of women between eighty and eighty-five it averages 22; in 54 between eighty-five and ninety it is also 22; and in 37 at and over ninety it is 23. It has to be borne in mind, however, that the not unfrequent occurrence of bronchitis in the aged raises somewhat the average rate of respiration in them.

The failure of nutritive force in the brain manifests itself in the lessening of that power of concentration and quickness of attention upon which the sharp stamping of impressions and the ready recall of them depend; hence the memory for recent events is commonly impaired. The old man meanders on in his conversation unconscious that he is repeating himself; he remembers the tales of long past times, but forgets that he has just told them. This may go on to the condition of senile dementia. Happily, it does not often do so; and it is satisfactory to note how many of the very aged are in good possession of their mental faculties, taking a keen interest in passing events, forming a clear judgment upon them, and full of thought for the present and future welfare of others. It is no less satisfactory to find that the active, even severe and long-continued, functional activity of the matured brain seems in no way to impair its enduring qualities, and that good earnest useful employment of body and mind are not only compatible with, but even conducive to, longevity. A good example of this preservation of mental and bodily faculty to extreme old age was presented by Titian, who is related to have been engaged in painting a picture, which has its place in the gallery at Venice, when in his ninety-ninth year he was cut off by the plague. The wasting of the cerebral hemispheres, which is the accompaniment of failure and feebleness of the intellectual powers, diminishes the pressure in the cranial cavity, and so causes an increase of fluid in the subarachnoid lymph-spaces between the convolutions, and sometimes, as I have already mentioned, an increase in the thickness of the skull. A similar effusion into the connective tissue of other parts of the body, especially the lower limbs, probably also from deficiency of pressure upon the vessels, or lowered tension of the several tissues, is liable to take place, constituting a "senile œdema." This is no uncommon thing in the aged, and is sometimes induced by temporary causes, so that recoveries from it are not unfrequent.

Of the 157 males from eighty to eighty-five, only 6 are stated to have, or to have had, disease of the prostate or bladder; and of these, 3 had recovered from it, 1 at the age of seventy-nine, although the trouble had been of six years' duration. In one, the difficulty of micturition had existed for thirty years. Thus far, the evidence was favourable, and gave rise to a hope that, when a certain period of life had been attained, this serious and painful malady would be escaped. I find, however, that of the 72 males between eighty-five and ninety 17 are reported to be more or less sufferers from urinary troubles. In 4 of these, micturition is stated simply to be slow. In others, there is more or less irritability, or incontinence, or retention. One gentleman of eighty-eight has been entirely dependent upon the catheter for forty years. In 1 only of the 30 returns of men above ninety is there any mention of affection of this kind. On the whole, therefore, although the prospect of escape from diseases of the bladder and prostate gland is not quite as good as I had anticipated from the returns of the men between eighty and eighty-five, it is evident that the aged are, to a considerable extent, free from this source of trouble. Indeed, the aged body does not seem to be, on the whole, prone to disease. Few of the returns indicate the presence of any special malady. We know that even cancers, when they attack old persons, often make slow progress in them, and sometimes fail to make way at all, remaining stationary, or even withering; and the susceptibility to contagious diseases appears to decrease from infancy to old age. The nutritive processes seem to be most easily led astray in early life, when they are in greatest activity, when there is most receptivity and excitability, and most quick communication of impressions from part to part, and from organ to organ.

In the *British Medical Journal* of the 12th of July last I offered some remarks on the repair of wounds and fractures in aged persons. I had frequently noticed that it, as well as the healing of ulcers, takes place as quickly as in middle life—indeed, sometimes more quickly; and I gave the results of a collective investigation on a small scale, which were confirmatory of that view. Since then many instances have been communicated to me by medical men which lead to the same conclusion. I there remarked that "the statement must be qualified in a manner which savours rather of the paradoxical—namely, that wounds in old people heal quickly, provided they do not slough. That is to say, the apparently opposite tendencies exist at this time of life—namely, the tendency to slough and the tendency to heal quickly. Such, for instance, is the experience of oculists, whose testimony on the subject I have asked. They find that the cornea sometimes sloughs after the operation for cataract in old people; but that, when it does not slough, the wound heals quite as quickly as, or more quickly than, at an earlier time of life. So in other operations. The old person may sink, or the wound may slough or ulcerate; but, if these eventualities be escaped, a quick healing may be expected. Certainly this would not have been anticipated. We should not have thought, when the nutritive forces are generally failing, when strength and weight are diminishing, when repair is each year less and less able to keep pace with wear, as evinced, among other things, by the fact that exhaustion is more quickly induced and less quickly recovered from; when the brain is shrinking and memory and other mental powers are lowering, and when the circulation is becoming weaker—that, under these circumstances, the nutritive or reparative processes concerned in breach-closing—in the healing of wounds and ulcers—should manifest an increase of energy, at any rate of rapidity, in carrying on their work. I do not know well how to explain it; but this exceptional phenomenon of nutrition is not peculiar to old age. It may be observed in some other lowered conditions. The wounds in patients exhausted by large losses of blood usually heal quickly, as they also do after operations for cancer, and in many other debilitated conditions. I do not mean in persons of naturally strumous temperament, but persons who have been weakened by illness or in other ways. So do, commonly, the gaps caused by carbuncles and bedsores; and very remarkable is the quick healing of the stump left by senile gangrene; that is to say, this evidence of vital energy is manifested in the part next above that which was unable to keep alive at all. An exception must be made of certain impaired conditions of the nervous system in which wounds and sores are sometimes very troublesome."

The fact that the fracture of the neck of the thigh-bone, which may be regarded as the old person's fracture, rarely unites, will be urged in support of the opposite and more generally accepted view on this point. "It is well known, however," to quote again from the same paper, "that this failure depends, not upon the age of the patient, or on any peculiarity in the structure of the bone, or upon any changes that take place in it during the later periods of life, though those changes are such as to cause rarefaction of its cancelli and greater liability to fracture, but upon other causes. Such causes, more particularly, are the separation of the broken surfaces, which commonly occurs; the buried position of the inner fragment in the cavity of the acetabulum, which prevents any overlapping of the fragments and any throwing out of uniting matter all around it; as well as the comparative absence, and, when the fibrous covering of the neck is torn though all round, the complete absence, of tissue in which that material can be produced, and also the bathing of the fractured surfaces by the synovial fluid. That these conditions, which are found to be more or less prejudicial to bony union of fractures into other joints, and not senility, are the real causes of failure in the case of the neck of the thigh-bone, is proved by the fact that union of bone will take place at this part of the skeleton as well as elsewhere, if the fractured surfaces be fixed in apposition, either by any kind of impaction or by well-adjusted appliances;" and that this will occur in the aged, there is ample evidence in our museums.

The same remark does not, I fear, apply to the repair after exhaustion from fatigue. The old person is soon tired, and does not recover quickly. The restorative processes of sleep are not so brisk in him as in the young. I have often, however, been surprised at the quick recovery of health and strength by old persons who have been depressed by indisposition and illness; and I have attributed this rallying power to the general soundness of the system, and the good working balance of the several organs which has brought them to old age. To what extent it is, as a general rule, shared by the aged and may be relied upon in them, I must leave to wider experience to decide.

After all, length of life is to be really estimated not by numbers of years so much as by good work done, not by the amount of time spent in the tame fruitless manner indicated by the pithy words of Cowper—

> "For fourscore years this life Cleora led:
> At morn she rose, at night she went to bed"—

nor by endeavours solely to advance our own fortunes, or reputation, or comfort, but by persevering efforts to promote the welfare of our fellow-men.

Thus considered, how large have been the lives which many of you have spent in long laborious days and watchful nights, with little present gain or prospect of future requital, in the out-patient and post-mortem rooms of our hospitals, by the midnight lamp, or by the bedsides of the sick in this vast metropolis, where civilisation has worked out its best and its worst results. While wishing you yet many years of the like usefulness and its assured reward, I must express the feeling that it is not right or just that, in this the wealthiest city the world has ever seen, and in this very wealthy land, so much of the time and energies—the best time and energies—of many of the younger members of our profession should be devoted to attendance upon out-patients, and so much time of a far larger number of the profession should be employed in the onerous and anxious duties of the Poor-law service with such very inadequate pecuniary remuneration. For the sake of all concerned reform is needed here.

I will only further add that there are many points in relation to longevity which I have alluded to only briefly or not at all; that it will be evident from the few figures I have given we need more information; that the forms and memoranda issued by the Collective Investigation Committee can be obtained from the Secretary to the Committee at the office of the British Medical Association, 161A, Strand; and we shall be obliged if any of those present or other members of the profession will contribute to our store, especially by making returns of persons who have attained or exceeded the age of ninety years.

ON THE

SIGNIFICANCE OF A PECULIAR MURMUR IN RELATION TO THE DIAGNOSIS OF INTRA-THORACIC DISEASES.[1]

BY J. S. BRISTOWE, M.D. LOND.

THE various cardiac, arterial, and venous murmurs are for the most part well understood at the present time, although from various causes difficulties still, and probably ever will, arise to interfere with their correct appreciation in particular cases. Cardiac murmurs, at any rate such as are due to the valvular orifices, occur during either the cardiac systole or the cardiac diastole, never occupying the whole duration of either of these actions, and are never prolonged continuously from one of these actions into the other. The nearest approach to anything of the kind is when the first sound of the heart is preceded by a presystolic mitral and followed by a systolic mitral, an exception which, however, is apparent rather than real. Venous murmurs are continuous, and this continuousness characterises them even when they swell and sink more or less rhythmically. Arterial murmurs are of two kinds:—First, murmurs conducted by the blood stream from the aortic orifice, which, therefore, are simply basic systolic, or diastolic, murmurs slightly delayed in proportion to the distance from the heart at which they are heard; and, second, murmurs which are developed in the arteries themselves, in consequence of narrowing or dilatation of their channels, of roughness of their walls, or of some other abnormal condition. The former kind of arterial murmurs needs no consideration at the present moment; it is the latter which interests me. These murmurs are for the most part systolic—that is, they are developed during the diastole of the arteries and while the blood is flowing with its greatest rapidity along them. They are said to be also occasionally diastolic—in other words, to attend the arterial systole, at which time the blood-stream is comparatively sluggish. And hence it is often taught, I believe, that murmurs of arterial origin may be either systolic or diastolic, and may consequently, like true cardiac murmurs, be double. I doubt the truth of this teaching, and my doubts are not removed even by the able paper on this very subject recently published in the *British Medical Journal* by Dr. Finlayson. There is no alternate backward and forward flow of blood in the arteries, and consequently alternate direct, and regurgitant, murmurs cannot arise in them. In the early part of the aorta the blood remains almost stagnant during the cardiac diastole, and it seems practically impossible that its movement can at this time and in this place be productive of sound. As we pass, however, further and further from the heart, the flow of blood during the cardiac diastole becomes more and more active, until at length it gets nearly, if not quite, uniform, during the whole of the cardiac cycle of events. Now, here it seems to me quite obvious that a murmur might run through both the cardiac systole and the cardiac diastole, and that anyone taking the cardiac beat or the pulse for his guide might assume the presence of a double murmur. My belief is that such murmurs are single, that they commence at the moment the effects of the cardiac systole are felt, that they are continued through the whole of the cardiac systole while the blood is flowing rapidly, and that they are continued without break into the period of the cardiac diastole, generally with some modification of character, and die away before the occurrence of the next pulse. In other words, my belief is that arterial murmurs developed at some distance from the heart are due to the onward flow of blood, that they occur during that period in which the blood is flowing with sufficient force to produce a murmur, that they are hence apt to be prolonged beyond the period of the cardiac systole, and that it is a needless refinement, if not an error, to regard them as double in the same sense as an associated aortic systolic and diastolic murmur is double. I have on several occasions, in connexion with abdominal aneurysms, observed murmurs of the kind here referred to, which some have regarded as double, but I have held to be single, and which I have elsewhere briefly described. Murmurs closely resembling these, if not actually indistinguishable from them, may often be heard in cases of aneurysmal varix or communication between an artery and vein. But here the murmur is said generally to be continuous, and in this respect to resemble a venous hum, associated, however, with rhythmical exacerbations, due to the cardiac systole. Such murmurs may also be heard in cases of communication between the aorta and pulmonary artery, or one of the auricles. These remarks are intended to be introductory to the description and discussion of two or three cases which have many points of independent interest, but in which the presence of the kind of murmur just discussed was both a subject of dispute and an important item in forming a diagnosis.

---

[1] Read before the East London and South Essex District of the Metropolitan Counties Branch of the British Medical Association, March 19th, 1885.

CASE 1. *Pulsating cancerous tumour of right scapula, both iliac bones, and second dorsal vertebra; paraplegia; bedsores; death; autopsy.* — Catherine B——, thirty-seven years of age, was admitted under my care on July 12th, 1878. She had been married five years, but there was nothing in her history to throw light on the origin of her disease. It was after the birth of an eight months' child in the previous January that the symptoms of her present illness first showed themselves. When she got up after her confinement she felt a good deal of pain in the back between the shoulder-blades, and much pain also in the epigastrium; and these have continued ever since. She has not had much cough, but she says that of late she has spat a good deal of blood, sometimes as much as a pint in the week. She has lost flesh and strength.

The patient is a woman of healthy complexion, and looks well nourished. She complains of pains, between the shoulders running up into the neck, in the chest, in the right shoulder, and in the hips, knees, and ankles. It hurts her to move, and she generally lies on her back. The right side of the neck is somewhat puffy, the veins are large, and there is some pulsation, apparently due to the veins. Also there are a few slightly enlarged glands high up in the neck. The lung resonance and respiratory sounds are fairly normal in front. There are murmurs in connexion with the heart and large vessels which present some peculiar features. In the first place, there seems to be a systolic murmur at the apex, due to the mitral orifice; in the next place, at the base of the heart there seems to be a double murmur, which may be frictional; and, in the third place, there is a loud prolonged systolic murmur audible in the aortic area, and extending thence to the outer extremity of the right clavicle, where it seems to be especially loud; it is also distinctly audible on the right side of the neck. The heart's area of dulness is somewhat increased, and its apex is a little displaced outwards. Its action is regular, and it is thought that the pulses in the carotid and radial arteries of the right side are a little larger than the corresponding pulses on the left side. Abdomen healthy. Tongue clean; appetite poor; bowels regular; urine of high specific gravity, and containing a trace of albumen; temperature normal.

It was assumed at first that the patient had either some obscure cardiac disease or an aneurysm, and all the symptoms were attributed to this cause. But she had not drawn attention to some important features in her case, and our own examination had been incomplete and misleading. A few days after admission, a more exhaustive inquiry was made, and on stripping the chest it was found that a somewhat elastic pulsating tumour occupied the whole of the infra-spinous fossa of the right scapula. This was fairly smooth and rounded, projected about an inch beyond the level of the left scapula, yielded a sensation as of dilated vessels, and did not crackle on hard pressure as if containing plates or spicula of bone. Further examination revealed two similar pulsating tumours, one on either buttock, growing apparently from the subjacent iliac bones. The right, which was the larger of the two, appeared to be of the size and shape of a penny bun. They were round in outline, projected half an inch or so above the general level, and felt as though formed by plexuses of dilated vessels; and large, apparently varicose, veins were visible about their margins and extended from one to the other. All the tumours presented a well-marked murmur. Some of those who examined them regarded the murmur in each as double: as comprising an element corresponding to the cardiac systole, and an element corresponding to the cardiac diastole. My own view was, and repeated further examinations confirmed me in the correctness of it, that the murmur was single, but much prolonged; that it commenced with the arterial pulse or cardiac systole, continued throughout the whole of the cardiac systole, and was prolonged with some change of character into the period of the cardiac diastole. I also came to the conclusion that the sounds heard in the front of the chest were due mainly, if not entirely, to the scapular tumour, and that the supposed double murmur at the base and between the base and the clavicle was a single murmur prolonged through the systole into the diastole. This murmur, as before stated, was loudest at the outer angle of the clavicle, where its continuity was unmistakable, and diminished in intensity as the aortic area was approached, where it most presented the semblance of being an ordinary double murmur. At the apex a systolic murmur only could be heard. It was difficult to be sure whether this was simply the before-described murmur, of which the loudest portion only was transmitted, or an independent mitral murmur. There was much diffused pulsation over the whole of the cardiac area; and on deep expiration pulsation and a thrill were perceptible in the inner part of the left second intercostal space. It was further discovered that there was undue prominence of the upper three dorsal vertebræ, and much tenderness in the neighbourhood of the second and third. It may be added that she suffered from dyspnœa; and that examination of the larynx and retinæ showed these parts to be quite healthy.

The patient gradually got worse. She grew weaker and thinner, suffered constantly from severe pain referable to the regions before indicated, had considerable dyspnœa, and her tumours slowly increased in size. Latterly her pains were referred chiefly to the epigastrium, buttocks, and lower extremities; and early in November she began to show signs of paraplegia, which about the middle of the month became complete. At this time she had lost feeling and voluntary motion in the legs and control over the rectum and bladder, and a large bedsore had formed over the sacrum. Subsequently great œdema of the lower extremities supervened, a purpuric eruption appeared on the arms, and an abscess formed in one of the thighs. She became extremely emaciated and feeble, and (though continuing quite sensible) very apathetic, and died worn out on the 23rd of January, 1879, as nearly as possible six months after admission into hospital and twelve months from the beginning of her illness.

Necropsy.—The upper half of the body was much emaciated, whilst the lower part of the trunk and the legs were enormously swollen with œdema. The buttocks especially were enlarged, partly from œdema, partly from the presence of tumours. Over the sacrum was a very large bedsore, extending down to and exposing the bone. The arms and hands were studded with purpuric spots, many of which presented central vesicles. The pleural cavities were healthy, the lungs congested and œdematous. The pericardium contained an ounce or two of serum, and over the anterior surface of the right ventricle was a large milk patch, and at the apex of the heart some old thickening. The heart was generally hypertrophied and dilated, but all its valves were healthy and apparently competent. The peritoneal cavity was normal. The capsule of the liver was somewhat thickened, and the centres of the lobules were congested. Spleen small, healthy. Stomach and bowels free from disease. The urinary bladder was dilated and injected. The right ureter and kidney were healthy, but the left ureter and the cavity of the left kidney were congested and dilated. This kidney was somewhat swollen and congested, and white patches studded its cortex, and white radial streaks its medulla. Suprarenals normal. A few very small fibrous tumours were present in the uterine walls. The pelvis was removed in mass in order to be minutely examined and to form a museum specimen, but unfortunately it was allowed to spoil, and no exact record of its condition was made. The posterior part of each iliac bone was connected with a large carcinomatous mass, which had grown backwards, caused stretching and attenuation of the glutei muscles, and closely approached the cutaneous surface. Large veins meandered over the tumours and through the substance of the muscles. The hip-joints were unaffected. The tumour of the right scapula had originated in the portion of the bone below the spine, and had destroyed its whole substance with the exception of a narrow strip along the vertebral edge. Many dilated veins were seen upon the surface of the tumour, and many vessels entered its substance. Shoulder-joint healthy. The second dorsal vertebra was softened and wholly destroyed by a growth which had originated in it and grown backwards, pushing the periosteum, ligaments, and membranes of the cord before it, and thus causing compression and softening of the cord at that spot. The cord and membranes were not, however, directly involved in the growth. The brain was healthy.

Clearly there was nothing discovered in the condition of the heart or pericardium to explain the murmurs heard over the front of the chest. And I think, therefore, I am justified in concluding that the view I took of the auscultatory phenomena during life was the true one—namely, that the murmurs were due to the vessels of the tumours, and, for reasons already stated, to the arteries rather than to the veins. I was inclined at the time to attribute the loudness of the murmur at the acromion process and about the clavicle and sternum to its conduction from its seat of development in the scapula along the continuous chain of bones. I think this explanation is adequate.

ON THE

NON-MALIGNANT TUMOURS OF THE SPERMATIC CORD, AND THEIR DIAGNOSIS FROM HERNIA.

BY EBEN. WATSON, M.A., M.D.,

SENIOR SURGEON TO THE GLASGOW ROYAL INFIRMARY.

(*Concluded from p. 788.*)

So much, then, for the fluid tumours of the spermatic cord. I now come to the much more difficult subject of the solid tumours of this organ. My difficulty here arises, not so much from the want of cases in point as from the want of cases with definite and demonstrable results. The indubitable facts of ordinary anatomy, however, help us in our understanding of these cases; for it reveals to us that tmixed with the common areolar tissue of the pelvis and of he cord are numerous *small masses of fat*. These are more abundant within the pelvis, but are also sometimes found in the cord itself. Now this is true for subjects of all ages and free from morbid affection of these parts; but it is well known that at and about the middle period of life fat naturally increases in the body, and especially in the abdomen. Nothing, then, is more likely than that these nodules of fat should at that time increase so as to deserve the name of tumours. Hence we are well prepared to receive the statement of pathologists that non-malignant tumours of the cord are either fatty or fibrous (areolar), or a mixture of both, and my experience, so far as it goes, confirms this statement; but I have not more than one actual dissection[1] to contribute to those already on record, for most of my cases are still alive, and therefore perhaps still doubtful. A good example is the following:—

A middle-aged man from the country called at Mr. Hilliard's shop to get a truss for what he thought was an inguinal hernia; but Mr. Hilliard, on examining it, differed from him, and at least thought it was so unusual in its characters as to induce him to advise the patient to see a surgeon when in Glasgow. He therefore consulted me, when I found a small soft inelastic tumour passing from the right inguinal opening. It could not be separated from the cord when the patient was standing up. It gave a distinct but slight impulse on coughing, and entirely disappeared in the recumbent position. It was noticed, however—and this I think important,—that whenever the patient stood up the tumour was there in its old place, as if it simply hung forward again owing to the patient's change of position. When the patient coughed while in the recumbent position the impulse given to the tumour could be both felt and seen, but whenever the cough ceased, or in the intervals between his coughs, the tumour disappeared. This would not likely be the case with a recent oblique inguinal hernia, which, when coughed down, generally remains down until put back by the hand. Of course the tumour in this case had no gurgling as if it contained bowel, but felt smooth and soft, and slipped readily from the fingers to either side of the inguinal opening, into which it could be easily pressed in any position of the body. It had existed probably for a long time, and the man could not tell how his attention had been drawn to it, but when he discovered it he at once consulted his doctor in the country, who advised him to wear a truss, but it had not kept it up rightly, and hence his visit to Mr. Hilliard. I did not think this a hernia, even of omentum, but a small portion of fat—a lipoma, in short, connected with the upper part of the cord, or possibly an instance of what Cloquet actually found on dissection, and described in his work on Hernia—viz., a portion of fat belonging naturally to the areolar tissue of the pelvis, which had increased unduly and protruded through the inguinal canal. This would no doubt better account for the impulse on coughing and the disappearance of the tumour in the recumbent position. I therefore did not press the continuance of the truss; but as it relieved the man's mind to wear it, I advised that it should be of the slightest power of spring. It is nearly two years since I saw this man, but I have heard from Mr. Hilliard that he lately saw him, much improved in health, but with the little tumour quite unchanged in size or appearance.

I could relate, if *necessary*, the details of other two cases, which I still occasionally see, of precisely similar kind, only they have to my knowledge continued much longer without appreciable change. In one of these cases a slight truss has long been worn, in the other no artificial support has been employed, and both patients are very active in their habits, and enjoy quite good health. It may be worth mentioning that in the latter of these cases a truss was at first applied by the advice of another surgeon, but it was found that the little tumour constantly slipped to one side of the pad, and caused a disagreeable sensation of pinching to the patient. He therefore gave up using it, and without any increase of the tumour, though it is nearly ten years since he first accidentally noticed its presence.

I believe that these are cases regarding which there may be much difference of opinion, especially when stated in writing without examination of the patients, or unless those who read them have had experience of some such cases for themselves. I can only say that these tumours differ from omental herniæ, with which they are alone comparable, in that they are absolutely painless and quite destitute of that dragging feeling characteristic of true epiploceles. They are quite smooth, of a regular oval shape, almost fluctuant, and slide about more widely than herniæ. These characters of tumours of the cord may be so far definitely given and appreciated without further explanation. It is not so, however, with the other two, which are perhaps the most important of all—viz., the impulse on coughing and the disappearance in the recumbent position. Let us, therefore, consider these a little more particularly.

1. When the tumour is situated high up the cord, and indeed belongs partly to the abdomen, the impulse on coughing may be as distinct as that of an omental hernia; because in such an act pressure is made equally on all the contents of the abdomen, and must tell on the tumour as it would on an omental protrusion; but as the tumour grows and descends towards the scrotum, which it naturally does by its own weight, this impulse on coughing greatly diminishes, and so it happens that in most cases, before a surgeon is consulted at all, that sign is absent, or at all events quite distinguishable from the direct and forcible impulse given to a hernial protrusion, for it is then easily perceived that the tumour only partakes of the general succussion given to the whole side of the abdomen.

2. In like manner, when the patient lies down, the tumour, if small and soft and partly contained in the abdomen, may entirely disappear into the loose areolar tissue above the internal inguinal opening; but when it grows larger it cannot wholly disappear, and must remain partially in the canal, where it may be felt rolling under the surgeon's finger, and whence it falls out apparently by its own weight, more quickly than a hernia, whenever the patient stands upright. In this, perhaps, it is assisted by the elastic reaction of the posterior wall of the inguinal canal, and the tension of the conjoined tendon produced by the action of the abdominal muscles; for it is only by weakness, or at least, relaxation of that tendon, that the tumour is permitted to conceal itself in the canal. It must be remembered, too, that the spermatic cord slips up or is pulled up by the cremasteric muscle much higher in some subjects than in others;

---

[1] When operating in a case of strangulated hernia, on May 2nd, 1885, I found a small fatty tumour, about the size and thickness of one's thumb, connected with the outside of the hernial sac. I excised it before introducing a suture into the inguinal opening.

and of course any tumour of its substance, if soft and yielding like lipoma, would go along with it, and this has suggested to me to try if traction on the cord would make the tumour descend. I think this manœuvre, if done very gently, does somewhat change the position of these tumours, and I am quite certain that it greatly diminishes the impulse given to them on coughing. Of course this arises from the traction freeing the tumour from contact with the posterior wall of the canal, and would afford good corroborative evidence of its real nature in a doubtful case. In some of these cases, however, the tumour grows both a great deal harder and larger in time, and loses many of the above characters, becoming much like incarcerated omental hernia, as in the following example:—

A man, aged forty-four, was admitted into the Glasgow Royal Infirmary on March 19th, 1884, and told us that he believed he had had a rupture on the right side for many years. It was small and reducible at first, but about seven years ago it greatly enlarged in the groin and gradually descended into the scrotum, where it still further enlarged. He averred that even then it was reducible in bed. He wore a truss, which did not at all keep it up, and seemed only to have pressed on the neck of the tumour. For the last eighteen months it had been quite irreducible and almost quite hard, but was painless to the touch. Such was the state of matters when on March 13th, six days before admission, the man was seized with violent pain in the lower part of the abdomen, but not any in the tumour. His bowels were easily and freely moved with medicine, and he had no sickness. Fomentations were applied and opiates given, so that when he came to the hospital the pain had been very greatly relieved. But the tumour is thus described in the ward journal: "It is about the size and shape of a large Duchess pear, the thin end passing up into the inguinal canal, while the bulk of it occupies the right side of the scrotum. It is at present painful to the touch, because the skin over it is red and œdematous. It is quite irreducible, and gives no impulse on coughing." His bowels had been freely opened the day before admission. Fomentations were applied, and next day castor oil was administered, and acted freely. The pain of the abdomen had ceased, but the tumour was unchanged, and remained so until April 2nd, when I explained to the man that without an operation he could not be relieved. To this he consented, and next day, having put him under chloroform, I cut down upon the tumour, and found it covered by the sheath of the cord, and closely adherent to it and to the testicle. There was not a particle of fluid in the sheath, and it was with difficulty separated from the surrounding parts; this was, however, effected by dissecting from beneath upwards. It was then seen that the narrow part of the tumour was enclosed in the inguinal canal, and adherent to it all round, and giving no sign of its passage into the abdomen. I incised fully one-half of the canal to make sure of this, and then, being quite satisfied that I had simply the fibrous neck of the tumour to deal with, I pierced it with a needle armed with a long chromatised catgut ligature, both ends of which I tied so as to surround the transfixed part, and then I cut it off below the ligature, having succeeded in saving both cord and testicle from injury. Lastly, I made a free opening through the lowest part of the scrotal cavity, which had contained the bulk of the tumour, and, having inserted a drainage-tube, stitched up the main wound. The usual antiseptic dressings were applied. On cutting into the tumour, it was found to be fibrous in its nature, and quite hard and solid throughout its entire extent; but on submitting sections of it to microscopical examination, it was found that the fibres were here and there separated by small masses of fat. In the future progress of the case nothing remarkable occurred. For a few days there was some swelling of the soft parts on the wounded side of the scrotum, and very little discharge of pus. Nevertheless, the wounds healed slowly, and it was not till April 26th, twenty-three days after the operation, that it was noted that they had quite closed up. The scrotum had then regained very nearly its natural size, and there was no hernial protrusion to be detected on the most violent coughing, whatever the position of the body. The patient was kept under observation in the hospital for some weeks longer, and then dismissed cured.

I must remark on this case that its early history does not seem to me quite reliable, but it is clear enough that the truss did not and could not do any good. Nay, I believe it rather increased the irritation and hastened the growth of the tumour by pressing on its neck. Of course it would, in some respects, have been better had the patient applied earlier for surgical assistance, for the tumour would then have been smaller and less adherent to the sheath of the cord. Indeed, one feels amazed that the very weight of the tumour did not cause him to seek its removal; but the truth is that these tumours seem to be so devoid of pain, and to affect the health so little, that few patients would submit to an operation even if proposed to them at an earlier period in the history of the growth, and such growths naturally increase so slowly that, unless irritated by wearing a truss, they may never cause trouble or inconvenience at all (even by their weight and bulk), and therefore may be safely let alone, especially if the patient is at or beyond middle age. Nevertheless, all such cases ought to be watched from time to time, and if there should occur pain or much increase of size, or any decided fixation of the tumour as from adhesions between it and the parts of the cord, an operation may then be considered desirable for its removal; but I do not, as a general rule, advocate a too ready recourse to the knife in such cases.

The only question which remains for consideration is the advisability of the patient's wearing a truss at the first. Now, take the case—and a rare one it must be—where one sees a patient while the tumour can be completely reduced above the internal opening of the canal. It may well be asked, What good could it do to keep the tumour inside the abdomen? and would its increase there not do more harm than if allowed to pass out of the canal? Then, in the commoner case, in which part of the tumour remains in the canal, it is obvious that the pressure of a truss may do harm, especially if the patient is a working man. But if it is allowed to remain there, it may next be asked, Will there be no danger of permitting the descent of a real hernia by the dilatation of the internal inguinal opening and of the canal itself caused by the presence of the tumour? Now, for my part, I think this fear unnecessary, for the tumour rather protects from such an occurrence by its presence and by the consolidation of the infundibuliform fascia which it naturally causes, and which was abundantly evident to me when operating in the case last related in this paper. Besides, there is, in all such cases, the unimpaired form and saccular continuity, if I may so call it, of the peritoneum, which we have good reason to think is in itself a protection against a hernial protrusion. On the whole, then, I do not recommend the use of a truss in these cases unless it relieves anxiety in the mind of the patient; but I should certainly forbid it if it caused any irritation or pain in the tumour. I need hardly add, in conclusion, that whenever symptoms of strangulation are present, it is the duty of the surgeon, without delay, to cut down on any tumour in the inguinal region, however doubtful he may be of its exact nature, and then to deal with it according to what he finds it to be.

A CONTRIBUTION TO THE

CLINICAL STUDY OF THE LIVER VIEWED THROUGH THE URINE.[1]

BY GEORGE OLIVER, M.D. LOND.

NO. II.—THE PHYSIOLOGICAL AND CLINICAL ASPECTS OF THE BILE SALTS IN THE URINE.

AT the last meeting of the Leeds and West-Riding Medico-Chirurgical Society I demonstrated the capacity of an acidified solution of peptone as a practical test for the detection and quantitative observation of the biliary salts in the urine; and I showed how well adapted it is to serve clinical requirements in this direction. I now propose to bring forward such physiological and pathological data as this new instrument of clinical observation has brought within my grasp.

1. *The Renal Elimination of Biliary Salts in Normal Urine.*

Bile salts in healthy urine indicated by the peptone test.—Some few years ago that sagacious observer, the late Dr. Murchison, remarked that "not only in jaundice, but in health, a portion of the bile pigment, as well as of the bile acids, formed in the liver is absorbed into the blood"; if so, may we not expect to find a small quantity of the central components of the bile (the biliary salts), or a derivative of them, in healthy urine?—providing, of course, they are not completely broken up by chemical action,[2] and the mode of direct testing is sufficiently delicate for the purpose of detection. When it is remembered that in man the liver secretes on an average each day not less than four ounces[3] of bile salts, it will surely not be surprising if a fraction, as it were, of this large quantity should, under the ordinary conditions of health, get adrift from the portal into the general circulation, and be discharged by the kidneys; in fact, were the amount of these leading biliary constituents but half that just indicated, the non-appearance of a small portion of it in the urine would, I think, be regarded by most physiologists as improbable, being contrary to anticipation suggested by kindred data.[4] Certainly so far the biliary salts of the blood have not been isolated; but their absence cannot be inferred from this negative evidence, for the quantity is doubtless too small for separation and detection by the methods hitherto employed. It is not so, however, with the urine; for the bile acids have been separated by Naunyn and Draggendorf in healthy non-jaundiced urines; and lately Lépine and Guérin have shown that the greater part of that portion of the unoxidised sulphur present in the urine which is oxidised with difficulty by reagents is derived from the bile by the reabsorption of taurocholic acid.[5] Then, again, it has been demonstrated that taurin—derived from taurocholic acid—is eliminated in small quantity by the healthy kidney. I therefore conclude that the diminutive reaction of the peptone test solution with normal urines accords with the presence of a trace of bile salts discovered in them by physiological chemists.

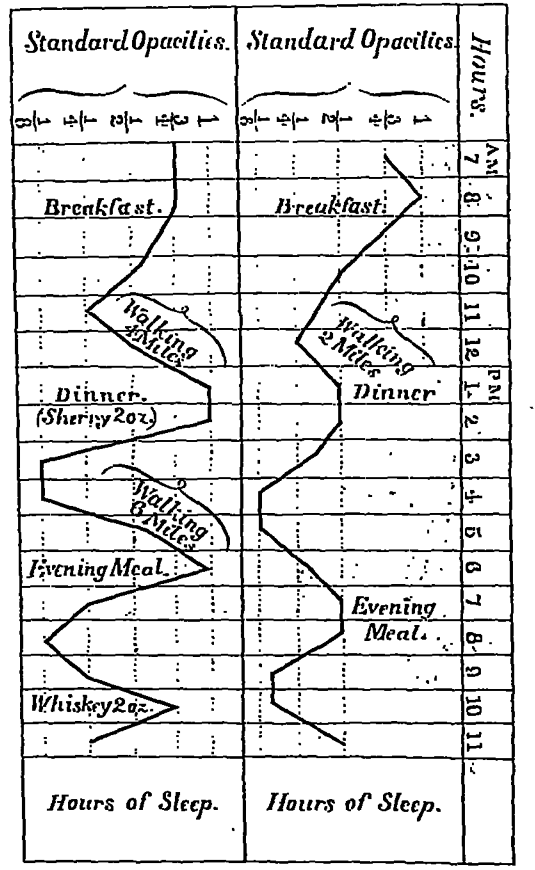
---

[1] Read before the Leeds and West-Riding Medico-Chirurgical Society, May 1st, 1885.

The amount of bile salts present in the normal urine of the same individual varies at different periods throughout the twenty-four hours; the causes of variation.—A large number of observations on the urine of healthy persons with the peptone solution has demonstrated the fact that the colourless biliary derivatives are discharged by the kidneys in varying proportions at different times in the course of the day. Though always present, they are increased at certain periods and diminished at others, and I find this variation definitely hinges on the digestive act.

The subjoined diagram represents hourly estimations of the bile salts in the urine of a healthy adult, aged forty-four, on two consecutive days, when every sample of urine was reduced to the uniform specific gravity of 1008, and the degrees of opacity, induced by mixing sixty minims of the diluted urine with the same quantity of the test solution, were registered according to a determined scale represented by the figures 1, ¾, ½, ¼, ⅛. It will be observed that the maximum amounts appear during the periods of fasting, as in the urine passed in the morning and before meals, and that the proportion falls quickly, generally in an hour, after each meal, and attains its minimum in from three to four hours. It would therefore appear that the renal elimination of the biliary salts is the converse of the bile flow into the duodenum; for, according to the facts provided by biliary fistulæ established in the dog, the discharge of bile into the bowel rises rapidly immediately after eating, reaches its maximum in from two to six hours, and returns to its minimum by the time of the next meal, but never ceases, even though fasting is prolonged. According to my observations, this central fact is modified by various hygienic conditions, among which exercise is the most powerful. On comparing the diagrams—one representing the subject walking only two miles, and the other ten miles—we note that, when the exercise was insufficient, the waves of increased elimination before dinner and the evening meal were imperfectly developed, attaining to merely the half standard opacity, and that when the walking was extended to ten miles the renal discharge of the biliary salts following the digestive fall reached the highest degree. It is pretty clear that moderate exercise invigorates the digestive process; for with a fair amount of walking between meals, the withdrawal of the bile salts from, as well as the return of them to, the urine, is rendered more decisive and speedy than when a lounging life is led. Indolence therefore either favours the retention of these colourless excreta within the systemic blood (cholæmia), or causes them to linger within the limits of the portal circulation, and prolongs each digestive effort. The systemic overflow of the biliary salts is probably influenced by other hygienic conditions: such as meteorological changes of temperature[6] and of atmospheric pressure, the nature of the diet, and alcohol. Though I have not yet studied with sufficient care the effects of alcohol on the renal elimination of these elements, I think I am justified by the few data observed in expressing the belief that in the first instance it is a checking agent, and then—after inducing congestion of the liver—it brings about an increased discharge, which may be even detected during the periods of digestion, when ordinarily the renal overflow of the biliary excreta is at its minimum. Should these positions be confirmed by further observation, it would seem as if alcohol should be classed with indolence as a cause of cholæmia and congestion of the portal system, and is therefore the opposite of exercise. It should be remembered that the urine of patients does not present such great variations in the amount of bile salts as are indicated by the diagrams constructed from hourly observations; for as a rule it is allowed to collect in the bladder for several hours together, and thus acquires a more uniform charge. When, however, the bladder is cleared just before a meal, the urine voided two or three hours afterwards will in health show the digestive withdrawal of the biliary salts. In order to judge of the renal elimination of these constituents the observer should select the urine of

The hourly Elimination of Bile Salts by the Urine, showing the Effects of Digestion and Exercise.



---

[2] Frerichs as well as Murchison believed that the bile acids normally absorbed into the blood from the liver were metamorphosed by oxidation into other products.

[3] According to Bidder and Schmidt, the daily bile flow of a man weighing 140 lb. is about 50 oz., and the charge of bile salts over 8 per cent., or a little over 4 oz. If it be supposed that a portion of the bile discharged into the bowels is absorbed into the portal blood and is re-secreted, the fact of a large quantity of bile salts constantly circulating in the portal system still remains.

[4] My experimental data, derived from the observation of the viscera of the ox and sheep, show that during digestion the mesenteric glands contain more of the colourless biliary elements than the parenchyma of the liver. The amount that passes by this channel towards the blood is indeed very considerable. I hope to refer to this subject in the addendum to this paper.

[5] See THE LANCET, vol. i. 1885, p. 307.

[6] A chill, for instance, increases the urinary bile salts. This fact has, I take it, some bearing on the etiology of so-called "catarrhal" jaundice and hæmoglobinuria.

fasting, before breakfast, and of digestion, two hours after breakfast; or he should obtain a sample of the whole twenty-four hours' discharge.

2. *The Clinical Significance of the Renal Excretion of Biliary Salts.*

Data provided by experiments on animals.—A review of the facts provided by the injection of the bile salts into the blood of animals (mainly dogs) forms a fitting introduction to the study of the clinical aspects of the renal excretion of these colourless biliary derivatives. The following symptoms and structural changes have been recorded by several observers (Feltz, Kitter, Röhrig, Albers, and others). (*a*) Pulse and respiration retarded. (*b*) Arterial tension and temperature lowered. (*c*) Food refused, and loss of flesh rapid; vomiting of bile and blood. (*d*) Diarrhœa: bilious, sometimes bloody. (*e*) Hæmolytic changes, capillaries obstructed and hæmorrhages. The blood more fluid than normal, and less coagulable. The red discs dissolved,[7] and the serum red-coloured from liberated hæmoglobin, and milky from fat granules and increase of fat. The passage of the blood obstructed in the capillaries: the red discs flow together *en masse.* (*f*) Parenchymatous degeneration of glands, muscles, liver, kidneys, &c. (*g*) Tetanic convulsions, followed by coma and death. (*h*) Urine albuminous, and red from dissolved hæmoglobin. The symptoms and tissue changes vary with the amount of bile salts injected: thus, it is always needful to administer certain large and repeated doses in order to induce convulsions, coma, and death; but a small quantity will produce the analogue of a bilious attack, when there is merely observed retardation of pulse and respiration, lowering of arterial tension, refusal of food, vomiting, and perhaps diarrhœa.

The balance between production and elimination.—The biliary products discharged into the bowels are mainly utilised in digestive work; and a certain comparatively small portion of them must pass out with the fæces, or good health is out of question; unless, perhaps, the renal elimination can in some degree compensate for the intestinal failure. As a rule, however, when either of these channels, by which biliary matter is normally excreted, is obstructed, and, above all, when both are embarrased or blocked, the blood becomes surcharged with the poisonous excreta (cholæmia), and then the experiments on animals become living facts in our clinical experience: the form of blood-poisoning being acute or chronic, mild or severe, or individualised by idiosyncrasy of tissue, or by special concomitant conditions, such as fever and the like. When, therefore, the balance which subsists in health between the production of these poisonous products and their elimination is disturbed, disorder or disease is induced; as surely as the smoky atmosphere of a room is the natural consequence of a narrowed or obstructed chimney. The clinical observation of the bile salts in the urine appears to me to resolve itself into the detection of an excess and of a check to elimination or of an insufficient discharge.

(*To be continued.*)

A NEW METHOD OF ADMINISTERING AND ECONOMISING NITROUS OXIDE GAS.

BY FREDERIC HEWITT, B.A., M.B. CANTAB.,

ADMINISTRATOR OF ANÆSTHETICS TO CHARING-CROSS AND THE NATIONAL DENTAL HOSPITALS.

IT has been stated that pure nitrous oxide gas when inhaled is not decomposed, and that the expired gases from a patient under its influence contain no products of decomposition which can be attributed to chemical changes in the gas during its period of association with the circulating blood. Experiments have been made not only in support of this statement, but also to prove that nitrous oxide gas is absorbed to a considerable extent by the blood.

If nitrous oxide is exhaled in much the same condition as it is inhaled, what are the reasons against our employing a comparatively small amount of it over and over again for anæsthetising a patient? If a bag containing two gallons of gas be taken, and its contents inhaled and exhaled through a face-piece devoid of valves, an imperfect form of anæsthesia is as a rule obtained. I have tried this method on several patients, some of whom have been satisfactorily anæsthetised; but as a general rule struggling and excitement supervene and become more marked during the ensuing operation, whilst the corneæ retain their sensibility for a considerable period. Sometimes, indeed, it becomes impossible to render a patient sufficiently unconscious for operative procedures. The reason of these untoward manifestations is obvious; the air which was originally present in the respiratory passages dilutes the small amount of gas to such an extent that the usual evidences of the gas having become mixed with atmospheric air ensue. The carbonic anhydride which is exhaled is supposed by many to intensify the action of the nitrous oxide; but may it not have the effect in the above experiment of rendering the nitrous oxide anæsthesia imperfect, considering that such a small amount of gas is taken for inhalation? Mr. Coleman was in the habit of causing the carbonic anhydride to be absorbed by passing the exhaled gas over lime. By these means he endeavoured to economise the nitrous oxide, but the method soon fell into disuse. The apparatus he used was cumbrous, and I do not know whether he ever took means to prevent the air originally present in the lungs from becoming mixed with the gas.

If we admit that nitrous oxide is not decomposed by the blood, and if means are taken to first get rid of air in the lungs—to wash out, as it were, the respiratory passages by nitrous oxide,—it seems to me that, with a small amount of the latter gas, it should be possible to induce a satisfactory form of anæsthesia by allowing the patient to breathe the gas over and over again. The carbonic anhydride which will still be exhaled will, according to some, be rather an advantage than otherwise; but if there is reason to believe that this gas intensifies the action of the nitrous oxide by producing an anæsthesia of its own, or if there is reason to suppose that it acts somewhat as a diluent to the nitrous oxide, then it follows that, by first flushing out the lungs by nitrous oxide, and, secondly, by depriving the circulating gas of its carbonic anhydride, it should be possible to employ a comparatively small amount of nitrous oxide with the same satisfactory result as that which obtains when a large amount is inhaled and exhaled in the usual manner.

With the object of inquiring into the above interesting questions I had occasion to devise a face-piece which I shall describe below. By the use of this face-piece I was enabled, without removing it from the patient's face, to allow a portion of the contents of a two-gallon bag filled with nitrous oxide to escape, after inhalation, through an expiratory valve, and then, by suddenly depressing a small rod, to cut off all valve action, and to allow the patient to inspire and expire the gas remaining in the bag. I spoke to my friend Dr. Percy Frankland, and he has been kind enough to make with me some analyses of expired gas from patients under the influence of nitrous oxide. These analyses we hope to be able to publish shortly. In the meantime I venture to describe the face-piece used in my experiments, as by its employment I have anæsthetised satisfactorily more than a hundred patients at the National Dental Hospital, using for each administration not more than two gallons of gas.

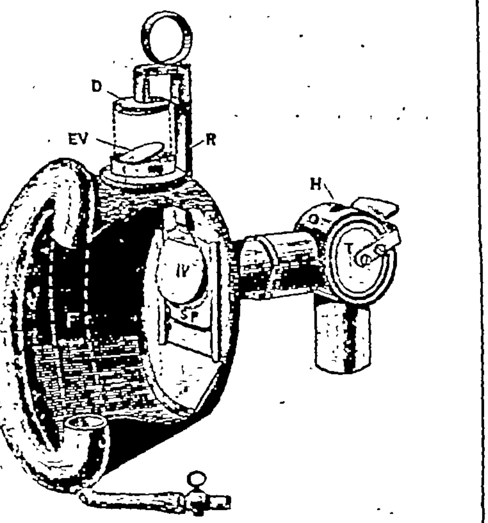
I have collected samples of expired gas under three different conditions:—1. Two gallons of gas employed. Face-piece without valves. 2. Two gallons of gas employed. Face-piece as in woodcut. Varying amounts of this gas exhaled into air before allowing the patient to breathe in and out of the bag. 3. Several gallons of gas inhaled from a gasometer and exhaled into air; having thus disposed of air in the chest, the patient was made to breathe and rebreathe two gallons of gas, previously placed in communication with the face-piece. When employed with certain simple precautions, the method adopted in the second series of experiments gave, as a rule, very satisfactory results. With regard to the carbonic anhydride exhaled, I shall abstain from making any remarks until the analyses are completed. The method which I have used for absorbing this gas is to allow the inhaled and exhaled gases to pass between two thin-walled cylinders of india-rubber sponge, soaked in a saturated solution of caustic potash. I have not made a sufficient number of experiments to arrive at any definite conclusion as to the advisability of absorbing carbonic anhydride when a small amount of gas is used for inhalation. The method I shall presently describe does not provide for the absorption of carbonic anhydride

---

[7] When a solution of the bile salts is added to a drop of blood, under the microscope the corpuscles rapidly disappear. Hünefed was, I believe, the first to record, some forty years ago, the fact that bile dissolved the blood-corpuscles.

Whether the absorption of this gas would have the effect of rendering the anæsthesia even more perfect remains to be seen by experiment.

I now propose to describe the apparatus before alluded to, (see woodcut). The face-piece (F) is furnished with two valves, an inspiratory valve (IV), and an expiratory valve (EV). The inspiratory valve (IV) is mounted upon the sliding plate (SP), which can be moved up and down by the rod (R) which is attached to it. When the plate (SP) is raised, as in the woodcut, the valve (IV) is in contact with the orifice of the tube coming from the two-way stopcock (T), and gas rushes past it during inspiration, but not during expiration; when, however, the plate is pushed down by the rod (R), the valve (IV) is also displaced, and gas can pass backwards and forwards through the orifice previously guarded by the valve (IV). The expiratory valve (EV) is situated upon the upper part of the face-piece. When the rod (R) is raised, as in the woodcut, the valve (EV) is capable of acting during expiration; when, however, the rod (R) is depressed, the circular damper (D) is pushed down upon the valve (EV), and the latter is rendered inactive. It will therefore be seen that when the rod (R) is raised, both valves are capable of acting; when, however, the rod (R) is depressed, all valve action is suddenly abolished, and gas can only pass in and out of the orifice of the tube previously guarded by the valve (IV), the rod (R) which necessarily comes over this orifice offering practically no obstruction to the passage of the gas. The two-way stopcock (T) s fixed on the one side to the face-piece (F), and on the other to a piece of tubing connected to a Cattlin bag holding wo gallons of gas. The latter (as is commonly the case) is illed from the gas-bottle through a stout piece of india-rubber tubing; and I have found it convenient to have a small stopcock with a bayonet joint interposed between the bag and the gas-bottle, so that the two may be quickly and readily disconnected, if necessary. The anæsthetist can, under these circumstances, attach the bag by any simple contrivance to his coat button, and with the two gallons of gas and the face-piece he is equipped for most short operations.



The following are the details of the method: the bag and the tubing between it and the face-piece having been filled with gas (by placing the two-way stopcock as in the figure), the face-piece (which is also arranged as shown), is accurately fitted to the patient's face. It will be seen that the face-piece is so made that it can be grasped firmly at its back part by the hand of the anæsthetist, whose forefinger and thumb will then be able to press its sides over the nose of the patient. Inspiration now takes place through the air-hole (H) of the two-way stopcock, and expiration takes place through the valve (EV). I am in the habit of testing the fitting of the face-piece by placing my finger for a moment over the air-hole (H), and then asking the patient to "try to breathe." If no air enters at any part, the sides of the face-piece will be observed to fall in as the tendency towards a vacuum is set up; whereas if air should gain admission (as it sometimes does) between the face-piece and the face, there will be slight, if any, falling in of the sides of the former, and, in all probability, some noise of in-rushing air will be audible. Having adjusted the face-piece satisfactorily, gas is turned on at the stopcock (T), and a certain number of expirations are allowed to escape through the valve (EV). As far as my experience goes, it is best to allow nearly one-half of the contents of the bag to be inhaled, and then exhaled into the surrounding atmosphere; and to effect this, four or five respirations are usually requisite. The rod (R) is then depressed. The patient now breathes directly in and out of the bag, and the usual evidences of anæsthesia ensue. The total number of respirations necessary will, of course, vary with each individual patient; the average number in one hundred cases was forty-five. I usually wait for some slight twitching of the muscles before removing the face-piece. The period of anæsthesia which ensues is, I think, not quite so long as that which is met with under ordinary circumstances, although Mr. Read, one of the dental surgeons at the National Dental Hospital, assures me that he sees no difference in this respect between the anæsthesia which is obtained by using plenty of nitrous oxide and that induced by administering two gallons in the manner I have described. I have been unable to ascribe any unusual after-effects to this mode of administering the gas. Further experience is necessary before more detailed comparisons can be made between the anæsthesia thus induced and that obtained by employing several gallons of gas.

The experience I have had in the above method of administering nitrous oxide gas has led me to the conclusion that it can be employed in all short operations, especially in hospitals where economy has to be considered. I believe that the average amount of nitrous oxide used for each patient at the National Dental Hospital is five or six gallons when the ordinary apparatus is employed. At hospitals where small fees are charged for the privilege of having the gas administered, it might be possible to reduce or abolish these fees, except under special circumstances.

Economy in nitrous oxide is doubtless to be secured in others ways than that which I have mentioned. Many anæsthetists use the "Supplemental Bag," which can be adapted to ordinary face-pieces, and by its use less gas is certainly necessary than under ordinary circumstances. How much less will, of course, depend upon various conditions. I believe, however, that, as a rule, it is necessary to use a great deal more than two gallons of gas. If two gallons of gas will suffice for short operations, it may be found practicable for the anæsthetist who is called to administer gas to one patient either to dispense with the heavy gas-bottle or to substitute for it a much smaller and more portable one.

Mr. Hawksley of 357, Oxford-street, is the maker of the face-piece; and I have to thank him for the care and attention with which he has carried out my instructions.

Somerset-street, Portman-square, W.

NOTE ON A

CASE OF OSTEO-ENCHONDROMA OF THE CEREBELLUM.[1]

BY CHARLES ATKIN, F.R.C.S. ENG.,

HOUSE SURGEON, INFIRMARY, SHEFFIELD.

MR. SHAW, of Attercliffe, Sheffield, in making the post-mortem examination on the body of a boy aged eleven, found a hard bony substance in the right lobe of the cerebellum. The cause of death was meningitis following otorrhœa of only three weeks' history. In the right lobe of the cerebellum, embedded in the substance of the organ underneath the grey matter, was a hard body about the size of a bean, half an inch by three-eighths of an inch, weighing seventeen grains. It was not enclosed in a cyst or surrounded by any undue vascularity or softening, and had apparently nothing to do with the cause of death. It was single, no smaller one being in the neighbourhood, quite firm and hard, giving at once the idea that it consisted of bony tissue. The mother stated that he has always been a delicate boy, especially up to the age of four, suffering from "water on the head," that he was late in teething, had never had scarlet fever or measles, and had always been lively, attentive, and quick at learning. The parents were apparently healthy, though the father had a strumous phthisical appearance, and three brothers aged respectively nineteen, fourteen, and nine all had otorrhœa.

---

[1] Read before the Sheffield Medico-Chirurgical Society, April 23rd, 1885.

The interest of the case lies chiefly in the origin and nature of the growth. After decalcification the bony tumour was carefully cut in two, one half being cut up into sections for the microscope and the other preserved in spirit. On viewing the cut surface the growth was seen to consist of two portions: one, a central nucleus with prolongations, and the other surrounding tissue of evidently different structure. Under the microscope four different tissues are seen—first, the stellate nucleus, consisting of fine granular matter readily taking aniline colours, staining yellow with picro-carmine; secondly, well-marked hyaline cartilage, forming a complete capsule for the nucleus, which sends its prolongations in and amongst it in a very irregular manner; thirdly, some true bone, and most externally parallel bundles of fibro-cellular tissue, which were, previous to decalcification, as hard as bone. There is no doubt that the tumour is perfectly innocent; it is not a chondrifying or calcifying sarcoma; it is not a mass of brain sand. In the granular centre, brain elements, such as Deiter's cells or Purkinje's corpuscles, are absent. One might imagine that it might be degenerated additamentary corpus dentatum, but even then the stellate cells are wanting. Is the nucleus of the tumour hypertrophied neuroglia due to circumscribed encephalitis? I have searched for records of similar growths, but have found nothing at all comparable to it. Calcifications of tumours of the brain are uncommon, but still well known. Bevan Lewis has recorded a calcified angioma, and Ross quotes one by Meschede. As well as with regard to its seat and the fact of its causing no symptoms, it is curious in another way—viz., that it is an exception to the rule that heterologous enchondromata are generally malignant.

GUY'S HOSPITAL.

DISTENSION OF FRONTAL SINUS TREATED BY INCISION AND DRAINAGE; CURE.

(Under the care of Mr. Higgens.)

Distension of the frontal sinuses from the accumulation of fluid is somewhat rare, especially when the fluid is non-purulent. Incision, with the application of the trephine, when the bone has not been absorbed from pressure or removed by disease, followed by free drainage, is the best treatment. In addition to the ordinary external opening, Mr. Higgens made one from the distended sinus into the nasal cavity, thus providing further drainage and allowing the external wound to close at an earlier date.

Eliza H——, aged eleven, admitted July 20th, 1884. The history was that usually given in these cases—a blow across the nose from a fall six or seven years previously. Some eighteen months later the child had scarlet fever, and at that time a small abscess formed at the inner canthus of the right eye; this burst and gave no further trouble. Two years ago the right eye began to water, and a swelling appeared at the side of the nose; this has gradually increased. On admission there was a fluctuating swelling surrounded by irregular bony edges, situated at the inner angle of the right orbit rather above the position of the lacrymal sac. The swelling is rather larger when the patient is in the erect position than when lying down; it is also rather smaller in the morning than later in the day.

July 21st.—An incision made into the swelling gave exit to a large quantity of thick, opaque, yellowish discharge; the finger passed through the incision entered a considerable cavity. An opening was made through the lower part of the cavity into the superior meatus of the nose, and a drainage-tube passed through it and out at the right nostril, and left with one end projecting through the incision and the other through the nostril. The drainage-tube remained in position till November 10th (nearly four months), when it was removed.

Dec. 8th.—Opening where drainage-tube projected quite closed; replaced by small depressed cicatrix. An irregular bony edge can still be felt, but the fluctuating swelling has entirely disappeared.

LIVERPOOL ROYAL INFIRMARY.

SUICIDAL WOUND OF NECK TREATED BY TRACHEOTOMY AND THE INSERTION OF DEEP SUTURES; REMARKS.

(Under the care of Mr. Reginald Harrison.)

For the following notes we are indebted to Mr. H. Pearson.

H. O——, aged fifty-six, no occupation, a weakly and ill-nourished looking man, was brought to the Royal Infirmary early on the morning of July 29th, 1884, with a severe wound in the neck, as follows: There was a deep cut on a level with the upper border of the thyroid cartilage, and extending, on the surface, about two inches to either side of the middle line; this wound, inflicted by a razor, passed horizontally backwards, so as to divide all the structures attached to the upper border of the thyroid cartilage, and, still deeper, dividing the pharynx nearly half way through. On making efforts at swallowing, the thyroid cartilage moved upwards and forwards through the wound in a most curious way. It was stated that he had lost a quantity of blood, but there was no bleeding of consequence on his arrival at the hospital. The following treatment at once suggested itself: to perform tracheotomy, and then to bring the divided parts together with strong deep wire sutures. To the attainment of this object the patient was anæsthetised, and the trachea opened above the isthmus; a large tube was inserted so that respiration might be as free as possible; next, the base of the epiglottis, which on being released from the thyroid cartilage had become tilted upwards and backwards, was drawn down and fixed to the centre of the upper border of the thyroid cartilage by means of a medium-sized wire suture; then, by means of a curved mounted needle, a strong wire was passed on either side through the upper part of the lateral wing of the thyroid cartilage and carried around the hyoid bone; on tightening these two sutures the deep soft parts were brought neatly together, and the hyoid bone maintained in its proper relation to the thyroid cartilage; finally, the surface wound was neatly closed over the deep sutures by means of fine silver wire. The man was kept in bed surrounded by a tent, the temperature of the room maintained at 65°, and the air constantly moistened by a steam kettle; two ounces of sanitas to each large kettleful of water served very well to keep the atmosphere pleasant and sweet. He was ordered to have milk and beef-tea thrice daily through an œsophageal tube, also beef-tea night and morning by the rectum. He was troubled a little with slight bronchial irritation for a few days afterwards, but his temperature never rose above 102·2°. The greater part of the wound united rapidly, leaving only a fine fistulous tract leading from the pharynx to the right angle of the cicatrix. As this opening showed no tendency to heal, a plastic procedure was resorted to on Aug. 29th—viz., the tract was thoroughly scraped with a Volckmann's spoon, and the walls of the fistula brought together by means of a strong deep suture; this was then covered in by bringing together the edges of the previously dissected up skin. This wound united kindly, and on Sept. 12th the tracheotomy tube was removed, and on the 18th (a week before his discharge), this last wound having closed, the patient was permitted to take soft solid food by the mouth.

Remarks by Mr. Harrison.—This wound was so large that it was quite out of the question to leave it to heal without maintaining the divided structures in good position, and moreover, to this end, it appeared a necessity to have free respiration below the site of injury. Similar treatment seems to suggest itself as commendable and safe for wounds of much less extent than the above, if not, indeed, to all cases of cut-throat whenever the pharynx or larynx has been laid in communication with the surface of the neck. The four deep sutures used had, up to the time of the patient's discharge, shown no symptoms of causing any trouble. The man has not been heard of at the infirmary since his discharge in a mood far from penitent.

SHEFFIELD GENERAL INFIRMARY.

A SERIES OF UNCOMMON GROWTHS.

(Under the care of Messrs. Favell and A. Jackson.)

For the following notes we are indebted to Mr. Charles Atkin, house-surgeon.

Case 1. *Congenital Coccygeal Tumour; Removal; Death; Necropsy.*—M. L——, aged four months, was brought to the infirmary for a swelling of the upper part and right side of the buttock. The lump was noticed at birth, and it was doubtful whether it had increased at all since, but the parents wished something to be done if possible, as they imagined it interfered with the well-being of the child. The father is phthisical; the mother, strong and healthy, gives a history of fright and a fall whilst pregnant with the child, which at its birth had "convulsions." Up to the present it, however, had only suffered from sleeplessness and gastric disturbances. On examination a semi-solid mass the size of a small orange was found protruding from the right side of the sacrum; it apparently increased in size on crying; the skin over it was adherent, nævoid, and puckered; it involved the coccyx, no extremity being detected. On the left side of the middle line the sacrum was entirely wanting, and the movement of the abdominal contents could easily be detected when the child cried. Double equino varus was also present. Mr. Jackson determined to explore it; so a small incision was made on the most solid portion of the swelling and the skin carefully dissected away. On the growth being removed, it was discovered that the rectum lay uncovered beneath. The tumour was then seen to consist of a mass of lobules, chiefly of hard dense fat bound together by connective tissue; interspersed were small cartilaginous masses, and one or two cysts about the size of a pea, containing opaque pale-green fluid, which under the microscope showed nothing but epithelial and cellular débris. The child progressed favourably for three days, taking the breast well, and then, unaccountably, rapidly failed and sank. At the autopsy the remains of a tumour were found attached by a pedicle to the right half of the sacrum; the left side was deficient, being only represented by a fibrous band. The growth did not encroach on the anterior surface; there was no meningitis, and the organs were healthy. Microscopically, the greater portion of the tumour removed was found to consist of fat and bundles of wavy fibrous tissue; the arteries were numerous and well formed; masses of hyaline cartilage, of most irregular shapes, were embedded in fibrous tissue; there were cysts, with thin regularly concentric walls, filled with semi-transparent yellowish granular material; and, most curious of all, transverse sections of what appeared to be well-made ducts lined with nucleated columnar-celled epithelium. These ducts were closely aggregated together in a mass of fibrous tissue; in some the epithelium was so well developed that it completely filled up the lumen of the tube, and gave the appearance of a rosette, a central axis with radiating spokes; in others the cells had shrunken from the walls towards the centre; in others, again, the cells were absent, no doubt washed away in the process of mounting. In no place was there any trace of sarcomatous or carcinoma cells, or any arrangement of tissue or cells at all resembling them. There was no trace of any bony tissue or hairs.

Case 2. *Epithelioma of the Ear, involving the Facial Nerve.*—T. H——, aged seventy-seven, was admitted into the infirmary in a very debilitated condition. His previous history had been very good; never had syphilis or any serious illness; no history of cancer in the family. Had noticed a wart on his left ear for the last five years, which used to bleed when it was knocked or rubbed by his hat. He went to a quack, who cauterised it with some strong acid twelve months ago; the wart never returned, but the sore thereby induced never healed. It has gradually increased in size, and occasionally bleeds very violently, especially after a fit of coughing. On examination the whole of the pinna was found to have been replaced by a mass of ulcerating new growth; the edges were raised, everted slightly, and indurated; the neighbouring skin, especially about the mastoid region, was dusky red and brawny, evidently infiltrated with new growth. The discharge consisted of sanious pus, foul smelling, but not very profuse. Under the microscope epithelioid cells were found. On the whole there were well-marked evidences of "new growth," though so much ulceration was present. There were also inability to close the eye, falling of the angle of the mouth, deviation of the tongue to the left on protrusion, all tending to show that the infiltration had reached and invaded the facial nerve. He was also completely deaf on the left side. The case having evidently gone too far for operation, he was kept in and watched, for some months he lingered, ultimately dying of exhaustion, partly induced by extensive bedsores which he had acquired previous to his entry into the infirmary. Microscopic sections of the growth showed it to be a typical epithelioma.

Case 3. *Congenital Sublingual Dermoid Cyst; Operation; Recovery.*—E. O——, a girl of seventeen, applied at the infirmary with a swelling underneath her tongue as large as a small orange; it filled her mouth, nearly completely forcing the tongue up against the palate, so that she could not possibly swallow solids. She was otherwise healthy, and stated that she had always a small lump there as long as she could remember, but that it had only increased in size the last nine months. She had already been under a medical man, who had first treated it with a seton and then incised it; but it had returned and increased beyond its former bulk. On seizing the front portion of it with forceps and snipping away a considerable part of the anterior wall, a large quantity of thick sebaceous matter presented itself, in which hairs were intermixed. The wound rapidly contracted and healed, and there has been no return, nine months after.

Case 4. *Large Epithelioma of the Lower Lip in a Female; Operation; no Recurrence a year later.*—R. W——, aged thirty-seven, stated that she was married, no children, always been very strong and healthy, and knew of no "lumps or sores" in the family. Ten months ago she first noticed something wrong with her lower lip; a pimple formed at the edge, then a crack, which continually scabbed over. On examination, the edge of the lower lip was found to consist of a dirty, dark, discharging ulcer, extending from the median line to the angle of the mouth on the right side. Below it the skin was hard, tender, dark-red, and irregularly raised, extending two inches and a half downwards and outwards; in fact, the ulcer and infiltrated skin comprised the whole distance from the edge of the lip to the lower border of the jaw, and behind to the anterior edge of the masseter muscle. In appearance she was stout and plethoric-looking. She had no sharp bad teeth, no mole on the lower lip, though there was on the upper. She can assign no cause, as she has never irritated her lips. The ulcer and neighbouring skin were completely removed by Mr. Favell, the parts coming together only at the expense of the size of her mouth; however, healing took place perfectly, and though her mouth was very much diminished in size, she went out very well satisfied with her personal appearance. It is now exactly twelve months ago since the operation, and there has been no recurrence of the disease. Under the microscope the specimen is seen to be a perfect one of epithelioma.
